Dedication

I dedicate this book to Adrienne and Jeremy. You are the future.

This page intentionally left blank

Acknowledgments

I would like to thank Executive Editor Bob Stern of Taylor & Francis Group, who envisioned this project (both the first and second editions) and whose enthusiasm and support have helped carry it to completion, Project Editor Michele Dimont, whose care and attention to detail improved the second edition, and Cover Designer Kevin Craig, who designed the covers for both the first and second editions.

I would like to thank the many authors whose work appears in this volume for the contributions of their time and expertise to this project, and for their patience with the revisions necessary to produce a unified whole from many parts.

Without the help of the associate editors for the second edition, Richard Brualdi and Pete Stewart, and the associate editors for the first edition, Richard Brualdi, Anne Greenbaum, and Roy Mathias, this book would not have been possible. They have given freely of their time, expertise, friendship, and moral support, and I cannot thank them enough.

I thank Iowa State University for providing a collegial and supportive environment in which to work, not only during the preparation of this book, but for more than 35 years. I thank the American Institute of Mathematics for enriching my professional life the past six years.

Last but certainly not least, I thank my husband, Mark Hunacek, both for his support throughout this project and for our wonderful life together.

Leslie Hogben

The Editor

Photograph by Sue Ellen Tuttle

Leslie Hogben is the Dio Lewis Holl Chair in Applied Mathematics and Professor of Mathematics at Iowa State University, and the Associate Director for Diversity of the American Institute of Mathematics.

She received her B.A. from Swarthmore College in 1974, and her Ph.D. in 1978 from Yale University under the direction of Nathan Jacobson. Although originally working in nonassociative algebras, in the mid-1990s she changed her focus to linear algebra.

Dr. Hogben is the author of more than 70 research papers and particularly enjoys introducing students to mathematical research. She has or is advising three postdoctoral associates, twelve doctoral students, twelve master's students, and thirty undergraduate researchers. She is the co-director of the NSF-sponsored ISU Math REU and developed an early graduate research (EGR) course for mathematics and applied mathematics graduate students at ISU.

Dr. Hogben is a frequent co-organizer of meetings, workshops, and special sessions/minisymposia. She is the Secretary/Treasurer of the International Linear Algebra Society and an associate editor of the journals *Linear Algebra and its Applications* and *Electronic Journal of Linear Algebra*.

The Associate Editors (2nd Edition)

Richard A. Brualdi is Bascom Professor of Mathematics, Emeritus at the University of Wisconsin-Madison. His primary mathematical interests are in combinatorics and matrix theory, with an emphasis on combinatorial matrix theory. He is a former president of the International Linear Algebra Society (ILAS), which in 2006 awarded him the Hans Schneider Linear Algebra Prize for lifetime contributions. In 2000 he was awarded the Euler Medal by the Institute of Combinatorics and its Applications (ICA) for distinguished contributions to combinatorial research. He currently serves as one of the editors-in-chief of *Linear Algebra and its Applications* and the *Electronic Journal of Combinatorics.*

G. W. (Pete) Stewart is a Distinguished University Professor, Emeritus in the Computer Science Department and Institute for Advanced Computer Studies at the University of Maryland, College Park. His research interests are in numerical linear algebra, scientific computing, and perturbation theory. He is a member of the National Academy of Engineering, a fellow of the Society of Industrial and Applied Mathematics. In 1996 he was awarded the F. L. Bauer Prize by the Technical University of Munich.

The Associate Editors (1st Edition)

Richard A. Brualdi is Bascom Professor of Mathematics, Emeritus at the University of Wisconsin-Madison. His primary mathematical interests are in combinatorics and matrix theory, with an emphasis on combinatorial matrix theory. He is a former president of the International Linear Algebra Society (ILAS), which in 2006 awarded him the Hans Schneider Linear Algebra Prize for lifetime contributions. In 2000 he was awarded the Euler Medal by the Institute of Combinatorics and its Applications (ICA) for distinguished contributions to combinatorial research. He currently serves as one of the editors-in-chief of *Linear Algebra and its Applications* and the *Electronic Journal of Combinatorics.*

Anne Greenbaum is a professor of applied mathematics at the University of Washington. Her main areas of research are applied linear algebra and numerical analysis. She is the author of *Iterative Methods for Solving Linear Systems*, published by SIAM in 1997, and recently wrote a book with Tim Chartier entitled *Numerical Methods: Design, Analysis, and Computer Implementation of Algorithms*, published by Princeton University Press in 2012.

Roy Mathias' mathematical interests are in matrix inequalities and eigenvalue computations. He has taught at the College of William and Mary, and the University of Birmingham, England, where he held a chair in Applied Mathematics. He has received SIAM awards for the best paper in applied linear algebra (2003) and outstanding paper in all SIAM journals (2005). He retired from mathematics in 2010 and lives in Oxfordshire.

Preface

Preface to the Second Edition

Both the format and guiding vision of *Handbook of Linear Algebra* remain unchanged, but a substantial amount of new material has been included in the second edition. The length has increased from 1400 pages to 1900 pages.

There are 20 new chapters. Subjects such as Schur complements, special types of matrices, generalized inverses, matrices over finite fields, and invariant subspaces are now treated in separate chapters. There are additional chapters on applications of linear algebra, for example, to epidemiology. There is a new chapter on using the free open source computer mathematics system *Sage* for linear algebra, which also provides a general introduction to *Sage*. Additional surveys of currently active research topics such as tournaments are also included.

Many of the existing articles have been revised and updated, in some cases adding a substantial amount of new material. For example, the chapters on sign pattern matrices and on applications to geometry have additional sections. As was true in the first edition, the topics range from the most basic linear algebra to advanced topics including background for active research areas. In this edition, many of the chapters on advanced topics now include Conjectures and Open Problems, either as a part of some sections or as a new section at the end of the chapter. The conjectures and questions listed in such sections have been in the literature for more than five years at the time of writing, and often a number of partial results have been obtained. In most cases, the current (at the time of writing) state of research related to the question is summarized as facts. Of course, there is no guarantee that (years after the writing date) such problems have not been solved (in fact, we hope they have been).

Updates and Feedback

This edition includes all known corrections to the first edition, and as in the case of the first edition, a list of any corrections to the second edition will be maintained at

`http://orion.math.iastate.edu/lhogben/HLA.html`.

As open problems included in the second edition are solved, a list of references for such solutions will also be maintained there. To report an error or a solution, please e-mail Leslie Hogben at `lhogben@iastate.edu` with *HLA* in the subject heading.

Preface to the First Edition

It is no exaggeration to say that linear algebra is a subject of central importance in both mathematics and a variety of other disciplines. It is used by virtually all mathematicians and by statisticians, physicists, biologists, computer scientists, engineers, and social scientists. Just as the basic idea of first semester differential calculus (approximating the graph of a function by its tangent line) provides information about the function, the process of linearization often allows difficult problems to be approximated by more manageable linear ones. This can provide insight into, and, thanks to ever-more-powerful computers, approximate solutions of the original problem. For this reason, people working in all the disciplines referred to above should find the *Handbook of Linear Algebra* an invaluable resource.

The *Handbook* is the first resource that presents complete coverage of linear algebra, combinatorial linear algebra, and numerical linear algebra, combined with extensive applications to a variety of fields and information on software packages for linear algebra in an easy to use handbook format.

Content

The *Handbook* covers the major topics of linear algebra at both the graduate and undergraduate level as well as its offshoots (numerical linear algebra and combinatorial linear algebra), its applications, and software packages for linear algebra computations. The *Handbook* takes the reader from the very elementary aspects of the subject to the frontiers of current research, and its format (consisting of a number of independent chapters each organized in the same standard way) should make this book accessible to readers with divergent backgrounds.

Format

There are five main parts in this book. The first part (Chapters 1 through Chapter 26) covers linear algebra; the second (Chapter 27 through Chapter 36) and third (Chapter 37 through Chapter 49) cover, respectively, combinatorial and numerical linear algebra, two important branches of the subject. Applications of linear algebra to other disciplines, both inside and outside of mathematics, comprise the fourth part of the book (Chapter 50 through Chapter 70). Part five (Chapter 71 through Chapter 77) addresses software packages useful for linear algebra computations.

Each chapter is written by a different author or team of authors, who are experts in the area covered. Each chapter is divided into sections, which are organized into the following uniform format:

- Definitions
- Facts
- Examples

Most relevant definitions appear within the Definitions segment of each chapter, but some terms that are used throughout linear algebra are not redefined in each chapter. The Glossary, covering the terminology of linear algebra, combinatorial linear algebra, and numerical linear algebra, is available at the end of the book to provide definitions of terms that appear in different chapters. In addition to the definition, the Glossary also provides the number of the chapter (and section, thereof) where the term is defined. The Notation Index serves the same purpose for symbols.

The Facts (which elsewhere might be called theorems, lemmas, etc.) are presented in list format, which allows the reader to locate desired information quickly. In lieu of proofs, references are provided for all facts. The references will also, of course, supply a source of additional information about the subject of the chapter. In this spirit, we have encouraged the authors to use texts or survey articles on the subject as references, where available.

The Examples illustrate the definitions and facts. Each section is short enough that it is easy to go back and forth between the Definitions/Facts and the Examples to see the illustration of a fact or definition. Some sections also contain brief applications following the Examples (major applications are treated in their own chapters).

This page intentionally left blank

Preliminaries

This chapter contains a variety of definitions of terms that are used throughout the rest of the book, but are not part of linear algebra or do not fit naturally into another chapter. Since these definitions have little connection with each other, a different organization is followed; the definitions are (loosely) alphabetized and each definition is followed by an example.

Algebra

An **(associative) algebra** is a vector space A over a field F together with a **multiplication** $(\mathbf{x}, \mathbf{y}) \mapsto \mathbf{xy}$ from $A \times A$ to A satisfying two *distributive* properties and *associativity*, i.e., for all $a, b \in F$ and all $\mathbf{x}, \mathbf{y}, \mathbf{z} \in A$:

$$(a\mathbf{x} + b\mathbf{y})\mathbf{z} = a(\mathbf{xz}) + b(\mathbf{yz}), \qquad \mathbf{x}(a\mathbf{y} + b\mathbf{z}) = a(\mathbf{xy}) + b(\mathbf{xz}) \qquad (\mathbf{xy})\mathbf{z} = \mathbf{x}(\mathbf{yz}).$$

Except in Chapter 86 and Chapter 87 the term *algebra* means associative algebra. In these two chapters, associativity is not assumed.

Examples:

1. The vector space of $n \times n$ matrices over a field F with matrix multiplication is an (associative) algebra.

Big-oh, Big-theta, Big-omega (asymptotic comparison)

See **O**.

Boundary

The **boundary** ∂S of a subset S of the real numbers or the complex numbers is the intersection of the closure of S and the closure of the complement of S.

Examples:

1. The boundary of $S = \{x \in \mathbb{C} : |z| \leq 1\}$ is $\partial S = \{x \in \mathbb{C} : |z| = 1\}$.

Complement

The **complement** of the set X in universe S, denoted $S \setminus X$, is all elements of S that are not in X. When the universe is clear (frequently the universe is $\{1, \ldots, n\}$), then this can be denoted X^c.

Examples:

1. For $S = \{1, 2, 3, 4, 5\}$ and $X = \{1, 3\}$, $S \setminus X = \{2, 4, 5\}$.

Complex Numbers

Let $a, b \in \mathbb{R}$. The symbol i denotes $\sqrt{-1}$.

The **complex conjugate** of a complex number $c = a + bi$ is $\overline{c} = a - bi$.

The **imaginary part** of $a + bi$ is $\text{im}(a + bi) = b$ and the **real part** is $\text{re}(a + bi) = a$.

The **absolute value** of $c = a + bi$ is $|c| = \sqrt{a^2 + b^2}$.

The **argument** of the nonzero complex number $re^{i\theta}$ is θ (with $r, \theta \in \mathbb{R}$ and $0 < r$ and $0 \leq \theta < 2\pi$).

The **open right half-plane** $\mathbb{C}^+$ is $\{z \in \mathbb{C} : \text{re}(z) > 0\}$.

The **closed right half-plane** $\mathbb{C}_0^+$ is $\{z \in \mathbb{C} : \text{re}(z) \geq 0\}$.

The **open left half-plane** $\mathbb{C}^-$ is $\{z \in \mathbb{C} : \text{re}(z) < 0\}$.

The **closed left half-plane** $\mathbb{C}^-$ is $\{z \in \mathbb{C} : \text{re}(z) \leq 0\}$.

Facts:

1. $|c| = \sqrt{c\overline{c}}$
2. $|re^{i\theta}| = r$
3. $re^{i\theta} = r\cos\theta + (r\sin\theta)i$
4. $\overline{re^{i\theta}} = re^{-i\theta}$

Examples:

1. $\overline{2 + 3i} = 2 - 3i$.
2. $\overline{1.4} = 1.4$.
3. $1 + i = \sqrt{2}e^{i\pi/4}$.

Conjugate Partition

Let $\upsilon = (u_1, u_2, \ldots, u_n)$ be a sequence of integers such that $u_1 \geq u_2 \geq \cdots \geq u_n \geq 0$. The **conjugate partition** of υ is $\upsilon^* = (u_1^*, \ldots, u_t^*)$, where u_i^* is the number of js such that $u_j \geq i$. t is sometimes taken to be u_1, but is sometimes greater (obtained by extending with 0s).

Facts:

1. If t is chosen to be the minimum, and $u_n > 0$, $\upsilon^{**} = \upsilon$.

Examples:

1. $(4, 3, 2, 2, 1)^* = (5, 4, 2, 1)$.

Convexity

Let V be a real or complex vector space.

Let $\{\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k\} \in V$. A vector of the form $a_1\mathbf{v}_1 + a_2\mathbf{v}_2 + \cdots + a_k\mathbf{v}_k$ with all the coefficients a_i nonnegative and $\sum a_i = 1$ is a **convex combination** of $\{\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k\}$.

A set $S \subseteq V$ is **convex** if any convex combination of vectors in S is in S.

The **convex hull** of S is the set of all convex combinations of S and is denoted by $\text{Con}(S)$.

An **extreme point** of a closed convex set S is a point $\mathbf{v} \in S$ that is not a nontrivial convex combination of other points in S, i.e., $a\mathbf{x} + (1 - a)\mathbf{y} = \mathbf{v}$ and $0 \leq a \leq 1$ implies $\mathbf{x} = \mathbf{y} = \mathbf{v}$.

A **convex polytope** is the convex hull of a finite set of vectors in $\mathbb{R}^n$.

Let $S \subseteq V$ be convex. A function $f : S \to \mathbb{R}$ is **convex** if for all $a \in \mathbb{R}$, $0 < a < 1$, $\mathbf{x}, \mathbf{y} \in S$, $f(a\mathbf{x} + (1 - a)\mathbf{y}) \leq af(\mathbf{x}) + (1 - a)f(\mathbf{y})$.

Facts:

1. A set $S \subseteq V$ is convex if and only if $\text{Con}(S) = S$.

2. The extreme points of Con(S) are contained in S.
3. [HJ85, pp. 533-534] *Krein-Milman Theorem*: A compact convex set is the convex hull of its extreme points.

Examples:

1. $[1.9, 0.8]^T$ is a convex combination of $[1, -1]^T$ and $[2, 1]^T$, since $[1.9, 0.8]^T = 0.1[1, -1]^T + 0.9[2, 1]^T$.
2. The set K of all $\mathbf{v} \in \mathbb{R}^3$ such that $v_i \geq 0, i = 1, 2, 3$ is a convex set. Its only extreme point is the zero vector.

Elementary Symmetric Function

The k**th elementary symmetric function of** $\alpha_i, i = 1, \ldots, n$ is

$$S_k(\alpha_1, \ldots, \alpha_n) = \sum_{1<i_1<i_2<\cdots<i_k<n} \alpha_{i_1}\alpha_{i_2}\ldots\alpha_{i_k}.$$

Examples:

1. $S_2(\alpha_1, \alpha_2, \alpha_3) = \alpha_1\alpha_2 + \alpha_1\alpha_3 + \alpha_2\alpha_3$,
$S_1(\alpha_1, \ldots, \alpha_n) = \alpha_1 + \alpha_2 + \cdots + \alpha_n$, $S_n(\alpha_1, \ldots, \alpha_n) = \alpha_1\alpha_2\ldots\alpha_n$.

Equivalence Relation

A binary relation $\equiv$ in a nonempty set S is an **equivalence relation** if it satisfies the following conditions:

1. (Reflexive) For all $a \in S$, $a \equiv a$.
2. (Symmetric) For all $a, b \in S$, $a \equiv b$ implies $b \equiv a$.
3. (Transitive) For all $a, b, c \in S$, $a \equiv b$ and $b \equiv c$ imply $a \equiv c$.

Examples:

1. Congruence mod n is an equivalence relation on the integers.

Field

A **field** is a set F with at least two elements together with a function $F \times F \to F$ called addition, denoted $(a, b) \to a + b$, and a function $F \times F \to F$ called multiplication, denoted $(a, b) \to ab$, which satisfy the following axioms:

1. (Commutativity) For each $a, b \in F$, $a + b = b + a$ and $ab = ba$.
2. (Associativity) For each $a, b, c \in F$, $(a + b) + c = a + (b + c)$ and $(ab)c = a(bc)$.
3. (Identities) There exist two elements 0 and 1 in F such that $0 + a = a$ and $1a = a$ for each $a \in F$.
4. (Inverses) For each $a \in F$, there exists an element $-a \in F$ such that $(-a) + a = 0$. For each nonzero $a \in F$, there exists an element $a^{-1} \in F$ such that $a^{-1}a = 1$.
5. (Distributivity) For each $a, b, c \in F, a(b + c) = ab + ac$.

Examples:

1. The real numbers, $\mathbb{R}$, the complex numbers, $\mathbb{C}$, and the rational numbers, $\mathbb{Q}$, are all fields. The set of integers, $\mathbb{Z}$, is not a field.

Gradient

Let f be a real or complex function of the (real or complex) variables $x_1, \ldots, x_n$. The **gradient** $\nabla f(y_1, \ldots, y_m)$ is the n-vector valued function with ith coordinate $\frac{\partial f}{\partial x_i}$.

Examples:

1. For $f(x_1, x_2, x_3) = x_1 x_2 + 4x_2 x_3$, $\nabla f = [x_2, x_1 + 4x_3, 4x_2]^T$.

Greatest Integer Function

The **greatest integer** or **floor** function $\lfloor x \rfloor$ (defined on the real numbers) is the greatest integer less than or equal to x.

Examples:

1. $\lfloor 1.5 \rfloor = 1$, $\lfloor 1 \rfloor = 1$, $\lfloor -1.5 \rfloor = -2$.

Group

(See also Chapter 84 and Chapter 85.)

A **group** is a nonempty set G with a function $G \times G \to G$ denoted $(a, b) \to ab$, which satisfies the following axioms:

1. (Associativity) For each $a, b, c \in G$, $(ab)c = a(bc)$.
2. (Identity) There exists an element $e \in G$ such that $ea = a = ae$ for each $a \in G$.
3. (Inverses) For each $a \in G$, there exists an element $a^{-1} \in G$ such that $a^{-1}a = e = aa^{-1}$.

A group is **abelian** if $ab = ba$ for all $a, b \in G$.

Let G and H be groups. A function $\varphi : G \to H$ is a *homomorphism* if $\varphi(gg') = \varphi(g)\varphi(g')$ for all $g, g' \in G$.

Examples:

1. Any vector space is an abelian group under $+$.
2. The set of invertible $n \times n$ real matrices is a group under matrix multiplication.
3. The set of all permutations of a set is a group under composition.

Interlaces

Let $a_1 \geq a_2 \geq \cdots \geq a_n$ and $b_1 \geq b_2 \geq \cdots \geq b_{n-1}$, two sequences of real numbers arranged in decreasing order.

The sequence $\{b_i\}$ **interlaces** the sequence $\{a_i\}$ if $a_n \leq b_{n-1} \leq a_{n-1} \cdots \leq b_1 \leq a_1$.

If all of the above inequalities are strict, the sequence $\{b_i\}$ **strictly interlaces** the sequence $\{a_i\}$.

Analogous definitions are given when the numbers are in increasing order.

Examples:

1. $7 \geq 2.2 \geq -1$ strictly interlaces $11 \geq \pi \geq 0 \geq -2.6$.

Little-oh (asymptotic comparison)

See **O**.

Majorization

Let $\alpha = (a_1, a_2, \ldots, a_n)$, $\beta = (b_1, b_2, \ldots, b_n)$ be sequences of real numbers.

$\alpha^{\downarrow} = (a_1^{\downarrow}, a_2^{\downarrow}, \ldots, a_n^{\downarrow})$ is the permutation of α with entries in nonincreasing order, i.e., $a_1^{\downarrow} \geq a_2^{\downarrow} \geq \ldots \geq a_n^{\downarrow}$.

$\alpha^{\uparrow} = (a_1^{\uparrow}, a_2^{\uparrow}, \ldots, a_n^{\uparrow})$ is the permutation of α with entries in nondecreasing order, i.e., $a_1^{\uparrow} \leq a_2^{\uparrow} \leq \ldots \leq a_n^{\uparrow}$.

α **weakly majorizes** β, written $\alpha \succeq_w \beta$ or $\beta \preceq_w \alpha$, if:

$$\sum_{i=1}^{k} a_i^{\downarrow} \geq \sum_{i=1}^{k} b_i^{\downarrow} \quad \text{for all } k = 1, \ldots n.$$

α **majorizes** β, written $\alpha \succeq \beta$ or $\beta \preceq \alpha$, if $\alpha \succeq_w \beta$ and $\sum_{i=1}^{n} a_i = \sum_{i=1}^{n} b_i$.

Examples:

1. If $\alpha = (2, 2, -1.3, 8, 7.7)$, then $\alpha^{\downarrow} = (8, 7.7, 2, 2, -1.3)$ and $\alpha^{\uparrow} = (-1.3, 2, 2, 7.7, 8)$.
2. (5,3,1.5,1.5,1) $\succeq$ (4,3,2,2,1) and (6,5,0) $\succeq_w$ (4,3,2).

Metric

A **metric** on a set S is a real-valued function $f : S \times S \to \mathbb{R}$ satisfying the following conditions for all $x, y \in S$:

1. $f(x, y) \geq 0$.
2. $f(x, x) = 0$.
3. $f(x, y) = 0$ implies $x = y$.
4. $f(x, y) = f(y, x)$.
5. $f(x, y) + f(y, z) \geq f(x, z)$.

A metric is intended as a measure of distance between elements of the set.

Examples:

1. If $\| \cdot \|$ is a norm on a vector space, then $f(x, y) = \|\mathbf{x} - \mathbf{y}\|$ is a metric.

Module

Let R be a ring with 1.

An R**-module** (or a **module over** R) is a set M together with a function $M \times M \to M$ called **addition**, denoted $(x, y) \to x + y$, and a function $R \times M \to M$ called **scalar multiplication** and denoted $(r, x) \to rx$, which satisfy the following axioms for $x, y, x \in V$ and $r, s \in R$:

1. (Commutativity of +) $x + y = y + x$.
2. (Associativity of +) $(x + y) + z = x + (y + z)$.
3. (Additive identity) There exists a **zero** in V, denoted by 0, such that for all $x \in M$, $0 + x = x$.
4. (Additive inverse) For each $x \in M$, there exists an **additive inverse** in V, denoted by $-x$, such that $-x + x = 0$.

5. (Distributivity) $r(x+y) = rx + ry$.
6. (Distributivity) $(r+s)x = rx + sx$.
7. (Associativity) $(rs)x = r(sx)$.
8. $1x = x$.

Technically what is defined here is a left module, and a right module can be defined analogously.

An R**-submodule** of an R-module M is a nonempty subset N of M that is closed under addition and scalar multiplication.

Let M be an R-module and let $X \subset M$. X is a **basis** or **set of free generators** for M if for every nonzero element m of M there exist unique nonzero elements $r_1, \ldots, r_k$ of R and unique $x_1, \ldots, x_k \in X$ such that $m = r_1x_1 + \cdots + r_kx_k$. M is **free** if it has a basis.

Let M and N be R-modules. A function $\varphi : M \to N$ is a **homomorphism** if $\varphi(x+y) = \varphi(x) + \varphi(y)$ and $\varphi(rx) = r\varphi(x)$ for all $x, y \in M$ and $r \in R$.

If M is an R-module, a **endomorphism** of M is a homomorphism $\varphi : M \to M$.

Facts:

1. If F is a field, then V is an F-module if and only if V is a vector space over F.
2. If F is a field, then every F-module is free.
3. The R-module R is a free R-module with basis $\{1\}$.
4. If M is an R-module, the set of endomorphisms of M with function addition and scalar multiplication is a ring (with the identity mapping as 1).
5. It is not the case that every module is free. See Example 4.
6. It is not the case that every submodule of a free R-module is free. See Example 4.
7. It is not the case that any two bases for a free R-module have the same number of elements (even if both are finite). See Example 5.
8. [Bla11, Proposition 2.2.10] If R is a division ring and M is a free R module, then any two bases have the same number of elements.
9. [Bla11, Proposition 2.2.11] If R is commutative and M is a free R module, then any two bases have the same number of elements.

Examples:

1. A left ideal of R is an R-module. In particular, for any $r \in R$, $Ra := \{ra : r \in R\}$ is an R-module.
2. Any abelian group (written additively) is a $\mathbb{Z}$-module.
3. Let R^n be the set of n-tuples of elements of R with addition and multiplication by elements of R defined coordinatewise (in the same way these operations are for the vectors space F^n, where F is a field). Then R^n is a free R-module.

Examples 4 – 7 illustrate some of the differences between modules and vector spaces.

4. Let F be a field and consider the ring $F[x]$ (the set of polynomials over F). Define
$$L = \{2p(x) + xq(x) : p(x), q(x) \in F[x]\}.$$
Then L is an $F[x]$-module that is not free (and is a submodule of the free $F[x]$-module $F[x]$).
5. [DF04, Exercise 10.3.27] Let $M = \{(a_1, a_2, a_3, \ldots) : a_i \in \mathbb{Z}\}$, viewed as a $\mathbb{Z}$-module with coordinatewise addition and scalar multiplication. Let R be the ring of endomorphisms of M (the identity mapping is denoted by 1), and view R as an R-module. Then R is free with basis $\{1\}$, but R also has basis with two elements: Define $\varphi_1((a_1, a_2, a_3, a_4, \ldots)) = (a_1, a_3, \ldots)$, $\varphi_2((a_1, a_2, a_3, a_4, \ldots)) = (a_2, a_4, \ldots)$, $\psi_1((a_1, a_2, a_3, a_4, \ldots)) = (a_1, 0, a_2, 0, \ldots)$, and $\psi_2((a_1, a_2, a_3, \ldots)) = (0, a_1, 0, a_2, \ldots)$. Then $\varphi_1\psi_1 = 1$, $\varphi_2\psi_2 = 1$, $\varphi_1\psi_2 = 0$, $\varphi_2\psi_1 = 0$, $\psi_1\varphi_1 + \psi_2\varphi_2 = 1$, and so $\{\varphi_1, \varphi_2\}$ is a basis for R.

6. Consider $\mathbb{Z}$ as a module over itself. Every element of $\mathbb{Z}$ can be written as a $\mathbb{Z}$-linear combination of the relatively prime integers 2 and 3, yet neither the set $\{2, 3\}$ nor any proper subset is a basis for $\mathbb{Z}$.
7. Consider $\mathbb{Z}$ as a module over itself. The set $\{2\}$ is "linearly independent" in the sense that $n \cdot 2 = 0$ implies $n = 0$ but the element 2 cannot be extended to a basis for $\mathbb{Z}$.
8. Let F be a field and let $A \in F^{n\times n}$. Then $F^{n\times n}$ is an $F[x]$-module with $p(x)B := p(A)B$.

Multiset

A **multiset** is an unordered list of elements that allows repetition.

Examples:

1. Any set is a multiset, but $\{1, 1, 3, -2, -2, -2\}$ is a multiset that is not a set.

NP, NP-hard

A problem is **NP** if a solution to the problem can be verified in polynomial time.

A problem H is **NP–hard** if any NP problem L can be converted to H by a polynomial time transformation of the inputs of L.

O, o, Θ, Ω (asymptotic comparison)

Let, f, g be real valued functions of $\mathbb{N}$ or $\mathbb{R}$, i.e., $f, g : \mathbb{N} \to \mathbb{R}$ or $f, g : \mathbb{R} \to \mathbb{R}$.

f is $O(g)$ (**big-oh** of g) if f does not grow faster than a constant multiple of g, i.e., there exist constants C, k such that $|f(x)| \leq C|g(x)|$ for all $x \geq k$.

f is $o(g)$ (**little-oh** of g) if $\lim_{x\to\infty} \left|\frac{f(x)}{g(x)}\right| = 0$.

f is $\Omega(g)$ (**big-omega** of g) if f grows at least as fast as a constant multiple of g, i.e., there exist constants C, k such that $|f(x)| \geq C|g(x)|$ for all $x \geq k$.

f is $\Theta(g)$ (**big-theta** of g) if f grows approximately as fast as a constant multiple of g, i.e., there exists a constant $C \neq 0$ such that $\lim_{x\to\infty} \left|\frac{f(x)}{g(x)}\right| = C$

Examples:

1. $x^2 + x$ is $O(x^2)$.
2. $\ln x$ is $o(x)$.

Path-connected

A subset S of the complex numbers is **path-connected** if for any $x, y \in S$ there exists a continuous function $p : [0, 1] \to S$ with $p(0) = x$ and $p(1) = y$.

Examples:

1. $S = \{z \in \mathbb{C} : 1 \leq |z| \leq 2\}$ and the line $\{a + bi : a = 2b + 3\}$ are path-connected.

Permutations

A **permutation** is a one-to-one onto function from a set to itself.

The set of permutations of $\{1, \ldots, n\}$ is denoted S_n.

The **identity permutation** maps every element of the set to itself and is denoted ε_n.

In this book, permutations are generally assumed to be elements of S_n for some n.

A **cycle** or **k-cycle** is a permutation τ such that there is a subset $\{a_1, \ldots, a_k\}$ of $\{1, \ldots, n\}$ satisfying $\tau(a_i) = a_{i+1}$ and $\tau(a_k) = a_1$; this is denoted $\tau = (a_1 a_2 \cdots a_k)$. The **length** of this cycle is k.

A **transposition** is a 2-cycle.

A permutation is **even** (respectively, **odd**) if it can be written as the product of an even (odd) number of transpositions.

The **sign** of a permutation τ, denoted sgn τ, is $+1$ if τ is even and -1 if τ is odd.

Note: Permutations are functions and act from the left (see Examples).

Facts:

1. Every permutation can be expressed as a product of disjoint cycles. This expression is unique up to the order of the cycles in the decomposition and cyclic permutation within a cycle.
2. Every permutation can be written as a product of transpositions. If some such expression includes an even number of transpositions, then every such expression includes an even number of transpositions.
3. S_n with the operation of composition is a group.

Examples:

1. If $\tau = (1523) \in S_6$, then $\tau(1) = 5, \tau(2) = 3, \tau(3) = 1, \tau(4) = 4, \tau(5) = 2, \tau(6) = 6$.
2. (123)(12)=(13).
3. $\text{sgn}(1234) = -1$ because $(1234) = (14)(13)(12)$.

Ring

(See also Section 32.1)

A **ring** is a set R together with a function $R \times R \to R$ called addition, denoted $(a, b) \to a+b$, and a function $R \times R \to R$ called multiplication, denoted $(a, b) \to ab$, which satisfy the following axioms:

1. (Commutativity of +) For each $a, b \in R$, $a + b = b + a$.
2. (Associativity) For each $a, b, c \in R$, $(a + b) + c = a + (b + c)$ and $(ab)c = a(bc)$.
3. (+ identity) There exists an element 0 in R such that $0 + a = a$.
4. (+ inverse) For each $a \in R$, there exists an element $-a \in R$ such that $(-a) + a = 0$.
5. (Distributivity) For each $a, b, c \in R, a(b + c) = ab + ac$ and $(a + b)c = ac + bc$.

A ring R **has a 1** if there is an element $1 \in R$ such that $1a = a = a1$ for all $a \in R$.

A ring R is **commutative** if $ab = ba$ for all $a, b \in R$.

A **zero divisor** in a ring R is a nonzero element $a \in R$ such that there exists a nonzero $b \in R$ with $ab = 0$ or $ba = 0$.

A subset L of a ring R is a **left ideal** of R if L is closed under addition and $rx \in L$ for all $r \in R$ and $x \in L$.

Let R and S be rings. A function $\varphi : R \to S$ is a **homomorphism** if $\varphi(x+y) = \varphi(x)+\varphi(y)$ and $\varphi(xy) = \varphi(x)\varphi(y)$ for all $x, y \in R$.

Examples:

1. The set of integers, $\mathbb{Z}$, is a commutative ring that has a 1.
2. Any field is a commutative ring that has a 1.
3. Let F be a field. Then the set of polynomials $F[x]$, with addition and multiplication of polynomials as the operations, is a ring.

4. Let F be a field. Then the set of $n \times n$ matrices $F^{n\times n}$, with matrix addition and matrix multiplication as the operations, is a ring. $E_{11} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$ and $E_{21} = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}$ are zero divisors since $E_{11}E_{21} = 0$. $F^{n\times n}$ is noncommutative because $E_{21}E_{11} = E_{21} \neq 0$. The identity matrix $I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ is a 1 for $F^{n\times n}$.
5. If R is a ring and $x \in R$, then $Rx := \{rx : r \in R\}$ is a left ideal of R.

Sign

(For sign of a permutation, see **Permutation**.)

The **sign** of a complex number is defined by:

$$\operatorname{sign}(z) = \begin{cases} z/|z|, & \text{if } z \neq 0; \\ 1, & \text{if } z = 0. \end{cases}$$

If z is a real number, this sign function yields 1 or -1. This sign function is used in numerical linear algebra.

The **sign** of a real number (as used in sign patterns) is defined by:

$$\operatorname{sgn}(a) = \begin{cases} +, & \text{if } a > 0; \\ 0, & \text{if } a = 0; \\ -, & \text{if } a < 0. \end{cases}$$

This sign function is used in combinatorial linear algebra, and the product of a sign and a real number is interpreted in the obvious way as a real number.

Warning: The two sign functions disagree on the sign of 0.

Examples:

1. $\operatorname{sgn}(-1.3) = -$, $\operatorname{sign}(-1.3) = -1$, $\operatorname{sgn}(0) = 0$, $\operatorname{sign}(0) = 1$, $\operatorname{sign}(1+i)=\dfrac{(1+i)}{\sqrt{2}}$.

Throughout this chapter, F will denote a field. The references [Lay12], [Leo10], and [SIF08] are good sources for more detail about much of the material in this chapter. They discuss primarily the field of real numbers, but the proofs are usually valid for any field. Vector spaces over a general field are presented in [FIS03]

1.1 Vector Spaces

Vectors are used in many applications. They often represent quantities that have both direction and magnitude, such as velocity or position relative to the origin. They can appear as functions, as n-tuples of scalars, matrices, or in other disguises. Whenever objects can be added and multiplied by scalars, they may be elements of some vector space. In this section, we formulate a general definition of vector space and establish its basic properties. An element of a field, such as the real numbers or the complex numbers, is called a scalar to distinguish it from a vector.

Definitions:

A **vector space over** F is a set V together with a function $V \times V \to V$ called **addition**, denoted $(\mathbf{x},\mathbf{y}) \to \mathbf{x} + \mathbf{y}$, and a function $F \times V \to V$ called **scalar multiplication** and denoted $(c,\mathbf{x}) \to c\mathbf{x}$, which satisfy the following axioms:

1. (Commutativity) For each $\mathbf{x}, \mathbf{y} \in V$, $\mathbf{x} + \mathbf{y} = \mathbf{y} + \mathbf{x}$.
2. (Associativity) For each $\mathbf{x}, \mathbf{y}, \mathbf{z} \in V$, $(\mathbf{x} + \mathbf{y}) + \mathbf{z} = \mathbf{x} + (\mathbf{y} + \mathbf{z})$.
3. (Additive identity) There exists a **zero vector** in V, denoted $\mathbf{0}$, such that $\mathbf{0} + \mathbf{x} = \mathbf{x}$ for each $\mathbf{x} \in V$.
4. (Additive inverse) For each $\mathbf{x} \in V$, there exists $-\mathbf{x} \in V$ such that $(-\mathbf{x}) + \mathbf{x} = \mathbf{0}$.
5. (Distributivity) For each $a \in F$ and $\mathbf{x}, \mathbf{y} \in V$, $a(\mathbf{x} + \mathbf{y}) = a\mathbf{x} + a\mathbf{y}$.
6. (Distributivity) For each $a, b \in F$ and $\mathbf{x} \in V$, $(a + b)\,\mathbf{x} = a\mathbf{x} + b\mathbf{x}$.
7. (Associativity) For each $a, b \in F$ and $\mathbf{x} \in V$, $(ab)\,\mathbf{x} = a(b\mathbf{x})$.
8. For each $\mathbf{x} \in V$, $1\mathbf{x} = \mathbf{x}$.

The properties that for all $\mathbf{x}, \mathbf{y} \in V$, and $a \in F$, $\mathbf{x} + \mathbf{y} \in V$ and $a\mathbf{x} \in V$, are called **closure under addition** and **closure under scalar multiplication**, respectively. The elements of a vector space V are called **vectors**. A vector space is called **real** if $F = \mathbb{R}$, and **complex** if $F = \mathbb{C}$.

If n is a positive integer, F^n denotes the set of all ordered n-tuples (written as columns). These are sometimes written instead as rows $[x_1 \quad \cdots \quad x_n]$ or $(x_1, \ldots, x_n)$. For $\mathbf{x} = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix}, \mathbf{y} = \begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix} \in F^n$ and $c \in F$, define addition and scalar multiplication coordinate-wise: $\mathbf{x} + \mathbf{y} = \begin{bmatrix} x_1 + y_1 \\ \vdots \\ x_n + y_n \end{bmatrix}$ and $c\mathbf{x} = \begin{bmatrix} cx_1 \\ \vdots \\ cx_n \end{bmatrix}$. Let $\mathbf{0}$ denote the n-tuple of zeros. For $\mathbf{x} \in F^n$, x_j is called the j$^{\text{th}}$ **coordinate** of $\mathbf{x}$.

A **subspace** of vector space V over field F is a subset of V, which is itself a vector space over F when the addition and scalar multiplication of V are used. If S_1 and S_2 are subsets of vector space V, define $S_1 + S_2 = \{\mathbf{x} + \mathbf{y} : \mathbf{x} \in S_1 \text{ and } \mathbf{y} \in S_2\}$.

Facts:

Let V be a vector space over F.

1. F^n is a vector space over F.
2. [FIS03, pp. 11–12] (Basic properties of a vector space):
   (a) The vector $\mathbf{0}$ is the only additive identity in V.
   (b) For each $\mathbf{x} \in V$, $-\mathbf{x}$ is the only additive inverse for $\mathbf{x}$ in V.
   (c) For each $\mathbf{x} \in V$, $-\mathbf{x} = (-1)\mathbf{x}$.
   (d) If $a \in F$ and $\mathbf{x} \in V$, then $a\mathbf{x} = \mathbf{0}$ if and only if $a = 0$ or $\mathbf{x} = \mathbf{0}$.
   (e) (Cancellation) If $\mathbf{x}, \mathbf{y}, \mathbf{z} \in V$ and $\mathbf{x} + \mathbf{y} = \mathbf{x} + \mathbf{z}$, then $\mathbf{y} = \mathbf{z}$.
3. [FIS03, pp. 16–17] Let W be a subset of V. The following are equivalent:
   (a) W is a subspace of V.
   (b) W is nonempty and closed under addition and scalar multiplication.
   (c) $\mathbf{0} \in W$ and for any $\mathbf{x}, \mathbf{y} \in W$ and $a, b \in F$, $a\mathbf{x} + b\mathbf{y} \in W$.
4. [FIS03, p. 16] For any vector space V, $\{\mathbf{0}\}$ and V itself are subspaces of V.
5. [FIS03, p. 19] The intersection of any nonempty collection of subspaces of V is a subspace of V.
6. [FIS03, p. 22] Let W_1 and W_2 be subspaces of V. Then $W_1 + W_2$ is a subspace of V containing W_1 and W_2. It is the smallest subspace that contains them in the sense that any subspace that contains both W_1 and W_2 must contain $W_1 + W_2$.

Examples:

1. The set $\mathbb{R}^n$ of all ordered n-tuples of real numbers is a vector space over $\mathbb{R}$. The set $\mathbb{C}^n$ of all ordered n-tuples of complex numbers is a vector space over $\mathbb{C}$. For instance, $\mathbf{x} = \begin{bmatrix} 3 \\ 0 \\ -1 \end{bmatrix}$ and $\mathbf{y} = \begin{bmatrix} 2i \\ 4 \\ 2 - 3i \end{bmatrix}$ are elements of $\mathbb{C}^3$; $\mathbf{x} + \mathbf{y} = \begin{bmatrix} 3 + 2i \\ 4 \\ 1 - 3i \end{bmatrix}, -\mathbf{y} = \begin{bmatrix} -2i \\ -4 \\ -2 + 3i \end{bmatrix}$, and $i\mathbf{y} = \begin{bmatrix} -2 \\ 4i \\ 3 + 2i \end{bmatrix}$.

2. Notice $\mathbb{R}^n$ is a subset of $\mathbb{C}^n$ but not a subspace of $\mathbb{C}^n$, since $\mathbb{R}^n$ is not closed under multiplication by nonreal numbers.
3. The vector spaces $\mathbb{R}$, $\mathbb{R}^2$, and $\mathbb{R}^3$ are the usual Euclidean spaces of analytic geometry. There are three types of subspaces of $\mathbb{R}^2$: $\{\mathbf{0}\}$, a line through the origin, and $\mathbb{R}^2$ itself. There are four types of subspaces of $\mathbb{R}^3$: $\{\mathbf{0}\}$, a line through the origin, a plane through the origin, and $\mathbb{R}^3$ itself. For instance, let $\mathbf{v} = (5, -1, -1)$ and $\mathbf{w} = (0, 3, -2)$. The lines $W_1 = \{s\mathbf{v} : s \in \mathbb{R}\}$ and $W_2 = \{s\mathbf{w} : s \in \mathbb{R}\}$ are subspaces of $\mathbb{R}^3$. The subspace $W_1 + W_2 = \{s\mathbf{v} + t\,\mathbf{w} : s, t \in \mathbb{R}\}$ is a plane. The set $\{s\mathbf{v} + \mathbf{w}\text{: } s \in \mathbb{R}\}$ is a line parallel to W_1, but is not a subspace. (For more information on geometry, see Chapter 82.)
4. Let $F[x]$ be the set of all polynomials in the single variable x, with coefficients from F. To add polynomials, add coefficients of like powers; to multiply a polynomial by an element of F, multiply each coefficient by that scalar. With these operations, $F[x]$ is a vector space over F. The zero polynomial z, with all coefficients 0, is the additive identity of $F[x]$. For $f \in F[x]$, the function $-f$ defined by $-f(x) = (-1)f(x)$ is the additive inverse of f.
5. In $F[x]$, the constant polynomials have degree 0. For $n > 0$, the polynomials with the highest power term x^n are said to have degree n. For a nonnegative integer n, let $F[x; n]$ be the subset of $F[x]$ consisting of all polynomials of degree n or less. Then $F[x; n]$ is a subspace of $F[x]$.
6. When $n > 0$, the set of all polynomials of degree exactly n is not a subspace of $F[x]$ because it is not closed under addition or scalar multiplication. The set of all polynomials in $\mathbb{R}[x]$ with rational coefficients is not a subspace of $\mathbb{R}[x]$ because it is not closed under scalar multiplication.
7. Let V be the set of all infinite sequences $(a_1, a_2, a_3, \ldots)$, where each $a_j \in F$. Define addition and scalar multiplication coordinate-wise. Then V is a vector space over F.
8. Let X be a nonempty set and let $\mathcal{F}(\mathcal{X}, \mathcal{F})$ be the set of all functions $f\colon X \to F$. Let f, $g \in \mathcal{F}(\mathcal{X}, \mathcal{F})$ and define $f + g$ and cf pointwise, as $(f + g)(x) = f(x) + g(x)$ and $(cf)(\text{x}) = cf(x)$ for all $x \in X$. With these operations, $\mathcal{F}(\mathcal{X}, \mathcal{F})$ is a vector space over F. The zero function is the additive identity and $(-1)f = -f$ is the additive inverse of f.
9. Let X be a nonempty subset of $\mathbb{R}^n$. The set $C(X)$ of all continuous functions $f\colon X \to \mathbb{R}$ is a subspace of $\mathcal{F}(\mathcal{X}, \mathbb{R})$. The set $\mathcal{D}(\mathcal{X})$ of all differentiable functions $f\colon X \to \mathbb{R}$ is a subspace of $C(X)$ and also of $\mathcal{F}(\mathcal{X}, \mathbb{R})$.

1.2 Matrices

Matrices are rectangular arrays of scalars that are used in a great variety of ways, such as to solve linear systems, model linear behavior, and approximate nonlinear behavior. They are standard tools in almost every discipline, from sociology to physics and engineering.

Definitions:

An $m \times p$ **matrix** over F is an $m \times p$ rectangular array $A = \begin{bmatrix} a_{11} & \cdots & a_{1p} \\ \vdots & \cdots & \vdots \\ a_{m1} & \cdots & a_{mp} \end{bmatrix}$, with entries from F. The notation $A = [a_{ij}]$ that displays a typical entry is also used. The element a_{ij} of the matrix A is called the (i, j) **entry** of A and can also be denoted $(A)_{ij}$. The **shape** (or **size**) of A is $m \times p$.

Matrix A is **square** if $m = p$.

Two matrices $A = [a_{ij}]$ and $B = [b_{ij}]$ are said to be **equal** if they have the same shape and $a_{ij} = b_{ij}$ for all i, j.

Let $A = [a_{ij}]$ and $B = [b_{ij}]$ be $m \times p$ matrices, and let c be a scalar. Define **addition** and **scalar multiplication** on the set of all $m \times p$ matrices over F entrywise, as $A + B = [a_{ij} + b_{ij}]$ and $cA = [ca_{ij}]$. The set of all $m \times p$ matrices over F with these operations is denoted $F^{m\times p}$.

If A is $m \times p$, **row** i is $[a_{i1}, \quad \ldots, \quad a_{ip}]$ and **column** j is $\begin{bmatrix} a_{1j} \\ \vdots \\ a_{mj} \end{bmatrix}$. These are called a **row vector** and a **column vector**, respectively, and they belong to $F^{n\times 1}$ and $F^{1\times n}$, respectively.

The elements of F^n are identified with the elements of $F^{n\times 1}$ (or sometimes with the elements of $F^{1\times n}$).

Let $\mathbf{0}_{mp}$ denote the $m \times p$ matrix of zeros, often shortened to $\mathbf{0}$ when the size is clear.

Define $-A = (-1)A$.

Let $A = [\mathbf{a}_1 \quad \ldots \quad \mathbf{a}_p] \in F^{m\times p}$, where $\mathbf{a}_j$ is the jth column of A, and let $\mathbf{b} \ = \begin{bmatrix} b_1 \\ \vdots \\ b_p \end{bmatrix} \in F^{p\times 1}$. The **matrix–vector product** of A and $\mathbf{b}$ is $A\mathbf{b} = b_1\mathbf{a}_1 + \cdots + b_p\mathbf{a}_p$. Notice $A\mathbf{b}$ is $m \times 1$.

If $A \in F^{m\times p}$ and $C = [\mathbf{c}_1 \quad \ldots \quad \mathbf{c}_n] \in F^{p\times n}$, define the **matrix product** of A and C as $AC = [A\mathbf{c}_1 \quad \ldots \quad A\mathbf{c}_n]$. Notice AC is $m \times n$.

Square matrices A and B **commute** if $AB = BA$.

When $i = j, a_{ii}$ is a **diagonal entry** of A and the set of all its diagonal entries is the **main diagonal** of A. When $i \neq j, a_{ij}$ is an **off-diagonal entry**.

The **trace** of A is the sum of all the diagonal entries of A, tr $A = \sum_{i=1}^{n} a_{ii}$.

A matrix $A = [a_{ij}]$ is **diagonal** if $a_{ij} = 0$ whenever $i \neq j$.

A matrix $A = [a_{ij}]$ is **lower triangular** if $a_{ij} = 0$ whenever $i < j$, and **upper triangular** if $a_{ij} = 0$ whenever $i > j$.

A **unit triangular** matrix is a lower or upper triangular matrix in which each diagonal entry is 1.

The **identity matrix** I_n, often shortened to I when the size is clear, is the $n \times n$ matrix with main diagonal entries 1 and other entries 0.

A **scalar matrix** is a scalar multiple of the identity matrix.

A **permutation matrix** is one whose rows are some rearrangement of the rows of an identity matrix.

Let $A \in F^{m\times p}$. The **transpose** of A, denoted A^T, is the $p \times m$ matrix whose (i, j) entry is the (j, i) entry of A.

The square matrix A is **symmetric** if $A^T = A$ and **skew-symmetric** if $A^T = -A$.

When $F = \mathbb{C}$, that is, when A has complex entries, the **Hermitian adjoint** of A is its conjugate transpose, $A^* = \bar{A}^T$; that is, the (i, j) entry of A^* is $\overline{a_{ji}}$. Some authors, such as [Leo10], write A^H instead of A^*.

The square matrix A is **Hermitian** if $A^* = A$ and **skew-Hermitian** if $A^* = -A$.

Let α be a nonempty set of row indices and β a nonempty set of column indices. A **submatrix** of A is a matrix $A[\alpha, \beta]$ obtained by choosing the entries of A, which lie in rows α and columns β.

A **principal submatrix** of A is a submatrix of the form $A[\alpha, \alpha]$.

A **leading principal submatrix** of A is one of the form $A[\{1, \ldots, k\}, \{1, \ldots, k\}]$.

Facts:

1. [SIF08, p. 6] $F^{m\times p}$ is a vector space over F. That is, if $\mathbf{0}$, A, B, $C \in F^{m\times p}$, and c,$d \in F$, then:
   (a) $A + B = B + A$
   (b) $(A + B) + C = A + (B + C)$
   (c) $A + \mathbf{0} = \mathbf{0} + A = A$
   (d) $A + (-A) = (-A) + A = \mathbf{0}$
   (e) $c(A + B) = cA + cB$
   (f) $(c + d)A = cA + dA$
   (g) $(cd)\ A = c(dA)$
   (h) $1A = A$

2. [SIF08, pp. 99–100] If $A \in F^{m\times p}$ and $C \in F^{p\times n}$, the (i,j) entry of AC is $(AC)_{ij} = \sum_{k=1}^{p} a_{ik}a_{kj}$. This is the matrix product of row i of A and column j of C.
3. [SIF08, p. 101] Let $c \in F$, let A and B be matrices over F, let I denote an identity matrix, and assume the shapes allow the following sums and products to be calculated. Then:
   (a) $AI = IA = A$
   (b) $A\mathbf{0} = \mathbf{0}$ and $\mathbf{0}A = \mathbf{0}$
   (c) $A(BC) = (AB)C$
   (d) $A(B+C) = AB + AC$
   (e) $(A+B)C = AC + BC$
   (f) $c(AB) = A(cB) = (cA)B$ for any scalar c
4. [SIF08, pp. 7, 101] Let $c \in F$, let A and B be matrices over F, and assume the shapes allow the following sums and products to be calculated. Then:
   (a) $(A^T)^T = A$
   (b) $(A+B)^T = A^T + B^T$
   (c) $(cA)^T = cA^T$
   (d) $(AB)^T = B^T A^T$
5. [Leo10, p. 326] Let $c \in \mathbb{C}$, let A and B be matrices over $\mathbb{C}$, and assume the shapes allow the following sums and products to be calculated. Then:
   (a) $(A^*)^* = A$
   (b) $(A+B)^* = A^* + B^*$
   (c) $(cA)^* = \bar{c}A^*$
   (d) $(AB)^* = B^*A^*$
6. [Leo10, p. 67], [SIF08, p. 105] If A and B are $n \times n$ and upper (lower) triangular, then AB is upper (lower) triangular.

Examples:

1. Let $A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$ and $\mathbf{b} = \begin{bmatrix} 7 \\ 8 \\ -9 \end{bmatrix}$. By definition, $A\mathbf{b} = 7\begin{bmatrix} 1 \\ 4 \end{bmatrix} + 8\begin{bmatrix} 2 \\ 5 \end{bmatrix} - 9\begin{bmatrix} 3 \\ 6 \end{bmatrix} = \begin{bmatrix} -4 \\ 14 \end{bmatrix}$. Hand calculation of $A\mathbf{b}$ can be done more quickly using Fact 2: $A\mathbf{b} = \begin{bmatrix} 1\cdot 7 + 2\cdot 8 - 3\cdot 9 \\ 4\cdot 7 + 5\cdot 8 - 6\cdot 9 \end{bmatrix} = \begin{bmatrix} -4 \\ 14 \end{bmatrix}$.
2. Let $A = \begin{bmatrix} 1 & -3 & 4 \\ 2 & 0 & 8 \end{bmatrix}$, $B = \begin{bmatrix} -3 & 8 & 0 \\ 1 & 2 & -5 \end{bmatrix}$, and $C = \begin{bmatrix} 1 & -1 & 8 \\ 1 & 3 & 0 \\ 1 & 2 & -2 \end{bmatrix}$. Then $A + B = \begin{bmatrix} -2 & 5 & 4 \\ 3 & 2 & 3 \end{bmatrix}$ and $2A = \begin{bmatrix} 2 & -6 & 8 \\ 4 & 0 & 16 \end{bmatrix}$. The matrices $A+C$, BA, and AB are not defined, but
$$AC = \begin{bmatrix} A\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} & A\begin{bmatrix} -1 \\ 3 \\ 2 \end{bmatrix} & A\begin{bmatrix} 8 \\ 0 \\ -2 \end{bmatrix} \end{bmatrix} = \begin{bmatrix} 2 & -2 & 0 \\ 10 & 14 & 0 \end{bmatrix}.$$
3. Even when the shapes of A and B allow both AB and BA to be calculated, AB and BA are not usually equal. For instance, let $A = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}$ and $B = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$; then $AB = \begin{bmatrix} a & b \\ 2c & 2d \end{bmatrix}$ and $BA = \begin{bmatrix} a & 2b \\ c & 2d \end{bmatrix}$, which will be equal only if $b = c = 0$.

4. The product of matrices can be a zero matrix even if neither has any zero entries. For example, if $A = \begin{bmatrix} 1 & -1 \\ 2 & -2 \end{bmatrix}$ and $B = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$, then $AB = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$. Notice that BA is also defined but has no zero entries: $BA = \begin{bmatrix} 3 & -3 \\ 3 & -3 \end{bmatrix}$.

5. The matrices $\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -9 \end{bmatrix}$ and $\begin{bmatrix} 1 & 0 & 0 \\ 0 & -3 & 0 \end{bmatrix}$ are diagonal, $\begin{bmatrix} 1 & 0 & 0 \\ 2 & 0 & 0 \\ 1 & 5 & -9 \end{bmatrix}$ and $\begin{bmatrix} 1 & 0 & 0 \\ 2 & -3 & 0 \end{bmatrix}$ are lower triangular, and $\begin{bmatrix} 1 & -4 & 7 \\ 0 & 1 & 2 \\ 0 & 0 & -9 \end{bmatrix}$ and $\begin{bmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$ are upper triangular. The matrix $\begin{bmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 1 & 5 & 1 \end{bmatrix}$ is unit lower triangular, and its transpose is unit upper triangular.

6. Examples of permutation matrices include every identity matrix, $\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, $\begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix}$, and $\begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$.

7. Let $A = \begin{bmatrix} 1+i & -3i & 4 \\ 1+2i & 5i & 0 \end{bmatrix}$. Then $A^T = \begin{bmatrix} 1+i & 1+2i \\ -3i & 5i \\ 4 & 0 \end{bmatrix}$ and $A^* = \begin{bmatrix} 1-i & 1-2i \\ 3i & -5i \\ 4 & 0 \end{bmatrix}$.

8. The matrices $\begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix}$ and $\begin{bmatrix} i & 2 & 3+2i \\ 2 & 4-i & 5i \\ 3+2i & 5i & 6 \end{bmatrix}$ are symmetric.

9. The matrices $\begin{bmatrix} 0 & 2 & 3 \\ -2 & 0 & 5 \\ -3 & -5 & 0 \end{bmatrix}$ and $\begin{bmatrix} 0 & 2 & 3+2i \\ -2 & 0 & -5 \\ -3-2i & 5 & 0 \end{bmatrix}$ are skew-symmetric.

10. The matrix $\begin{bmatrix} 1 & 2+i & 1-3i \\ 2-i & 0 & 1 \\ 1+3i & 1 & 6 \end{bmatrix}$ is Hermitian, and any real symmetric matrix, such as $\begin{bmatrix} 4 & 2 & 3 \\ 2 & 0 & 5 \\ 3 & 5 & -1 \end{bmatrix}$, is also Hermitian.

11. The matrix $\begin{bmatrix} i & 2 & -3+2i \\ -2 & 4i & 5 \\ 3+2i & -5 & 0 \end{bmatrix}$ is skew-Hermitian, and any real skew-symmetric ma-

trix, such as $\begin{bmatrix} 0 & 2 & -3 \\ -2 & 0 & 5 \\ 3 & -5 & 0 \end{bmatrix}$, is also skew-Hermitian.

12. Let $A = \begin{bmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{bmatrix}$. Row 1 of A is $[1 \quad 2 \quad 3 \quad 4]$, column 3 is $\begin{bmatrix} 3 \\ 7 \\ 11 \\ 15 \end{bmatrix}$, and the submatrix in rows {1, 2, 4} and columns {2, 3, 4} is $A[\{1,2,4\},\{2,3,4\}] = \begin{bmatrix} 2 & 3 & 4 \\ 6 & 7 & 8 \\ 14 & 15 & 16 \end{bmatrix}$. A principal submatrix of A is $A[\{1, 2, 4\}, \{1, 2, 4\}] = \begin{bmatrix} 1 & 2 & 4 \\ 5 & 6 & 8 \\ 13 & 14 & 16 \end{bmatrix}$. The leading principal submatrices of A are $[1]$, $\begin{bmatrix} 1 & 2 \\ 5 & 6 \end{bmatrix}$, $\begin{bmatrix} 1 & 2 & 3 \\ 5 & 6 & 7 \\ 9 & 10 & 11 \end{bmatrix}$, and A itself.

1.3 Gaussian and Gauss–Jordan Elimination

Definitions:

Let A be a matrix with m rows.

When a row of A is not zero, its first nonzero entry is the **leading entry** of the row. The matrix A is in **row echelon form** (REF) when the following two conditions are met:

1. Any zero rows are below all nonzero rows.
2. For each nonzero row $i, i \leq m - 1$, either row $i + 1$ is zero or the leading entry of row $i + 1$ is in a column to the right of the column of the leading entry in row i.

The matrix A is in **reduced row echelon form** (RREF) if it is in row echelon form and the following third condition is also met:

3. If a_{ik} is the leading entry in row i, then $a_{ik} = 1$, and every entry of column k other than a_{ik} is zero.

Elementary row operations on a matrix are operations of the following types:

1. Add a multiple of one row to a different row.
2. Exchange two different rows.
3. Multiply one row by a nonzero scalar.

The matrix A is **row equivalent** to the matrix B if there is a sequence of elementary row operations that transforms A into B.

The **reduced row echelon form** of A, RREF(A), is the matrix in reduced row echelon form that is row equivalent to A.

A **row echelon form of** A is any matrix in row echelon form that is row equivalent to A.

The **rank** of A, denoted rank A or rank(A), is the number of leading entries in RREF(A).

If A is in row echelon form, the positions of the leading entries in its nonzero rows are called **pivot positions** and the entries in those positions are called **pivots**. A column (row) that contains a pivot position is a **pivot column (pivot row)**.

Gaussian Elimination is a process that uses elementary row operations in a particular way to change, or reduce, a matrix to row echelon form.

Gauss–Jordan Elimination is a process that uses elementary row operations in a particular way to reduce a matrix to RREF. See Algorithm 1.

Facts:

Let $A \in F^{m \times p}$.

1. [Lay12, p. 13] The reduced row echelon form of A, $\text{RREF}(A)$, exists and is unique.
2. A matrix in REF or RREF is upper triangular.
3. [SIF08, p. 37] Every elementary row operation is reversible by an elementary row operation of the same type.
4. [Leo10, pp. 61, 67] If A is row equivalent to B, then B is row equivalent to A.
5. [Leo10, pp. 67, 154] If A is row equivalent to B, then $\text{RREF}(A) = \text{RREF}(B)$ and $\text{rank}\, A = \text{rank}\, B$.
6. If F is a subfield of a larger field K and $A \in F^{n \times n}$, then viewing $A \in K^{n \times n}$ does not change the reduced row echelon form or rank of A.
7. The number of nonzero rows in any row echelon form of A equals $\text{rank}\, A$.
8. If B is any row echelon form of A, the positions of the leading entries in B are the same as the positions of the leading entries of $\text{RREF}(A)$.
9. [Lay12, pp. 17, 20], [Leo10, pp. 391–402], [SIF08, pp. 152–167], and Sections 51.2 and 51.3 (Gaussian and Gauss–Jordan Elimination Algorithms) When one or more pivots are relatively small, using the algorithms below in floating point arithmetic can yield inaccurate results. (See Chapter 50 and [Leo10, pp. 386–417] for error analysis, and Chapter 93 for information on professional software implementations of these algorithms.)

Algorithm 1. Gaussian and Gauss-Jordan Elimination

Let $A \in F^{m \times p}$. Steps 1 to 4 below do Gaussian Elimination, reducing A to a matrix that is in row echelon form. Steps 1 to 6 do Gauss–Jordan Elimination, reducing A to $\text{RREF}(A)$.

1. Let $U = A$ and $r = 1$. If $U = \mathbf{0}$, U is in RREF.
2. If $U \neq \mathbf{0}$, search the submatrix of U in rows r to m to find its first nonzero column, k, and the first nonzero entry, a_{ik}, in this column. If $i > r$, exchange rows r and i in U, thus getting a nonzero entry in position (r, k). Let U denote the new matrix.
3. Add multiples of row r to the rows below it to create zeros in column k below row r. Let U denote the new matrix.
4. If either $r = m - 1$ or rows $r + 1, \ldots, m$ are all zero, U is now in REF. Otherwise, let $r = r + 1$ and repeat steps 2, 3, and 4.
5. Let $k_1, \ldots, k_s$ be the pivot columns of U, so $(1, k_1), \ldots, (s, k_s)$ are the pivot positions. For $i = s, s - 1, \ldots, 2$, add multiples of row i to the rows above it to create zeros in column k_i above row i.
6. For $i = 1, \ldots, s$, divide row s by its leading entry. The resulting matrix is $\text{RREF}(A)$.

Examples:

1. The RREF of a zero matrix is itself, and its rank is zero.
2. Let $A = \begin{bmatrix} 1 & 3 & 4 & -8 \\ 0 & 0 & 2 & 4 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ and $B = \begin{bmatrix} 1 & 3 & 4 & -8 \\ 0 & 0 & 0 & 4 \\ 0 & 0 & 1 & 0 \end{bmatrix}$. Both are upper triangular, but A is in REF and B is not. Use Gauss–Jordan Elimination to calculate $\text{RREF}(A)$ and $\text{RREF}(B)$:

For A, add (-2)(row 2) to row 1 and multiply row 2 by $\frac{1}{2}$. This yields RREF$(A) = \begin{bmatrix} 1 & 3 & 0 & -16 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{bmatrix}$. For B, exchange rows 2 and 3 to get $\begin{bmatrix} 1 & 3 & 4 & -8 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 4 \end{bmatrix}$, which is in REF. Then add 2(row 3) to row 1 to get a new matrix. In this new matrix, add (-4)(row 2) to row 1, and multiply row 3 by $\frac{1}{4}$. This yields RREF$(B) = \begin{bmatrix} 1 & 3 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$.

Observe that rank $(A) = 2$ and rank $(B) = 3$.

3. Apply Gauss–Jordan Elimination to $A = \begin{bmatrix} 2 & 6 & 4 & 4 \\ -4 & -12 & -8 & -7 \\ 0 & 0 & -1 & -4 \\ 1 & 3 & 1 & -2 \end{bmatrix}$.

Step 1. Let $U^{(1)} = A$ and $r = 1$.
Step 2. No row exchange is needed since $a_{11} \neq 0$.

Step 3. Add (2)(row 1) to row 2, and $(-\frac{1}{2})$(row 1) to row 4 to get $U^{(2)} = \begin{bmatrix} 2 & 6 & 4 & 4 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & -1 & -4 \end{bmatrix}$.

Step 4. The submatrix in rows 2, 3, 4 is not zero, so let $r = 2$ and return to Step 2.
Step 2. Search the submatrix in rows 2 to 4 of $U^{(2)}$ to see that its first nonzero column is column 3 and the first nonzero entry in this column is in row 3 of $U^{(2)}$. Exchange rows 2 and 3 in $U^{(2)}$ to get $U^{(3)} = \begin{bmatrix} 2 & 6 & 4 & 4 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & -4 \end{bmatrix}$.

Step 3. Add row 2 to row 4 in $U^{(3)}$ to get $U^{(4)} = \begin{bmatrix} 2 & 6 & 4 & 4 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$.

Step 4. Now $U^{(4)}$ is in REF, so Gaussian Elimination is finished.
Step 5. The pivot positions are $(1, 1)$, $(2, 3)$, and $(3, 4)$. Add –4(row 3) to rows 1 and 2 of $U^{(4)}$ to get $U^{(5)} = \begin{bmatrix} 2 & 6 & 4 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$. Add –4(row 2) of $U^{(5)}$ to row 1 of $U^{(5)}$ to get $U^{(6)} = \begin{bmatrix} 2 & 6 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$.

Step 6. Multiply row 1 of $U^{(6)}$ by $\frac{1}{2}$, obtaining $U^{(7)} = \begin{bmatrix} 1 & 3 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$, which is RREF$(A)$.

1.4 Systems of Linear Equations

Definitions:

A **linear equation** is an equation of the form $a_1x_1 + \cdots + a_px_p = b$ where $a_1, \ldots, a_p, b \in F$ and $x_1, \ldots, x_p$ are **variables**. The scalars a_j are **coefficients** and the scalar b is the **constant term**.

A **system of linear equations**, or **linear system**, is a set of one or more linear equations in the same variables, such as $\begin{array}{l} a_{11}x_1 + \cdots + a_{1p}x_p = b_1 \\ a_{21}x_2 + \cdots + a_{2p}x_p = b_2 \\ \cdots \\ a_{m1}x_1 + \cdots + a_{mp}x_p = b_m \end{array}$. A **solution** of the system is a p-tuple $(c_1, \ldots, c_p)$ such that letting $x_j = c_j$ for each j satisfies every equation. The **solution set** of the system is the set of all solutions. A system is **consistent** if there exists at least one solution; otherwise, it is **inconsistent**. Systems are **equivalent** if they have the same solution set. If $b_j = 0$ for all j, the system is **homogeneous**. A formula that describes a general vector in the solution set is called the **general solution**.

For the system $\begin{array}{l} a_{11}x_1 + \cdots + a_{1p}x_p = b_1 \\ a_{21}x_2 + \cdots + a_{2p}x_p = b_2 \\ \cdots \\ a_{m1}x_1 + \cdots + a_{mp}x_p = b_m \end{array}$, the $m \times p$ matrix $A = \begin{bmatrix} a_{11} & \cdots & a_{1p} \\ \vdots & \cdots & \vdots \\ a_{m1} & \cdots & a_{mp} \end{bmatrix}$ is the **coefficient matrix**, $\mathbf{b} = \begin{bmatrix} b_1 \\ \vdots \\ b_m \end{bmatrix}$ is the **constant vector**, and $\mathbf{x} = \begin{bmatrix} x_1 \\ \vdots \\ x_p \end{bmatrix}$ is the **unknown vector**.

The $m \times (p+1)$ matrix $[A\ \mathbf{b}]$ is the **augmented matrix** of the system. It is customary to identify the system of linear equations with the matrix-vector equation $A\mathbf{x} = \mathbf{b}$. This is valid because a column vector $\mathbf{x} = \begin{bmatrix} c_1 \\ \vdots \\ c_p \end{bmatrix}$ satisfies $A\mathbf{x} = \mathbf{b}$ if and only if $(c_1, \ldots, c_p)$ is a solution of the linear system.

Observe that the coefficients of x_k are stored in column k of A. If $A\mathbf{x} = \mathbf{b}$ is equivalent to $C\mathbf{x} = \mathbf{d}$ and column k of C is a pivot column, then x_k is a **basic variable**; otherwise, x_k is a **free variable**.

Facts:

Let $A\mathbf{x} = \mathbf{b}$ be a linear system, where A is an $m \times p$ matrix.

1. [SIF08, p. 33] If elementary row operations are done to the augmented matrix $[A\ \mathbf{b}]$, obtaining a new matrix $[C\ \mathbf{d}]$, the new system $C\mathbf{x} = \mathbf{d}$ is equivalent to $A\mathbf{x} = \mathbf{b}$.
2. [SIF08, p. 29] There are three possibilities for the solution set of $A\mathbf{x} = \mathbf{b}$: there are no solutions or there is exactly one solution or there is more than one solution. If there is more than one solution and F is infinite (such as the real numbers or complex numbers), then there are infinitely many solutions. If there is more than one solution and F is finite, then there are at least $|F|$ solutions.
3. A homogeneous system is always consistent (the zero vector $\mathbf{0}$ is always a solution).
4. [SIF08, p. 232] The set of solutions to the homogeneous system $A\mathbf{x} = \mathbf{0}$ is a subspace of the vector space F^p.
5. [SIF08, pp. 48, 50] The system $A\mathbf{x} = \mathbf{b}$ is consistent if and only if $\mathbf{b}$ is not a pivot column of $[A\ \mathbf{b}]$, that is, if and only if $\operatorname{rank}([A\ \mathbf{b}]) = \operatorname{rank} A$.
6. [SIF08, pp. 34–36] Suppose $A\mathbf{x} = \mathbf{b}$ is consistent. It has a unique solution if and only there is a pivot position in each column of A, that is, if and only if there are no free variables in the equation $A\mathbf{x} = \mathbf{b}$. Suppose there are $t \geq 1$ nonpivot columns in A. Then there are t free variables in the system. If $\mathrm{RREF}([A\ \mathbf{b}]) = [C\ \mathbf{d}]$, then the general solution of $C\mathbf{x} = \mathbf{d}$, hence of $A\mathbf{x} = \mathbf{b}$, can be written in the form $\mathbf{x} = s_1\mathbf{v}_1 + \cdots + s_t\mathbf{v}_t + \mathbf{w}$ where $\mathbf{v}_1, \ldots, \mathbf{v}_t$, $\mathbf{w}$ are column vectors and $s_1, \ldots, s_t$ are parameters, each representing one of the free variables. Thus, $\mathbf{x} = \mathbf{w}$ is one solution of $A\mathbf{x} = \mathbf{b}$. Also, the general solution of $A\mathbf{x} = \mathbf{0}$ is $\mathbf{x} = s_1\mathbf{v}_1 + \cdots + s_t\mathbf{v}_t$.

7. [SIF08, pp. 37–38] (General solution of a linear system algorithm)

Algorithm 2: General Solution of a Linear System $A\mathbf{x} = \mathbf{b}$

This algorithm is intended for small systems using rational arithmetic. It is not the most efficient and when some pivots are relatively small, using this algorithm in floating point arithmetic can yield inaccurate results. (For more accurate and efficient algorithms, see Chapter 51.) Let $A \in F^{m\times p}$ and $\mathbf{b} \in F^{p\times 1}$.

1. Calculate RREF($[A\ \mathbf{b}]$), obtaining $[C\ \mathbf{d}]$.
2. If there is a pivot in the last column of $[C\ \mathbf{d}]$, stop. There is no solution.
3. Assume the last column of $[C\ \mathbf{d}]$ is not a pivot column, and let $\mathbf{d} = [d_1, \dots, d_m]^T$.
   a. If rank$(C) = p$, so there exists a pivot in each column of C, then $\mathbf{x} = \mathbf{d}$ is the unique solution of the system.
   b. Suppose rank $C = r < p$.
      i. Write the system of linear equations represented by the nonzero rows of $[C\ \mathbf{d}]$. In each equation, the first nonzero term will be a basic variable, and each basic variable appears in only one of these equations.
      ii. Solve each equation for its basic variable and substitute parameter names for the $p-r$ free variables, say $s_1, \dots, s_{p-r}$. This is the general solution of $C\mathbf{x} = \mathbf{d}$ and, thus, the general solution of $A\mathbf{x} = \mathbf{b}$.
      iii. To write the general solution in vector form, as $\mathbf{x} = s_1\mathbf{v}^{(1)} + \cdots + s_{p-r}\mathbf{v}^{(p-r)} + \mathbf{w}$, let (i, k_i) be the i^{th} pivot position of C. Define $\mathbf{w} \in F^p$ by $w_{k_i} = d_i$ for $i = 1, \dots, r$, and all other entries of $\mathbf{w}$ are 0. Let x_{u_j} be the j^{th} free variable, and define the vectors $\mathbf{v}^{(j)} \in F^p$ as follows:

         For $j = 1, \dots, p-r$,
           the u_j-entry of $\mathbf{v}^{(j)}$is 1,
           for $i = 1, \dots, r$, the k_i-entry of $\mathbf{v}^{(j)}$ is $-c_{iu_j}$,
           and all other entries of $\mathbf{v}^{(j)}$ are 0.

Examples:

1. The linear system $\begin{aligned} x_1 + x_2 &= 0 \\ -x_1 + x_2 &= 0 \end{aligned}$ has augmented matrix $\begin{bmatrix} 1 & 1 & 0 \\ -1 & 1 & 0 \end{bmatrix}$. The RREF of this is $\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$, which is the augmented matrix for the equivalent system $\begin{aligned} x_1 &= 0 \\ x_2 &= 0 \end{aligned}$. Thus, the original system has a unique solution in $\mathbb{R}^2$, (0,0). In vector form the solution is $\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$.
2. The system $\begin{aligned} x_1 + x_2 &= 2 \\ x_1 - x_2 &= 0 \end{aligned}$ has a unique solution in $\mathbb{R}^2$, (1, 1), or $\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$.
3. The system $\begin{aligned} x_1 + x_2 + x_3 &= 2 \\ x_2 + x_3 &= 2 \\ x_3 &= 0 \end{aligned}$ has a unique solution in $\mathbb{R}^3$, (0, 2, 0), or $\mathbf{x} = \begin{bmatrix} 0 \\ 2 \\ 0 \end{bmatrix}$.
4. The system $\begin{aligned} x_1 + x_2 &= 2 \\ 2x_1 + 2x_2 &= 4 \end{aligned}$ has infinitely many solutions in $\mathbb{R}^2$. The augmented matrix re-

duces to $\begin{bmatrix} 1 & 1 & 2 \\ 0 & 0 & 0 \end{bmatrix}$, so the only equation left is $x_1 + x_2 = 2$. Thus, x_1 is basic and x_2 is free. Solving for x_1 and letting $x_2 = s$ gives $x_1 = -s + 2$. Then the general solution is $\begin{matrix} x_1 = -s+2 \\ x_2 = s \end{matrix}$, or all vectors of the form $(-s+2, s)$. Letting $\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$, the vector form of the general solution is $\mathbf{x} = \begin{bmatrix} -s+2 \\ s \end{bmatrix} = s\begin{bmatrix} -1 \\ 1 \end{bmatrix} + \begin{bmatrix} 2 \\ 0 \end{bmatrix}$.

5. The system $\begin{matrix} x_1 + x_2 + x_3 + x_4 = 1 \\ x_2 + x_3 - x_4 = 3 \end{matrix}$ has infinitely many solutions in $\mathbb{R}^4$. Its augmented matrix $\begin{bmatrix} 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & -1 & 3 \end{bmatrix}$ reduces to $\begin{bmatrix} 1 & 0 & 0 & 2 & -2 \\ 0 & 1 & 1 & -1 & 3 \end{bmatrix}$. Thus, x_1 and x_2 are the basic variables, and x_3 and x_4 are free. Write each of the new equations and solve it for its basic variable to see $\begin{matrix} x_1 = -2x_4 - 2 \\ x_2 = -x_3 + x_4 + 3 \end{matrix}$. Let $x_3 = s_1$ and $x_4 = s_2$ to get the general solution $\begin{matrix} x_1 = -2s_2 - 2 \\ x_2 = -s_1 + s_2 + 3 \\ x_3 = s_1 \\ x_4 = s_2 \end{matrix}$, or $\mathbf{x} = s_1\mathbf{v}^{(1)} + s_2\mathbf{v}^{(2)} + \mathbf{w} = s_1\begin{bmatrix} 0 \\ -1 \\ 1 \\ 0 \end{bmatrix} + s_2\begin{bmatrix} -2 \\ 1 \\ 0 \\ 1 \end{bmatrix} + \begin{bmatrix} -2 \\ 3 \\ 0 \\ 0 \end{bmatrix}$.

6. These systems have no solutions: $\begin{matrix} x_1 + x_2 = 0 \\ x_1 + x_2 = 1 \end{matrix}$ and $\begin{matrix} x_1 + x_2 + x_3 = 0 \\ x_1 - x_2 - x_3 = 0 \\ x_2 + x_3 = 1 \end{matrix}$. This can be verified by inspection, or by calculating the RREF of the augmented matrix of each and observing that each has a pivot in its last column.

1.5 Matrix Inverses and Elementary Matrices

Invertibility is a strong and useful property. For example, when a linear system $A\mathbf{x} = \mathbf{b}$ has an invertible coefficient matrix A, it has a unique solution. The various characterizations of invertibility in Fact 10 below are also quite useful. Throughout this section, F will denote a field.

Definitions:

An $n \times n$ matrix A is **invertible**, or **nonsingular**, if there exists another $n \times n$ matrix B, called the **inverse** of A, such that $AB = BA = I_n$. The inverse of A is denoted A^{-1} (cf. Fact 1). If no such B exists, A is **not invertible**, or **singular**.

For an $n \times n$ matrix and a positive integer m, the m**th power** of A is $A^m = \underbrace{AA\dots A}_{m \text{ copies of } A}$. It is also convenient to define $A^0 = I_n$. If A is invertible, then $A^{-m} = (A^{-1})^m$.

An **elementary matrix** is a square matrix obtained by doing one elementary row operation to an identity matrix. Thus, there are three types:

1. A multiple of one row of I_n has been added to a different row.
2. Two different rows of I_n have been exchanged.
3. One row of I_n has been multiplied by a nonzero scalar.

Facts:

Notation: Let F be a field.

1. [SIF08, p. 122] If $A \in F^{n\times n}$ is invertible, then its inverse is unique.

2. [SIF08, p. 136] (Method to compute A^{-1}) Suppose $A \in F^{n\times n}$. Create the matrix $[A \ I_n]$ and calculate its RREF, which will be of the form $[\text{RREF}(A) \ X]$. If $\text{RREF}(A) = I_n$, then A is invertible and $X = A^{-1}$. If $\text{RREF}(A) \neq I_n$, then A is not invertible. As with the Gaussian algorithm, this method is theoretically correct, but more accurate and efficient methods for calculating inverses are used in professional computer software. (See Chapter 93.)
3. [SIF08, p. 125] If $A \in F^{n\times n}$ is invertible, then A^{-1} is invertible and $(A^{-1})^{-1} = A$.
4. [SIF08, p. 125] If $A, B \in F^{n\times n}$ are invertible, then AB is invertible and $(AB)^{-1} = B^{-1}A^{-1}$.
5. [SIF08, p. 125] If $A \in F^{n\times n}$ is invertible, then A^T is invertible and $(A^T)^{-1} = (A^{-1})^T$.
6. [SIF08, pp. 123–124] If $A \in F^{n\times n}$ is invertible, then for each $\mathbf{b} \in F^{n\times 1}$, $A\mathbf{x} = \mathbf{b}$ has a unique solution, and it is $\mathbf{x} = A^{-1}\mathbf{b}$.
7. [SIF08, p. 126] Let E be an elementary matrix obtained by doing one elementary row operation to I_n. If that same row operation is done to an $n \times p$ matrix A, the result equals EA.
8. [SIF08, p. 127] An elementary matrix is invertible and its inverse is another elementary matrix of the same type.
9. [SIF08, p. 138] (Invertible Matrix Theorem) (See Section 2.5.) When $A \in F^{n\times n}$, the following are equivalent:
   (a) A is invertible.
   (b) $\text{RREF}(A) = I_n$.
   (c) $\text{Rank}(A) = n$.
   (d) The only solution of $A\mathbf{x} = \mathbf{0}$ is $\mathbf{x} = \mathbf{0}$.
   (e) For every $\mathbf{b} \in F^{n\times 1}$, $A\mathbf{x} = \mathbf{b}$ has a unique solution.
   (f) For every $\mathbf{b} \in F^{n\times 1}$, $A\mathbf{x} = \mathbf{b}$ has a solution.
   (g) There exists $B \in F^{n\times n}$ such that $AB = I_n$.
   (h) There exists $C \in F^{n\times n}$ such that $CA = I_n$.
   (i) A^T is invertible.
   (j) There exist elementary matrices whose product equals A.
10. [SIF08, p. 143] If $A, B \in F^{n\times n}$, and $AB = I_n$ or $BA = I_n$, then $B = A^{-1}$.
11. [SIF08, p. 165] and [Lay12, p. 130] Let $A \in F^{n\times n}$ be upper (lower) triangular. Then A is invertible if and only if each diagonal entry is nonzero. If A is invertible, then A^{-1} is also upper (lower) triangular, and the diagonal entries of A^{-1} are the reciprocals of those of A. In particular, if L is a unit upper (lower) triangular matrix, then L^{-1} is also a unit upper (lower) triangular matrix.
12. [SIF08, p. 101] Matrix powers obey the usual rules of exponents, i.e., when A^s and A^t are defined for integers s and t, then $A^sA^t = A^{s+t}, (A^s)^t = A^{st}$.

Examples:

1. For any n, the identity matrix I_n is invertible and is its own inverse. If P is a permutation matrix, it is invertible and $P^{-1} = P^T$.
2. If $A = \begin{bmatrix} 7 & 3 \\ 2 & 1 \end{bmatrix}$ and $B = \begin{bmatrix} 1 & -3 \\ -2 & 7 \end{bmatrix}$, then calculation shows $AB = BA = I_2$, so A is invertible and $A^{-1} = B$.
3. If $A = \begin{bmatrix} 0.2 & 4 & 1 \\ 0 & 2 & 1 \\ 0 & 0 & -1 \end{bmatrix}$, then $A^{-1} = \begin{bmatrix} 5 & -10 & -5 \\ 0 & 0.5 & 0.5 \\ 0 & 0 & -1 \end{bmatrix}$, as can be verified by multiplication.

4. The matrix $A = \begin{bmatrix} 1 & 2 \\ 2 & 4 \end{bmatrix}$ is not invertible since $\mathrm{RREF}(A) \neq I_2$. Alternatively, if B is any 2×2 matrix, AB is of the form $\begin{bmatrix} r & s \\ 2r & 2s \end{bmatrix}$, which cannot equal I_2.
5. Let A be an $n \times n$ matrix with a zero row (zero column). Then A is not invertible since $\mathrm{RREF}(A) \neq I_n$. Alternatively, if B is any $n \times n$ matrix, AB has a zero row (BA has a zero column), so B is not an inverse for A.
6. If $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ is any 2×2 matrix, then A is invertible if and only if $ad - bc \neq 0$; further, when $ad - bc \neq 0$, $A^{-1} = \dfrac{1}{ad - bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$. The scalar $ad - bc$ is called the determinant of A. (The determinant is defined for any $n \times n$ matrix in Section 4.1.) Using this formula, the matrix $A = \begin{bmatrix} 7 & 3 \\ 2 & 1 \end{bmatrix}$ from Example 2 (above) has determinant 1, so A is invertible and $A^{-1} = \begin{bmatrix} 1 & -3 \\ -2 & 7 \end{bmatrix}$, as noted above. The matrix $\begin{bmatrix} 1 & 2 \\ 2 & 4 \end{bmatrix}$ from Example 3 (above) is not invertible since its determinant is 0.
7. Let $A = \begin{bmatrix} 1 & 3 & 0 \\ 2 & 7 & 0 \\ 1 & 1 & 1 \end{bmatrix}$. Then $\mathrm{RREF}([A \quad I_n]) = \begin{bmatrix} 1 & 0 & 0 & 7 & -3 & 0 \\ 0 & 1 & 0 & -2 & 1 & 0 \\ 0 & 0 & 1 & -5 & 2 & 1 \end{bmatrix}$, so A^{-1} exists and equals $\begin{bmatrix} 7 & -3 & 0 \\ -2 & 1 & 0 \\ -5 & 2 & 1 \end{bmatrix}$.

1.6 LU Factorization

This section discusses the LU and PLU factorizations of a matrix that arise naturally when Gaussian Elimination is done. Several other factorizations are widely used for real and complex matrices, such as the QR, Singular Value, and Cholesky Factorizations (see Chapter 5 and Chapter 51). Throughout this section, F will denote a field and A will denote a matrix over F. The material in this section and additional background can be found in Sections 51.2 and 51.3 or [GV96, Chapter 4].

Definitions:

Let A be a matrix of any shape.

An LU **factorization**, or **triangular factorization**, of A is a factorization $A = LU$ where L is a square unit lower triangular matrix and U is upper triangular.

A PLU **factorization** of A is a factorization of the form $PA = LU$ where P is a permutation matrix, L is square unit lower triangular, and U is upper triangular.

An LDU **factorization** of A is a factorization $A = LDU$ where L is a square unit lower triangular matrix, D is a square diagonal matrix, and U is a unit upper triangular matrix.

A $PLDU$ **factorization** of A is a factorization $PA = LDU$ where P is a permutation matrix, L is a square unit lower triangular matrix, D is a square diagonal matrix, and U is a unit upper triangular matrix.

Facts:

1. [GV96, p. 56] Let A be square. If each leading principal submatrix of A, except possibly A itself, is invertible, then A has an LU factorization. When A is invertible,

A has an LU factorization if and only if each leading principal submatrix of A is invertible; in this case, the LU factorization is unique and there is also a unique LDU factorization of A.

2. [GV96, p. 68] Any matrix A has a PLU factorization. Algorithm 1.3.1 performs the addition of multiples of pivot rows to lower rows and perhaps row exchanges to obtain an REF matrix U. If, instead, the same series of row exchanges is done to A before any pivoting, this creates PA where P is a permutation matrix, and then PA can be reduced to U without row exchanges. That is, there exist unit lower triangular matrices E_j such that $E_k \dots E_1(PA) = U$. It follows that $PA = LU$, where $L = (E_k \dots E_1)^{-1}$ is unit lower triangular and U is upper triangular.
3. In most professional software packages, the standard method for solving a square linear system $A\mathbf{x} = \mathbf{b}$, for which A is invertible, is to reduce A to an REF matrix U as in Fact 2 above, choosing row exchanges by a strategy to reduce the magnitude of pivots, usually partial pivoting [GV96, p. 68]. By keeping track of the exchanges and pivot operations done, this produces a PLU factorization of A. Then $A = P^T LU$ and $LU\mathbf{x} = P\mathbf{b}$ is the equation to be solved. Using forward substitution, $L\mathbf{y} = P\mathbf{b}$ can be solved quickly for $\mathbf{y}$, and then $U\mathbf{x} = \mathbf{y}$ can either be solved quickly for $\mathbf{x}$ by back substitutution, or be seen to be inconsistent. This method gives accurate results for most problems. There are other types of solution methods that can work more accurately or efficiently for special types of matrices. (See Chapters 51, 53, 62, and 64.)

Examples:

1. Calculate a PLU factorization for $A = \begin{bmatrix} 1 & 1 & 2 & 3 \\ -1 & -1 & -3 & 1 \\ 0 & 1 & 1 & 1 \\ -1 & 0 & -1 & 1 \end{bmatrix}$. If Gaussian Elimination is performed on A, after adding row 1 to rows 2 and 4, rows 2 and 3 must be exchanged and the final result is $U = E_3PE_2E_1A = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & -1 & 4 \\ 0 & 0 & 0 & 3 \end{bmatrix}$ where E_1, E_2, and E_3 are lower triangular unit matrices and P is a permutation matrix. This will not yield an LU factorization of A. But if the row exchange is done to A first, by multiplying A by $P = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$, one gets $PA = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ -1 & -1 & -3 & 1 \\ -1 & 0 & -1 & 1 \end{bmatrix}$; then Gaussian Elimination can proceed without any row exchanges. Add row 1 to rows 3 and 4 to get $F_2F_1PA = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & -1 & 4 \\ 0 & 1 & 1 & 4 \end{bmatrix}$ where $F_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$ and $F_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{bmatrix}$. Then add (-1)(row 2) to row 4 to get

$U = F_3\,F_2\,F_1\,PA = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & -1 & 4 \\ 0 & 0 & 0 & 3 \end{bmatrix}$, where $F_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{bmatrix}$. Note that U is the same upper triangular matrix as before. Finally, $L = (F_3\,F_2\,F_1)^{-1}$ is unit lower triangular and $PA = LU$ is true, so this is a PLU factorization of A. To get a $PLDU$ factorization, use the same P and L, and use the diagonal entries of U to define $D = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 3 \end{bmatrix}$. Then $D^{-1}U$ is unit upper triangular; rename it $U = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & -4 \\ 0 & 0 & 0 & 1 \end{bmatrix}$.

2. Let $A = LU = \begin{bmatrix} 1 & 3 & 4 \\ -1 & -1 & -5 \\ 2 & 12 & 3 \end{bmatrix}$. Each leading principal submatrix of A is invertible so A has both LU and LDU factorizations: $A = LU = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 2 & 3 & 1 \end{bmatrix}\begin{bmatrix} 1 & 3 & 4 \\ 0 & 2 & -1 \\ 0 & 0 & -2 \end{bmatrix}$. This yields an LDU factorization of A, $\begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 2 & 3 & 1 \end{bmatrix}\begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & -2 \end{bmatrix}\begin{bmatrix} 1 & 3 & 4 \\ 0 & 1 & -0.5 \\ 0 & 0 & 1 \end{bmatrix}$. With the LU factorization, an equation such as $A\mathbf{x} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$ can be solved efficiently as follows. Use forward substitution to solve $L\mathbf{y} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$, getting $\mathbf{y} = \begin{bmatrix} 1 \\ 2 \\ -8 \end{bmatrix}$, and then backward substitution to solve $U\mathbf{x} = \mathbf{y}$, getting $\mathbf{x} = \begin{bmatrix} -24 \\ 3 \\ 4 \end{bmatrix}$.

3. Any invertible matrix whose $(1, 1)$ entry is zero, such as $\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ or $\begin{bmatrix} 0 & -1 & 5 \\ 1 & 1 & 1 \\ 1 & 0 & 3 \end{bmatrix}$, does not have an LU factorization.

4. The matrix $A = \begin{bmatrix} 1 & 3 & 4 \\ -1 & -3 & -5 \\ 2 & 6 & 6 \end{bmatrix}$ is not invertible, nor is its leading principal 2×2 submatrix, but it does have an LU factorization: $A = LU = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 2 & 3 & 1 \end{bmatrix}\begin{bmatrix} 1 & 3 & 4 \\ 0 & 0 & -1 \\ 0 & 0 & 1 \end{bmatrix}$. To find out if an equation such as $A\mathbf{x} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$ is consistent, notice $L\mathbf{y} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$ yields $\mathbf{y} = \begin{bmatrix} 1 \\ 2 \\ -8 \end{bmatrix}$, but $U\mathbf{x}$

$= \mathbf{y}$ is inconsistent, hence $A\mathbf{x} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$ has no solution.

5. The matrix $A = \begin{bmatrix} 0 & -1 & 5 \\ 1 & 1 & 1 \\ 1 & 0 & 2 \end{bmatrix}$ has no LU factorization, but does have a PLU factorization with $P = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$, $L = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix}$, and $U = \begin{bmatrix} 1 & 1 & 1 \\ 0 & -1 & 5 \\ 0 & 0 & -4 \end{bmatrix}$.

2.1 Span and Linear Independence

Let V be a vector space over a field F.

Definitions:

A **linear combination** of the vectors $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k \in V$ is a sum of scalar multiples of these vectors; that is, $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \cdots + c_k\mathbf{v}_k$, for some scalar coefficients $c_1, c_2, \ldots, c_k \in F$. If S is a set of vectors in V, a linear combination of vectors in S is a vector of the form $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \cdots + c_k\mathbf{v}_k$ with $k \in \mathbb{N}, \mathbf{v}_i \in S, c_i \in F$. Note that S may be finite or infinite, but a linear combination is, by definition, a finite sum. The zero vector is defined to be a linear combination of the empty set.

When all the scalar coefficients in a linear combination are 0, it is a **trivial linear combination.** A sum over the empty set is also a trivial linear combination.

The **span** of the vectors $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k \in V$ is the set of all linear combinations of these vectors, denoted by $\text{Span}(\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k)$. If S is a (finite or infinite) set of vectors in V, then the span of S, denoted by $\text{Span}(S)$, is the set of all linear combinations of vectors in S.

If $V = \text{Span}(S)$, then S **spans** the vector space V.

A (finite or infinite) set of vectors S in V is **linearly independent** if the only linear combination of distinct vectors in S that produces the zero vector is a trivial linear combination. That is, if $\mathbf{v}_i$ are distinct vectors in S and $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \cdots + c_k\mathbf{v}_k = \mathbf{0}$, then $c_1 = c_2 = \cdots = c_k = 0$.

Vectors that are not linearly independent are **linearly dependent**. That is, there exist distinct vectors $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k \in S$ and $c_1, c_2, \ldots, c_k$ not all 0 such that $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \cdots + c_k\mathbf{v}_k = \mathbf{0}$.

Facts: The following facts can be found in [Lay03, Sects. 4.1 and 4.3].

1. $\text{Span}(\emptyset) = \{\mathbf{0}\}$.
2. A linear combination of a single vector $\mathbf{v}$ is simply a scalar multiple of $\mathbf{v}$.

3. In a vector space V, $\text{Span}(\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k)$ is a subspace of V.
4. Suppose the set of vectors $S = \{\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k\}$ spans the vector space V. If one of the vectors, say $\mathbf{v}_i$, is a linear combination of the remaining vectors, then the set formed from S by removing $\mathbf{v}_i$ still spans V.
5. Any single nonzero vector is linearly independent.
6. Two nonzero vectors are linearly independent if and only if neither is a scalar multiple of the other.
7. If S spans V and $S \subseteq T$, then T spans V.
8. If T is a linearly independent subset of V and $S \subseteq T$, then S is linearly independent.
9. Vectors $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k$ are linearly dependent if and only if $\mathbf{v}_i = c_1\mathbf{v}_1 + \cdots + c_{i-1}\mathbf{v}_{i-1} + c_{i+1}\mathbf{v}_{i+1} + \cdots + c_k\mathbf{v}_k$, for some $1 \leq i \leq k$ and some scalars $c_1, \ldots, c_{i-1}, c_{i+1}, \ldots, c_k$. A set S of vectors in V is linearly dependent if and only if there exists $\mathbf{v} \in S$ such that $\mathbf{v}$ is a linear combination of other vectors in S.
10. Any set of vectors that includes the zero vector is linearly dependent.

Examples:

1. Linear combinations of $\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix} \in \mathbb{R}^2$ are vectors of the form $c_1 \begin{bmatrix} 1 \\ -1 \end{bmatrix} + c_2 \begin{bmatrix} 0 \\ 3 \end{bmatrix} = \begin{bmatrix} c_1 \\ -c_1 + 3c_2 \end{bmatrix}$, for any scalars $c_1, c_2 \in \mathbb{R}$. Any vector of this form is in $\text{Span}\left(\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix}\right)$. In fact, $\text{Span}\left(\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix}\right) = \mathbb{R}^2$ and these vectors are linearly independent.
2. If $\mathbf{v} \in \mathbb{R}^n$ and $\mathbf{v} \neq \mathbf{0}$, then geometrically $\text{Span}(\mathbf{v})$ is a line in $\mathbb{R}^n$ through the origin.
3. Suppose $n \geq 2$ and $\mathbf{v}_1, \mathbf{v}_2 \in \mathbb{R}^n$ are linearly independent vectors. Then geometrically $\text{Span}(\mathbf{v}_1, \mathbf{v}_2)$ is a plane in $\mathbb{R}^n$ through the origin.
4. Any polynomial $p(x) \in \mathbb{R}[x]$ of degree less than or equal to 2 can easily be seen to be a linear combination of 1, x, and x^2. However, $p(x)$ is also a linear combination of $1, 1+x$, and $1+x^2$. So $\text{Span}(1, x, x^2) = \text{Span}(1, 1+x, 1+x^2) = \mathbb{R}[x; 2]$.
5. The n vectors $\mathbf{e}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \mathbf{e}_2 = \begin{bmatrix} 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \ldots, \mathbf{e}_n = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}$ span F^n, for any field F. These vectors are also linearly independent.
6. In $\mathbb{R}^2$, $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$ and $\begin{bmatrix} 0 \\ 3 \end{bmatrix}$ are linearly independent. However, $\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix}$, and $\begin{bmatrix} 1 \\ 5 \end{bmatrix}$ are linearly dependent because $\begin{bmatrix} 1 \\ 5 \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \end{bmatrix} + 2\begin{bmatrix} 0 \\ 3 \end{bmatrix}$.
7. The infinite set $\{1, x, x^2, \ldots, x^n, \ldots\}$ is linearly independent in $F[x]$, for any field F.
8. In the vector space of continuous real-valued functions on the real line, $\mathcal{C}(\mathbb{R})$, the set $\{\sin(x), \sin(2x), \ldots, \sin(nx), \cos(x), \cos(2x), \ldots, \cos(nx)\}$ is linearly independent for any $n \in \mathbb{N}$. The infinite set $\{\sin(x), \sin(2x), \ldots, \sin(nx), \ldots, \cos(x), \cos(2x), \ldots, \cos(nx), \ldots\}$ is also linearly independent in $\mathcal{C}(\mathbb{R})$.

Applications:

1. The linear homogeneous differential equation $\frac{d^2y}{dx^2} - 3\frac{dy}{dx} + 2y = 0$ has as solutions $y_1(x) = e^{2x}$ and $y_2(x) = e^x$. Any linear combination $y(x) = c_1y_1(x) + c_2y_2(x)$ is a solution of the differential equation, and so $\text{Span}(e^{2x}, e^x)$ is contained in the set of solutions of the differential equation (called the solution space for the differential equation). In fact, the solution space is spanned by e^{2x} and e^x, and so is a subspace of the vector space of functions. In general, the solution space for a linear homogeneous differential equation is a vector space, meaning that any linear combination of solutions is again a solution.

2.2 Basis and Dimension of a Vector Space

Let V be a vector space over a field F.

Definitions:

A set of vectors $\mathcal{B}$ in a vector space V is a **basis** for V if

- $\mathcal{B}$ is a linearly independent set, and
- $\text{Span}(\mathcal{B}) = V$.

The set $\mathcal{E}_n = \left\{ \mathbf{e}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \mathbf{e}_2 = \begin{bmatrix} 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \dots, \mathbf{e}_n = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix} \right\}$ is the **standard basis** for F^n.

The number of vectors in a basis for a vector space V is the **dimension** of V, denoted by $\dim(V)$. If a basis for V contains a finite number of vectors, then V is **finite dimensional**. Otherwise, V is **infinite dimensional**, and we write $\dim(V) = \infty$.

Facts: All the following facts, except those with a specific reference, can be found in [Lay03, Sects. 4.3 and 4.5].

1. Every vector space has a basis.
2. The standard basis for F^n is a basis for F^n, and so $\dim F^n = n$.
3. A basis $\mathcal{B}$ in a vector space V is the largest set of linearly independent vectors in V that contains $\mathcal{B}$, and it is the smallest set of vectors in V that contains $\mathcal{B}$ and spans V.
4. The empty set is a basis for the trivial vector space $\{\mathbf{0}\}$, and $\dim(\{\mathbf{0}\}) = 0$.
5. If the set $S = \{\mathbf{v}_1, \dots, \mathbf{v}_p\}$ spans a vector space V, then some subset of S forms a basis for V. In particular, if one of the vectors, say $\mathbf{v}_i$, is a linear combination of the remaining vectors, then the set formed from S by removing $\mathbf{v}_i$ will be "closer" to a basis for V. This process can be continued until the remaining vectors form a basis for V.
6. If S is a linearly independent set in a vector space V, then S can be expanded, if necessary, to a basis for V.
7. No nontrivial vector space over a field with more than two elements has a unique basis.
8. If a vector space V has a basis containing n vectors, then every basis of V must contain n vectors. Similarly, if V has an infinite basis, then every basis of V must be infinite. So, the dimension of V is unique.
9. Let $\dim(V) = n$ and let S be a set containing n vectors. The following are equivalent:

   (a) S is a basis for V.
   (b) S spans V.
   (c) S is linearly independent.

10. If $\dim(V) = n$, then any subset of V containing more than n vectors is linearly dependent.
11. If $\dim(V) = n$, then any subset of V containing fewer than n vectors does not span V.
12. [Lay03, Sect. 4.4] If $\mathcal{B} = \{\mathbf{b}_1, \ldots, \mathbf{b}_p\}$ is a basis for a vector space V, then each $\mathbf{x} \in V$ can be expressed as a unique linear combination of the vectors in $\mathcal{B}$. That is, for each $\mathbf{x} \in V$ there is a unique set of scalars $c_1, c_2, \ldots, c_p$ such that $\mathbf{x} = c_1\mathbf{b}_1 + c_2\mathbf{b}_2 + \cdots + c_p\mathbf{b}_p$.

Examples:

1. In $\mathbb{R}^2$, $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$ and $\begin{bmatrix} 0 \\ 3 \end{bmatrix}$ are linearly independent, and they span $\mathbb{R}^2$. So, they form a basis for $\mathbb{R}^2$ and $\dim(\mathbb{R}^2) = 2$.
2. In $F[x]$, the set $\{1, x, x^2, \ldots, x^n\}$ is a basis for $F[x; n]$ for any $n \in \mathbb{N}$. The infinite set $\{1, x, x^2, x^3, \ldots\}$ is a basis for $F[x]$, meaning $\dim(F[x]) = \infty$.
3. The set of $m \times n$ matrices E_{ij} having a 1 in the i, j-entry and zeros everywhere else forms a basis for $F^{m\times n}$. Since there are mn such matrices, $\dim(F^{m\times n}) = mn$.
4. The set $S = \left\{ \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 2 \end{bmatrix} \right\}$ clearly spans $\mathbb{R}^2$, but it is not a linearly independent set. However, removing any single vector from S will cause the remaining vectors to be a basis for $\mathbb{R}^2$ because any pair of vectors is linearly independent and still spans $\mathbb{R}^2$.
5. The set $S = \left\{ \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \\ 1 \\ 1 \end{bmatrix} \right\}$ is linearly independent, but it cannot be a basis for $\mathbb{R}^4$ since it does not span $\mathbb{R}^4$. However, we can start expanding it to a basis for $\mathbb{R}^4$ by first adding a vector that is not in the span of S, such as $\begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$. Then since these three vectors still do not span $\mathbb{R}^4$, we can add a vector that is not in their span, such as $\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}$. These four vectors now span $\mathbb{R}^4$ and they are linearly independent, so they form a basis for $\mathbb{R}^4$.
6. Additional techniques for determining whether a given finite set of vectors is linearly independent or spans a given subspace can be found in Sections 2.5 and 2.6.

Applications:

1. Because $y_1(x) = e^{2x}$ and $y_2(x) = e^x$ are linearly independent and span the solution space for the homogeneous differential equation $\frac{d^2y}{dx^2} - 3\frac{dy}{dx} + 2y = 0$, they form a basis for the solution space and the solution space has dimension 2.

2.3 Direct Sum Decompositions

Throughout this section, V will be a vector space over a field F, and W_i, for $i = 1, \ldots, k$, will be subspaces of V. For facts and general reading for this section, see [HK71].

Definitions:

The **sum** of subspaces W_i, for $i = 1, \ldots, k$, is $\sum_{i=1}^{k} W_i = W_1 + \cdots + W_k = \{\mathbf{w}_1 + \cdots + \mathbf{w}_k \mid \mathbf{w}_i \in W_i\}$.

The sum $W_1 + \cdots + W_k$ is a **direct sum** if for all $i = 1, \ldots, k$, we have $W_i \cap \sum_{j \neq i} W_j = \{\mathbf{0}\}$. $W = W_1 \oplus \cdots \oplus W_k$ denotes that $W = W_1 + \cdots + W_k$ and the sum is direct.

The subspaces W_i, for $i = i, \ldots, k$, are **independent** if for $\mathbf{w}_i \in W_i$, $\mathbf{w}_1 + \cdots + \mathbf{w}_k = \mathbf{0}$ implies $\mathbf{w}_i = \mathbf{0}$ for all $i = 1, \ldots, k$.

Let V_i, for $i = 1, \ldots, k$, be vector spaces over F. The **external direct sum** of the V_i, denoted $V_1 \times \cdots \times V_k$, is the cartesian product of V_i, for $i = 1, \ldots, k$, with coordinate-wise operations.

Let W be a subspace of V. An **additive coset** of W is a subset of the form $v + W = \{v + w \mid w \in W\}$ with $v \in V$.

The **quotient** of V by W, denoted V/W, is the set of additive cosets of W with operations $(v_1 + W) + (v_2 + W) = (v_1 + v_2) + W$ and $c(v + W) = (cv) + W$, for any $c \in F$.

Let $V = W \oplus U$, let $\mathcal{B}_W$ and $\mathcal{B}_U$ be bases for W and U, respectively, and let $\mathcal{B} = \mathcal{B}_W \cup \mathcal{B}_U$. The **induced basis** of $\mathcal{B}$ in V/W is the set of vectors $\{u + W \mid u \in \mathcal{B}_U\}$.

Facts:

1. $W = W_1 \oplus W_2$ if and only if $W = W_1 + W_2$ and $W_1 \cap W_2 = \{\mathbf{0}\}$.
2. If W is a subspace of V, then there exists a subspace U of V such that $V = W \oplus U$. Note that U is not usually unique.
3. Let $W = W_1 + \cdots + W_k$. The following are equivalent:
    (a) $W = W_1 \oplus \cdots \oplus W_k$. That is, for all $i = 1, \ldots, k$, we have $W_i \cap \sum_{j \neq i} W_j = \{\mathbf{0}\}$.
    (b) $W_i \cap \sum_{j=1}^{i-1} W_j = \{\mathbf{0}\}$, for all $i = 2, \ldots, k$.
    (c) For each $\mathbf{w} \in W$, $\mathbf{w}$ can be expressed in exactly one way as a sum of vectors in $W_1, \ldots, W_k$. That is, there exist unique $\mathbf{w}_i \in W_i$, such that $\mathbf{w} = \mathbf{w}_1 + \cdots + \mathbf{w}_k$.
    (d) The subspaces W_i, for $i = 1, \ldots, k$, are independent.
    (e) If $\mathcal{B}_i$ is an (ordered) basis for W_i, then $\mathcal{B} = \bigcup_{i=1}^{k} \mathcal{B}_i$ is an (ordered) basis for W.
4. If $\mathcal{B}$ is a basis for V and $\mathcal{B}$ is partitioned into disjoint subsets $\mathcal{B}_i$, for $i = 1, \ldots, k$, then $V = \operatorname{Span}(\mathcal{B}_1) \oplus \cdots \oplus \operatorname{Span}(\mathcal{B}_k)$.
5. If S is a linearly independent subset of V and S is partitioned into disjoint subsets S_i, for $i = 1, \ldots, k$, then the subspaces $\operatorname{Span}(S_1), \ldots, \operatorname{Span}(S_k)$ are independent.
6. If V is finite dimensional and $V = W_1 + \cdots + W_k$, then $\dim(V) = \dim(W_1) + \cdots + \dim(W_k)$ if and only if $V = W_1 \oplus \cdots \oplus W_k$.
7. Let V_i, for $i = 1, \ldots, k$, be vector spaces over F.
    (a) $V_1 \times \cdots \times V_k$ is a vector space over F.
    (b) $\widehat{V_i} = \{(0, \ldots, 0, v_i, 0, \ldots, 0) \mid v_i \in V_i\}$ (where v_i is the ith coordinate) is a subspace of $V_1 \times \cdots \times V_k$.
    (c) $V_1 \times \cdots \times V_k = \widehat{V_1} \oplus \cdots \oplus \widehat{V_k}$.
    (d) If V_i, for $i = 1, \ldots, k$, are finite dimensional, then $\dim \widehat{V_i} = \dim V_i$ and $\dim(V_1 \times \cdots \times V_k) = \dim V_1 + \cdots + \dim V_k$.
8. If W is a subspace of V, then the quotient V/W is a vector space over F.
9. Let $V = W \oplus U$, let $\mathcal{B}_W$ and $\mathcal{B}_U$ be bases for W and U, respectively, and let $\mathcal{B} = \mathcal{B}_W \cup \mathcal{B}_U$. The induced basis of $\mathcal{B}$ in V/W is a basis for V/W and $\dim(V/W) = \dim U$.

Examples:

1. Let $\mathcal{B} = \{\mathbf{v}_1, \ldots, \mathbf{v}_n\}$ be a basis for V. Then $V = \operatorname{Span}(\mathbf{v}_1) \oplus \cdots \oplus \operatorname{Span}(\mathbf{v}_n)$.
2. Let $X = \left\{ \begin{bmatrix} x \\ 0 \end{bmatrix} \mid x \in \mathbb{R} \right\}, Y = \left\{ \begin{bmatrix} 0 \\ y \end{bmatrix} \mid y \in \mathbb{R} \right\}$, and $Z = \left\{ \begin{bmatrix} z \\ z \end{bmatrix} \mid z \in \mathbb{R} \right\}$. Then $\mathbb{R}^2 = X \oplus Y = Y \oplus Z = X \oplus Z$.
3. In $F^{n\times n}$, let W_1 be the subspace of symmetric matrices and W_2 be the subspace of skew-symmetric matrices. Clearly, $W_1 \cap W_2 = \{\mathbf{0}\}$. For any $A \in F^{n\times n}$, $A = \dfrac{A + A^T}{2} + \dfrac{A - A^T}{2}$, where $\dfrac{A + A^T}{2} \in W_1$ and $\dfrac{A - A^T}{2} \in W_2$. Therefore, $F^{n\times n} = W_1 \oplus W_2$.
4. Recall that the function $f \in \mathcal{C}(\mathbb{R})$ is even if $f(-x) = f(x)$ for all x, and f is odd if $f(-x) = -f(x)$ for all x. Let W_1 be the subspace of even functions and W_2 be the subspace of odd functions. Clearly, $W_1 \cap W_2 = \{\mathbf{0}\}$. For any $f \in \mathcal{C}(\mathbb{R}), f = f_1 + f_2$, where $f_1(x) = \dfrac{f(x) + f(-x)}{2} \in W_1$ and $f_1(x) = \dfrac{f(x) - f(-x)}{2} \in W_2$. Therefore, $\mathcal{C}(\mathbb{R}) = W_1 \oplus W_2$.
5. Given a subspace W of V, we can find a subspace U such that $V = W \oplus U$ by choosing a basis for W, extending this linearly independent set to a basis for V, and setting U equal to the span of the basis vectors not in W. For example, in $\mathbb{R}^3$, Let $W = \left\{ \begin{bmatrix} a \\ -2a \\ a \end{bmatrix} \mid a \in \mathbb{R} \right\}$. If $\mathbf{w} = \begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix}$, then $\{\mathbf{w}\}$ is a basis for W. Extend this to a basis for $\mathbb{R}^3$, for example by adjoining $\mathbf{e}_1$ and $\mathbf{e}_2$. Thus, $V = W \oplus U$, where $U = \operatorname{Span}(\mathbf{e}_1, \mathbf{e}_2)$. Note: there are many other ways to extend the basis, and many other possible U.
6. In the external direct sum $\mathbb{R}[x;2] \times \mathbb{R}^{2\times 2}$, $\left(2x^2 + 7, \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}\right) + 3\left(x^2 + 4x - 2, \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}\right) = \left(5x^2 + 12x + 1, \begin{bmatrix} 1 & 5 \\ 0 & 4 \end{bmatrix}\right)$.
7. The subspaces X, Y, Z of $\mathbb{R}^2$ in Example 2 have bases $\mathcal{B}_X = \left\{ \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right\}, \mathcal{B}_Y = \left\{ \begin{bmatrix} 0 \\ 1 \end{bmatrix} \right\}, \mathcal{B}_Z = \left\{ \begin{bmatrix} 1 \\ 1 \end{bmatrix} \right\}$, respectively. Then $\mathcal{B}_{XY} = \mathcal{B}_X \cup \mathcal{B}_Y$ and $\mathcal{B}_{XZ} = \mathcal{B}_X \cup \mathcal{B}_Z$ are bases for $\mathbb{R}^2$. In $\mathbb{R}^2/X$, the induced bases of $\mathcal{B}_{XY}$ and $\mathcal{B}_{XZ}$ are $\left\{ \begin{bmatrix} 0 \\ 1 \end{bmatrix} + X \right\}$ and $\left\{ \begin{bmatrix} 1 \\ 1 \end{bmatrix} + X \right\}$, respectively. These are equal because $\begin{bmatrix} 1 \\ 1 \end{bmatrix} + X = \begin{bmatrix} 0 \\ 1 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} + X = \begin{bmatrix} 0 \\ 1 \end{bmatrix} + X$.

2.4 Matrix Range, Null Space, Rank, and the Dimension Theorem

Definitions:

For any matrix $A \in F^{m\times n}$, the **range** of A, denoted by range(A), is the set of all linear combinations of the columns of A. If $A = [\mathbf{m}_1\ \mathbf{m}_2\ \ldots\ \mathbf{m}_n]$, then range$(A) = \operatorname{Span}(\mathbf{m}_1, \mathbf{m}_2, \ldots, \mathbf{m}_n)$. The range of A is also called the **column space** of A.

The **row space** of A, denoted by $\text{RS}(A)$, is the set of all linear combinations of the rows of A. If $A = [\mathbf{v}_1\ \mathbf{v}_2\ \dots\ \mathbf{v}_m]^T$, then $\text{RS}(A) = \text{Span}(\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m)$.

The **kernel** of A, denoted by $\ker(A)$, is the set of all solutions to the homogeneous equation $A\mathbf{x} = \mathbf{0}$. The kernel of A is also called the **null space** of A, and its dimension is called the **nullity** of A, denoted by $\text{null}(A)$.

The **rank** of A, denoted by $\text{rank}(A)$, is the number of leading entries in the reduced row echelon form of A (or any row echelon form of A). (See Section 1.3 for more information.)

$A, B \in F^{m\times n}$ are **equivalent** if $B = C_1^{-1}AC_2$ for some invertible matrices $C_1 \in F^{m\times m}$ and $C_2 \in F^{n\times n}$. $A, B \in F^{n\times n}$ are **similar** if $B = C^{-1}AC$ for some invertible matrix $C \in F^{n\times n}$. For square matrices $A_1 \in F^{n_1\times n_1}, \dots, A_k \in F^{n_k\times n_k}$, the **matrix direct sum** $A = A_1 \oplus \cdots \oplus A_k$ is the block diagonal matrix with the matrices A_i down the diagonal. That is, $A = \begin{bmatrix} A_1 & & \mathbf{0} \\ & \ddots & \\ \mathbf{0} & & A_k \end{bmatrix}$, where $A \in F^{n\times n}$ with $n = \sum_{i=1}^{k} n_i$.

Facts: Unless specified otherwise, the following facts can be found in [Lay03, Sects. 2.8, 4.2, 4.5, and 4.6].

1. The range of an $m \times n$ matrix A is a subspace of F^m.
2. The columns of A corresponding to the pivot columns in the reduced row echelon form of A (or any row echelon form of A) give a basis for $\text{range}(A)$. Let $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k \in F^m$. If matrix $A = [\mathbf{v}_1\ \mathbf{v}_2\ \dots\ \mathbf{v}_k]$, then a basis for $\text{range}(A)$ will be a linearly independent subset of $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k$ having the same span.
3. $\dim(\text{range}(A)) = \text{rank}(A)$.
4. The kernel of an $m \times n$ matrix A is a subspace of F^n.
5. If the reduced row echelon form of A (or any row echelon form of A) has k pivot columns, then $\text{null}(A) = n - k$.
6. If two matrices A and B are row equivalent, then $\text{RS}(A) = \text{RS}(B)$.
7. The row space of an $m \times n$ matrix A is a subspace of F^n.
8. The pivot rows in the reduced row echelon form of A (or any row echelon form of A) give a basis for $\text{RS}(A)$.
9. $\dim(\text{RS}(A)) = \text{rank}(A)$.
10. $\text{rank}(A) = \text{rank}(A^T)$.
11. (Dimension Theorem) For any $A \in F^{m\times n}$, $n = \text{rank}(A) + \text{null}(A)$. Similarly, $m = \dim(\text{RS}(A)) + \text{null}(A^T)$.
12. A vector $\mathbf{b} \in F^m$ is in $\text{range}(A)$ if and only if the equation $A\mathbf{x} = \mathbf{b}$ has a solution. So $\text{range}(A) = F^m$ if and only if the equation $A\mathbf{x} = \mathbf{b}$ has a solution for every $\mathbf{b} \in F^m$.
13. A vector $\mathbf{a} \in F^n$ is in $\text{RS}(A)$ if and only if the equation $A^T\mathbf{y} = \mathbf{a}$ has a solution. So $\text{RS}(A) = F^n$ if and only if the equation $A^T\mathbf{y} = \mathbf{a}$ has a solution for every $\mathbf{a} \in F^n$.
14. If $\mathbf{a}$ is a solution to the equation $A\mathbf{x} = \mathbf{b}$, then $\mathbf{a} + \mathbf{v}$ is also a solution for any $\mathbf{v} \in \ker(A)$.
15. [HJ85, p. 14] If $A \in F^{m\times n}$ is rank 1, then there are vectors $\mathbf{v} \in F^m$ and $\mathbf{u} \in F^n$ so that $A = \mathbf{v}\mathbf{u}^T$.
16. If $A \in F^{m\times n}$ is rank k, then A is a sum of k rank 1 matrices. That is, there exist $A_1, \dots, A_k$ with $A = A_1 + \cdots + A_k$ and $\text{rank}(A_i) = 1$, for $i = 1, \dots, k$.
17. [HJ85, p. 13] The following are all equivalent statements about a matrix $A \in F^{m\times n}$.
    (a) The rank of A is k.
    (b) $\dim(\text{range}(A)) = k$.

   (c) The reduced row echelon form of A has k pivot columns.
   (d) A row echelon form of A has k pivot columns.
   (e) The largest number of linearly independent columns of A is k.
   (f) The largest number of linearly independent rows of A is k.

18. [HJ85, p. 13] (Rank Inequalities) (Unless specified otherwise, assume that $A, B \in F^{m\times n}$.)
   (a) $\operatorname{rank}(A) \leq \min(m, n)$.
   (b) If a new matrix B is created by deleting rows and/or columns of matrix A, then $\operatorname{rank}(B) \leq \operatorname{rank}(A)$.
   (c) $\operatorname{rank}(A + B) \leq \operatorname{rank}(A) + \operatorname{rank}(B)$.
   (d) If A has a $p \times q$ submatrix of 0s, then $\operatorname{rank}(A) \leq (m - p) + (n - q)$.
   (e) If $A \in F^{m\times k}$ and $B \in F^{k\times n}$, then

$$\operatorname{rank}(A) + \operatorname{rank}(B) - k \leq \operatorname{rank}(AB) \leq \min\{\operatorname{rank}(A), \operatorname{rank}(B)\}.$$

19. [HJ85, pp. 13–14] (Rank Equalities)
   (a) If $A \in \mathbb{C}^{m\times n}$, then $\operatorname{rank}(A^*) = \operatorname{rank}(A^T) = \operatorname{rank}(\overline{A}) = \operatorname{rank}(A)$.
   (b) If $A \in \mathbb{C}^{m\times n}$, then $\operatorname{rank}(A^*A) = \operatorname{rank}(A)$. If $A \in \mathbb{R}^{m\times n}$, then $\operatorname{rank}(A^TA) = \operatorname{rank}(A)$.
   (c) Rank is unchanged by left or right multiplication by a nonsingular matrix. That is, if $A \in F^{n\times n}$ and $B \in F^{m\times m}$ are nonsingular, and $M \in F^{m\times n}$, then

$$\operatorname{rank}(AM) = \operatorname{rank}(M) = \operatorname{rank}(MB) = \operatorname{rank}(AMB).$$

   (d) If $A, B \in F^{m\times n}$, then $\operatorname{rank}(A) = \operatorname{rank}(B)$ if and only if there exist nonsingular matrices $X \in F^{m\times m}$ and $Y \in F^{n\times n}$ such that $A = XBY$ (i.e., if and only if A is equivalent to B).
   (e) If $A \in F^{m\times n}$ has rank k, then $A = XBY$, for some $X \in F^{m\times k}$, $Y \in F^{k\times n}$, and nonsingular $B \in F^{k\times k}$.
   (f) If $A_1 \in F^{n_1\times n_1}, \ldots, A_k \in F^{n_k\times n_k}$, then $\operatorname{rank}(A_1 \oplus \cdots \oplus A_k) = \operatorname{rank}(A_1) + \cdots + \operatorname{rank}(A_k)$.

20. Let $A, B \in F^{n\times n}$ with A similar to B.
   (a) A is equivalent to B.
   (b) $\operatorname{rank}(A) = \operatorname{rank}(B)$.
   (c) $\operatorname{tr} A = \operatorname{tr} B$.

21. Equivalence of matrices is an equivalence relation on $F^{m\times n}$.
22. Similarity of matrices is an equivalence relation on $F^{n\times n}$.
23. For information on the determination of whether two matrices are similar, see Chapter 6.
24. If $A \in F^{m\times n}$ and $\operatorname{rank}(A) = k$, then A is equivalent to $\begin{bmatrix} I_k & 0 \\ 0 & 0 \end{bmatrix}$, and so any two matrices of the same size and rank are equivalent.
25. $A \in F^{n\times n}$ has rank k if and only if A has a nonsingular $k \times k$ submatrix, and every $(k + 1) \times (k + 1)$ submatrix of A is singular.
26. [GR01, Corollary 8.9.2] If $A \in F^{n\times n}$ is symmetric and has rank k, then A has a nonsingular $k \times k$ principal submatrix.

27. If $A \in F^{n\times n}$ is skew-symmetric and has rank k, then k is even and A has a nonsingular $k \times k$ principal submatrix.
28. [Lay03, Sect. 6.1] If $A \in \mathbb{R}^{n\times n}$, then for any $\mathbf{x} \in \mathrm{RS}(A)$ and any $\mathbf{y} \in \ker(A)$, $\mathbf{x}^T\mathbf{y} = 0$. So the row space and kernel of a real matrix are orthogonal to one another. (See Chapter 5 for more on orthogonality.)
29. (Theorem of the Alternative) Let $A \in F^{m\times n}$, $\mathbf{b} \in F^m$, and σ an automorphism of $F^{m\times n}$ of order at most 2. Then either $A\mathbf{x} = \mathbf{b}$ has a solution or there exists $\mathbf{y} \in F^m$ such that $\mathbf{y}^\sigma A = \mathbf{0}$ and $\mathbf{y}^\sigma \mathbf{b} \neq 0$.

    (a) [Gal60, p.41] When $F = \mathbb{R}$, then either $A\mathbf{x} = \mathbf{b}$ has a solution or there exists $\mathbf{y} \in \mathbb{R}^m$ such that $\mathbf{y}^T A = \mathbf{0}$ and $\mathbf{y}^T\mathbf{b} \neq 0$.

    (b) [LT85, p. 115] When $F = \mathbb{C}$, then either $A\mathbf{x} = \mathbf{b}$ has a solution or there exists $\mathbf{y} \in \mathbb{C}^m$ such that $\mathbf{y}^* A = \mathbf{0}$ and $\mathbf{y}^*\mathbf{b} \neq 0$.

Examples:

1. If $A = \begin{bmatrix} 1 & 7 & -2 \\ 0 & -1 & 1 \\ 2 & 13 & -3 \end{bmatrix} \in \mathbb{R}^{3\times 3}$, then any vector of the form $\begin{bmatrix} a+7b-2c \\ -b+c \\ 2a+13b-3c \end{bmatrix} \left(= \begin{bmatrix} 1 & 7 & -2 \\ 0 & -1 & 1 \\ 2 & 13 & -3 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix} \right)$ is in range(A), for any $a, b, c \in \mathbb{R}$. Since a row echelon form of A is $\begin{bmatrix} 1 & 7 & -2 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{bmatrix}$, we know that the set $\left\{ \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix}, \begin{bmatrix} 7 \\ -1 \\ 13 \end{bmatrix} \right\}$ is a basis for range(A), and the set $\left\{ \begin{bmatrix} 1 \\ 7 \\ -2 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ -1 \end{bmatrix} \right\}$ is a basis for RS(A). Since its reduced row echelon form is $\begin{bmatrix} 1 & 0 & 5 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{bmatrix}$, the set $\left\{ \begin{bmatrix} 1 \\ 0 \\ 5 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ -1 \end{bmatrix} \right\}$ is another basis for RS(A).
2. If $A = \begin{bmatrix} 1 & 7 & -2 \\ 0 & -1 & 1 \\ 2 & 13 & -3 \end{bmatrix} \in \mathbb{R}^{3\times 3}$, then using the reduced row echelon form given in the previous example, solutions to $A\mathbf{x} = \mathbf{0}$ have the form $\mathbf{x} = c \begin{bmatrix} -5 \\ 1 \\ 1 \end{bmatrix}$, for any $c \in \mathbb{R}$. So $\ker(A) = \mathrm{Span}\left(\begin{bmatrix} -5 \\ 1 \\ 1 \end{bmatrix} \right)$.
3. If $A \in \mathbb{R}^{3\times 5}$ has the reduced row echelon form $\begin{bmatrix} 1 & 0 & 3 & 0 & 2 \\ 0 & 1 & -2 & 0 & 7 \\ 0 & 0 & 0 & 1 & -1 \end{bmatrix}$, then any solution to

$A\mathbf{x} = \mathbf{0}$ has the form

$$\mathbf{x} = c_1 \begin{bmatrix} -3 \\ 2 \\ 1 \\ 0 \\ 0 \end{bmatrix} + c_2 \begin{bmatrix} -2 \\ -7 \\ 0 \\ 1 \\ 1 \end{bmatrix}$$

for some $c_1, c_2 \in \mathbb{R}$. So,

$$\ker(A) = \operatorname{Span}\left(\begin{bmatrix} -3 \\ 2 \\ 1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} -2 \\ -7 \\ 0 \\ 1 \\ 1 \end{bmatrix} \right).$$

4. Example 1 shows that $\left\{ \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix}, \begin{bmatrix} 7 \\ -1 \\ 13 \end{bmatrix} \right\}$ is a linearly independent set having the same span as the set $\left\{ \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix}, \begin{bmatrix} 7 \\ -1 \\ 13 \end{bmatrix}, \begin{bmatrix} -2 \\ 1 \\ -3 \end{bmatrix} \right\}$.
5. $\begin{bmatrix} 1 & 7 \\ 2 & -3 \end{bmatrix}$ is similar to $\begin{bmatrix} 37 & -46 \\ 31 & -39 \end{bmatrix}$ because $\begin{bmatrix} 37 & -46 \\ 31 & -39 \end{bmatrix} = \begin{bmatrix} -2 & 3 \\ 3 & -4 \end{bmatrix}^{-1} \begin{bmatrix} 1 & 7 \\ 2 & -3 \end{bmatrix} \begin{bmatrix} -2 & 3 \\ 3 & -4 \end{bmatrix}$.

2.5 Nonsingularity Characterizations

From the previous discussion, we can add to the list of nonsingularity characterizations of a square matrix that was started in Chapter 1.

Facts: The following facts can be found in [HJ85, p. 14] or [Lay03, Sects. 2.3 and 4.6], unless noted otherwise.

1. If $A \in F^{n\times n}$, then the following are equivalent.
   (a) A is nonsingular.
   (b) The columns of A are linearly independent.
   (c) The dimension of range(A) is n.
   (d) The range of A is F^n.
   (e) The equation $A\mathbf{x} = \mathbf{b}$ is consistent for each $\mathbf{b} \in F^n$.
   (f) If the equation $A\mathbf{x} = \mathbf{b}$ is consistent, then the solution is unique.
   (g) The equation $A\mathbf{x} = \mathbf{b}$ has a unique solution for each $\mathbf{b} \in F^n$.
   (h) The rows of A are linearly independent.
   (i) The dimension of RS(A) is n.
   (j) The row space of A is F^n.
   (k) The dimension of ker(A) is 0.
   (l) The only solution to $A\mathbf{x} = \mathbf{0}$ is $\mathbf{x} = \mathbf{0}$.
   (m) The rank of A is n.
   (n) The determinant of A is nonzero. (See Section 4.1 for the definition of the determinant.)

2.6 Coordinates and Change of Basis

Coordinates are used to transform a problem in a more abstract vector space (e.g., the vector space of polynomials of degree less than or equal to 3) to a problem in F^n.

Definitions:

Suppose that $\mathcal{B} = (\mathbf{b}_1, \mathbf{b}_2, \ldots, \mathbf{b}_n)$ is an ordered basis for a vector space V over a field F and $\mathbf{x} \in V$. The **coordinates of x relative to the ordered basis $\mathcal{B}$** (or the **$\mathcal{B}$-coordinates of x**) are the scalar coefficients $c_1, c_2, \ldots, c_n \in F$ such that $\mathbf{x} = c_1\mathbf{x}_1 + c_2\mathbf{x}_2 + \cdots + c_n\mathbf{x}_n$. Whenever coordinates are involved, the vector space is assumed to be nonzero and finite dimensional.

If $c_1, c_2, \ldots, c_n$ are the $\mathcal{B}$-coordinates of $\mathbf{x}$, then the vector in F^n,

$$[\mathbf{x}]_{\mathcal{B}} = \begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_n \end{bmatrix},$$

is the **coordinate vector of x relative to $\mathcal{B}$** or the **$\mathcal{B}$-coordinate vector of x**.

The mapping $\mathbf{x} \to [\mathbf{x}]_{\mathcal{B}}$ is the **coordinate mapping determined by $\mathcal{B}$**.

If $\mathcal{B}$ and $\mathcal{B}'$ are ordered bases for the vector space F^n, then the **change-of-basis matrix** from $\mathcal{B}$ to $\mathcal{B}'$ is the matrix whose columns are the $\mathcal{B}'$-coordinate vectors of the vectors in $\mathcal{B}$ and is denoted by ${}_{\mathcal{B}'}[I]_{\mathcal{B}}$. Such a matrix is also called a **transition matrix**.

Facts: The following facts can be found in [Lay03, Sects. 4.4 and 4.7] or [HJ85, Sect. 0.10]:

1. For any vector $\mathbf{x} \in F^n$ with the standard ordered basis $\mathcal{E}_n = (\mathbf{e}_1, \mathbf{e}_2, \ldots, \mathbf{e}_n)$, we have $\mathbf{x} = [\mathbf{x}]_{\mathcal{E}_n}$.
2. For any ordered basis $\mathcal{B} = (\mathbf{b}_1, \ldots, \mathbf{b}_n)$ of a vector space V, we have $[\mathbf{b}_i]_{\mathcal{B}} = \mathbf{e}_i$.
3. If $\dim(V) = n$, then the coordinate mapping is a one-to-one linear transformation from V onto F^n. (See Chapter 3 for the definition of linear transformation.)
4. If $\mathcal{B}$ is an ordered basis for a vector space V and $\mathbf{v}_1, \mathbf{v}_2 \in V$, then $\mathbf{v}_1 = \mathbf{v}_2$ if and only if $[\mathbf{v}_1]_{\mathcal{B}} = [\mathbf{v}_2]_{\mathcal{B}}$.
5. Let V be a vector space over a field F, and suppose $\mathcal{B}$ is an ordered basis for V. Then for any $\mathbf{x}, \mathbf{v}_1, \ldots, \mathbf{v}_k \in V$ and $c_1, \ldots, c_k \in F, \mathbf{x} = c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k$ if and only if $[\mathbf{x}]_{\mathcal{B}} = c_1[\mathbf{v}_1]_{\mathcal{B}} + \cdots + c_k[\mathbf{v}_k]_{\mathcal{B}}$. So, for any $\mathbf{x}, \mathbf{v}_1, \ldots, \mathbf{v}_k \in V$, $\mathbf{x} \in \text{Span}(\mathbf{v}_1, \ldots, \mathbf{v}_k)$ if and only if $[\mathbf{x}]_{\mathcal{B}} \in \text{Span}([\mathbf{v}_1]_{\mathcal{B}}, \ldots, [\mathbf{v}_k]_{\mathcal{B}})$.
6. Suppose $\mathcal{B}$ is an ordered basis for an n-dimensional vector space V over a field F and $\mathbf{v}_1, \ldots, \mathbf{v}_k \in V$. The set $S = \{\mathbf{v}_1, \ldots, \mathbf{v}_k\}$ is linearly independent in V if and only if the set $S' = \{[\mathbf{v}_1]_{\mathcal{B}}, \ldots, [\mathbf{v}_k]_{\mathcal{B}}\}$ is linearly independent in F^n.
7. Let V be a vector space over a field F with $\dim(V) = n$, and suppose $\mathcal{B}$ is an ordered basis for V. Then $\text{Span}(\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k) = V$ for some $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_k \in V$ if and only if $\text{Span}([\mathbf{v}_1]_{\mathcal{B}}, [\mathbf{v}_2]_{\mathcal{B}}, \ldots, [\mathbf{v}_k]_{\mathcal{B}}) = F^n$.
8. Suppose $\mathcal{B}$ is an ordered basis for a vector space V over a field F with $\dim(V) = n$, and let $S = \{\mathbf{v}_1, \ldots, \mathbf{v}_n\}$ be a subset of V. Then S is a basis for V if and only if $\{[\mathbf{v}_1]_{\mathcal{B}}, \ldots, [\mathbf{v}_n]_{\mathcal{B}}\}$ is a basis for F^n if and only if the matrix $[[\mathbf{v}_1]_{\mathcal{B}}, \ldots, [\mathbf{v}_n]_{\mathcal{B}}]$ is invertible.
9. If $\mathcal{B}$ and $\mathcal{B}'$ are ordered bases for a vector space V, then $[\mathbf{x}]_{\mathcal{B}'} = {}_{\mathcal{B}'}[I]_{\mathcal{B}}\ [\mathbf{x}]_{\mathcal{B}}$ for any $\mathbf{x} \in V$. Furthermore, ${}_{\mathcal{B}'}[I]_{\mathcal{B}}$ is the only matrix such that for any $\mathbf{x} \in V$, $[\mathbf{x}]_{\mathcal{B}'} = {}_{\mathcal{B}'}[I]_{\mathcal{B}}\ [\mathbf{x}]_{\mathcal{B}}$.
10. Any change-of-basis matrix is invertible.
11. If B is invertible, then B is a change-of-basis matrix. Specifically, if $B = [\mathbf{b}_1 \ \cdots \ \mathbf{b}_n] \in F^{n \times n}$, then $B = {}_{\mathcal{E}_n}[I]_{\mathcal{B}}$, where $\mathcal{B} = (\mathbf{b}_1, \ldots, \mathbf{b}_n)$ is an ordered basis for F^n.
12. If $\mathcal{B} = (\mathbf{b}_1, \ldots, \mathbf{b}_n)$ is an ordered basis for F^n, then ${}_{\mathcal{E}_n}[I]_{\mathcal{B}} = [\mathbf{b}_1 \ \cdots \ \mathbf{b}_n]$.

13. If $\mathcal{B}$ and $\mathcal{B}'$ are ordered bases for a vector space V, then ${}_{\mathcal{B}}[I]_{\mathcal{B}'} = ({}_{\mathcal{B}'}[I]_{\mathcal{B}})^{-1}$.
14. If $\mathcal{B}$ and $\mathcal{B}'$ are ordered bases for F^n, then ${}_{\mathcal{B}'}[I]_{\mathcal{B}} = ({}_{\mathcal{B}'}[I]_{\mathcal{E}_n})({}_{\mathcal{E}_n}[I]_{\mathcal{B}})$.

Examples:

1. If $p(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 \in F[x;n]$ with the standard ordered basis $\mathcal{B} = (1, x, x^2, \ldots, x^n)$, then $[p(x)]_{\mathcal{B}} = \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_n \end{bmatrix}$.
2. The set $\mathcal{B} = \left(\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix} \right)$ forms an ordered basis for $\mathbb{R}^2$. If $\mathcal{E}_2$ is the standard ordered basis for $\mathbb{R}^2$, then the change-of-basis matrix from $\mathcal{B}$ to $\mathcal{E}_2$ is ${}_{\mathcal{E}_2}[I]_{\mathcal{B}} = \begin{bmatrix} 1 & 0 \\ -1 & 3 \end{bmatrix}$, and $({}_{\mathcal{E}_2}[I]_{\mathcal{B}})^{-1} = \begin{bmatrix} 1 & 0 \\ \frac{1}{3} & \frac{1}{3} \end{bmatrix}$. So for $\mathbf{v} = \begin{bmatrix} 3 \\ 1 \end{bmatrix}$ in the standard ordered basis, we find that $[\mathbf{v}]_{\mathcal{B}} = ({}_{\mathcal{E}_2}[I]_{\mathcal{B}})^{-1}\mathbf{v} = \begin{bmatrix} 3 \\ \frac{4}{3} \end{bmatrix}$. To check this, we can easily see that $\mathbf{v} = \begin{bmatrix} 3 \\ 1 \end{bmatrix} = 3\begin{bmatrix} 1 \\ -1 \end{bmatrix} + \frac{4}{3}\begin{bmatrix} 0 \\ 3 \end{bmatrix}$.
3. The set $\mathcal{B}' = (1, 1+x, 1+x^2)$ is an ordered basis for $\mathbb{R}[x;2]$, and using the standard ordered basis $\mathcal{B} = (1, x, x^2)$ for $\mathbb{R}[x;2]$ we have ${}_{\mathcal{B}}[I]_{\mathcal{B}'} = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$. So, $({}_{\mathcal{B}}[I]_{\mathcal{B}'})^{-1} = \begin{bmatrix} 1 & -1 & -1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ and $[5 - 2x + 3x^2]_{\mathcal{B}'} = ({}_{\mathcal{B}}[I]_{\mathcal{B}'})^{-1} \begin{bmatrix} 5 \\ -2 \\ 3 \end{bmatrix} = \begin{bmatrix} 4 \\ -2 \\ 3 \end{bmatrix}$. Of course, we can see $5 - 2x + 3x^2 = 4(1) - 2(1+x) + 3(1+x^2)$.
4. If we want to change from the ordered basis $\mathcal{B}_1 = \left(\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix} \right)$ in $\mathbb{R}^2$ to the ordered basis $\mathcal{B}_2 = \left(\begin{bmatrix} 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 5 \\ 0 \end{bmatrix} \right)$, then the resulting change-of-basis matrix is ${}_{\mathcal{B}_2}[I]_{\mathcal{B}_1} = ({}_{\mathcal{E}_2}[I]_{\mathcal{B}_2})^{-1}({}_{\mathcal{E}_2}[I]_{\mathcal{B}_1}) = \begin{bmatrix} 2 & 5 \\ 1 & 0 \end{bmatrix}^{-1} \begin{bmatrix} 1 & 0 \\ -1 & 3 \end{bmatrix} = \begin{bmatrix} -1 & 3 \\ \frac{3}{5} & -\frac{6}{5} \end{bmatrix}$.
5. Let $S = \{5 - 2x + 3x^2, 3 - x + 2x^2, 8 + 3x\}$ in $\mathbb{R}[x;2]$ with the standard ordered basis $\mathcal{B} = (1, x, x^2)$. The matrix $A = \begin{bmatrix} 5 & 3 & 8 \\ -2 & -1 & 3 \\ 3 & 2 & 0 \end{bmatrix}$ contains the $\mathcal{B}$-coordinate vectors for the polynomials in S and it has row echelon form $\begin{bmatrix} 5 & 3 & 8 \\ 0 & 1 & 31 \\ 0 & 0 & 1 \end{bmatrix}$. Since this row echelon form shows that A is nonsingular, we know by Fact 8 that S is a basis for $\mathbb{R}[x;2]$.

2.7 Idempotence and Nilpotence

Definitions:

A is an **idempotent** if $A^2 = A$.

A is **nilpotent** if, for some $k \geq 0$, $A^k = 0$.

Facts: All of the following facts except those with a specific reference are immediate from the definitions.

1. Every idempotent except the identity matrix is singular.
2. Let $A \in F^{n\times n}$. The following statements are equivalent.
   (a) A is an idempotent.
   (b) $I - A$ is an idempotent.
   (c) If $\mathbf{v} \in \text{range}(A)$, then $A\mathbf{v} = \mathbf{v}$.
   (d) $F^n = \ker A \oplus \text{range} A$.
   (e) [HJ85, p. 37 and p. 148] A is similar to $\begin{bmatrix} I_k & 0 \\ 0 & 0 \end{bmatrix}$, for some $k \leq n$.
3. If A_1 and A_2 are idempotents of the same size and commute, then A_1A_2 is an idempotent.
4. If A_1 and A_2 are idempotents of the same size and $A_1A_2 = A_2A_1 = 0$, then $A_1 + A_2$ is an idempotent.
5. If $A \in F^{n\times n}$ is nilpotent, then $A^n = 0$.
6. If A is nilpotent and B is of the same size and commutes with A, then AB is nilpotent.
7. If A_1 and A_2 are nilpotent matrices of the same size and $A_1A_2 = A_2A_1 = 0$, then $A_1 + A_2$ is nilpotent.

Examples:

1. $\begin{bmatrix} -8 & 12 \\ -6 & 9 \end{bmatrix}$ is an idempotent. $\begin{bmatrix} 1 & -1 \\ 1 & -1 \end{bmatrix}$ is nilpotent.

3.1 Basic Concepts

Let V, W be vector spaces over a field F.

Definitions:

A **linear transformation** (or **linear mapping**) is a mapping $T\colon V \to W$ such that, for each $\mathbf{u}, \mathbf{v} \in V$, and for each $c \in F$, $T(\mathbf{u}+\mathbf{v}) = T(\mathbf{u}) + T(\mathbf{v})$, and $T(c\mathbf{u}) = cT(\mathbf{u})$.

V is called the **domain** of the linear transformation $T : V \to W$.

W is called the **codomain** of the linear transformation $T : V \to W$.

The **identity** transformation $I_V\colon V \to V$ is defined by $I_V(\mathbf{v}) = \mathbf{v}$ for each $\mathbf{v} \in V$. I_V is also denoted by I.

The **zero** transformation $0\colon V \to W$ is defined by $0(\mathbf{v}) = \mathbf{0}_W$ for each $\mathbf{v} \in V$.

A **linear operator** is a linear transformation $T\colon V \to V$.

Facts:

Let $T\colon V \to W$ be a linear transformation. The following facts can be found in almost any elementary linear algebra text, including [Lan70, IV§1], [Sta69, §3.1], [Goo03, Chap. 4], and [Lay03, §1.8].

1. $T(\sum_1^n a_i\mathbf{v}_i) = \sum_1^n a_i T(\mathbf{v}_i)$, for any $a_i \in F$, $\mathbf{v}_i \in V$, $i = 1, \ldots, n$.
2. $T(\mathbf{0}_V) = \mathbf{0}_W$.
3. $T(-\mathbf{v}) = -T(\mathbf{v})$, for each $\mathbf{v} \in V$.
4. The identity transformation is a linear transformation.
5. The zero transformation is a linear transformation.
6. If $\mathcal{B} = \{\mathbf{v}_1, \ldots, \mathbf{v}_n\}$ is a basis for V, and $\mathbf{w}_1, \ldots, \mathbf{w}_n \in W$, then there exists a unique $T\colon V \to W$ such that $T(\mathbf{v}_i) = \mathbf{w}_i$ for each i.

Examples:

Examples 1 to 9 are linear transformations.

1. $T:\mathbb{R}^3 \to \mathbb{R}^2$ where $T\left(\begin{bmatrix} x \\ y \\ z \end{bmatrix}\right) = \begin{bmatrix} x+y \\ 2x-z \end{bmatrix}$.
2. $T:V \to V$, defined by $T(\mathbf{v}) = -\mathbf{v}$ for each $\mathbf{v} \in V$.
3. If $A \in F^{m\times n}$, $T:F^n \to F^m$, where $T(\mathbf{v}) = A\mathbf{v}$.
4. $T:F^{m\times n} \to F$, where $T(A) = \operatorname{tr} A$.
5. Let $\mathcal{C}([0,1])$ be the vector space of all continuous functions on $[0,1]$ into $\mathbb{R}$, and let $T:\mathcal{C}([0,1]) \to \mathbb{R}$ be defined by $T(f) = \int_0^1 f(t)dt$.
6. Let V be the vector space of all functions $f:\mathbb{R} \to \mathbb{R}$ that have derivatives of all orders, and $D: V \to V$ be defined by $D(f) = f'$.
7. The transformation, which rotates every vector in the plane $\mathbb{R}^2$ through an angle θ.
8. The projection T onto the xy-plane of $\mathbb{R}^3$, i.e., $T\left(\begin{bmatrix} x \\ y \\ z \end{bmatrix}\right) = \begin{bmatrix} x \\ y \\ 0 \end{bmatrix}$.
9. $T: \mathbb{R}^3 \to \mathbb{R}^3$, where $T(\mathbf{v}) = \mathbf{b} \times \mathbf{v}$, for some $\mathbf{b} \in \mathbb{R}^3$.

Examples 10 and 11 are not linear transformations.

10. $f: \mathbb{R}^2 \to \mathbb{R}^2$, where $f\left(\begin{bmatrix} x \\ y \end{bmatrix}\right) = \begin{bmatrix} y+1 \\ x-y-2 \end{bmatrix}$ is not a linear transformation because $f(\mathbf{0}) \neq \mathbf{0}$.
11. $f: \mathbb{R}^2 \to \mathbb{R}$, where $f\left(\begin{bmatrix} x \\ y \end{bmatrix}\right) = x^2$ is not a linear transformation because $f\left(2\begin{bmatrix} 1 \\ 0 \end{bmatrix}\right) = 4 \neq 2 = 2f\left(\begin{bmatrix} 1 \\ 0 \end{bmatrix}\right)$.

3.2 The Spaces $L(V, W)$ and $L(V, V)$

Let V, W be vector spaces over F.

Definitions:

$L(V, W)$ denotes the set of all linear transformations of V into W.

For each $T_1, T_2 \in L(V, W)$ the **sum** $T_1 + T_2$ is defined by $(T_1 + T_2)(\mathbf{v}) = T_1(\mathbf{v}) + T_2(\mathbf{v})$.

For each $c \in F$, $T \in L(V, W)$ the **scalar multiple** cT is defined by $(cT)(\mathbf{v}) = cT(\mathbf{v})$.

For each $T_1, T_2 \in L(V, V)$ the **product** T_1T_2 is the composite mapping defined by $(T_1T_2)(\mathbf{v}) = T_1(T_2(\mathbf{v}))$.

$T_1, T_2 \in L(V, V)$ **commute** if $T_1T_2 = T_2T_1$.

$T \in L(V, V)$ is a **scalar transformation** if, for some $c \in F$, $T(\mathbf{v}) = c\mathbf{v}$ for each $\mathbf{v} \in V$.

Facts:

Let $T, T_1, T_2 \in L(V, W)$. The following facts can be found in almost any elementary linear algebra text, including [Fin60, §3.2], [Lan70, IV §4], [Sta69, §3.6], [SW68, §4.3], and [Goo03, Chap. 4].

1. $T_1 + T_2 \in L(V, W)$.
2. $cT \in L(V, W)$.
3. If $T_1, T_2 \in L(V, V)$, then $T_1T_2 \in L(V, V)$.
4. $L(V, W)$, with sum and scalar multiplication, is a vector space over F.
5. $L(V, V)$, with sum, scalar multiplication, and composition, is a linear algebra over F.
6. Let $\dim V = n$ and $\dim W = m$. Then $\dim L(V, W) = mn$.

7. If $\dim V > 1$, then there exist $T_1, T_2 \in L(V, V)$, which do not commute.
8. $T_0 \in L(V, V)$ commutes with all $T \in L(V, V)$ if and only if T_0 is a scalar transformation.

Examples:

1. For each $j = 1, \ldots, n$ let $T_j \in L(F^n, F^n)$ be defined by $T_j(\mathbf{x}) = x_j \mathbf{e}_j$. Then $\sum_{i=1}^n T_j$ is the identity transformation in V.
2. Let T_1 and T_2 be the transformations that rotates every vector in $\mathbb{R}^2$ through an angle θ_1 and θ_2 respectively. Then $T_1 T_2$ is the rotation through the angle $\theta_1 + \theta_2$.
3. Let T_1 be the rotation through an angle θ in $\mathbb{R}^2$ and let T_2 be the reflection on the horizontal axis, that is, $T_2(x, y) = (x, -y)$. Then T_1 and T_2 do not commute.

3.3 Matrix of a Linear Transformation

Let V, W be nonzero finite dimensional vector spaces over F.

Definitions:

The **linear transformation associated to a matrix** $A \in F^{m \times n}$ is $T_A \colon F^n \to F^m$ defined by $T_A(\mathbf{v}) = A\mathbf{v}$.

The **matrix associated to a linear transformation** $T \in L(V, W)$ and relative to the ordered bases $\mathcal{B} = (\mathbf{b}_1, \ldots, \mathbf{b}_n)$ of V, and $\mathcal{C}$ of W, is the matrix ${}_{\mathcal{C}}[T]_{\mathcal{B}} = [[T(\mathbf{b}_1)]_{\mathcal{C}} \ \cdots \ [T(\mathbf{b}_n)]_{\mathcal{C}}]$.

If $T \in L(F^n, F^m)$, then the **standard matrix** of T is $[T] = {}_{\mathcal{E}_m}[T]_{\mathcal{E}_n}$, where $\mathcal{E}_n$ is the standard basis for F^n.

Note: If $V = W$ and $\mathcal{B} = \mathcal{C}$, the matrix ${}_{\mathcal{B}}[T]_{\mathcal{B}}$ will be denoted by $[T]_{\mathcal{B}}$.

If $T \in L(V, V)$ and $\mathcal{B}$ is an ordered basis for V, then the **trace** of T is $\operatorname{tr} T = \operatorname{tr} [T]_{\mathcal{B}}$.

Facts:

Let $\mathcal{B}$ and $\mathcal{C}$ be ordered bases V and W, respectively. The following facts can be found in almost any elementary linear algebra text, including [Lan70, V §2], [Sta69, §3.4–3.6], [SW68, §4.3], and [Goo03, Chap. 4].

1. The trace of $T \in L(V, V)$ is independent of the ordered basis of V used to define it.
2. For $A, B \in F^{m \times n}$, $T_A = T_B$ if and only if $A = B$.
3. For any $T_1, T_2 \in L(V, W)$, ${}_{\mathcal{C}}[T_1]_{\mathcal{B}} = {}_{\mathcal{C}}[T_2]_{\mathcal{B}}$ if and only if $T_1 = T_2$.
4. If $T \in L(F^n, F^m)$, then $[T] = [T(\mathbf{e}_1) \cdots T(\mathbf{e}_n)]$.
5. The change-of-basis matrix from basis $\mathcal{B}$ to $\mathcal{C}$, ${}_{\mathcal{C}}[I]_{\mathcal{B}}$, as defined in Section 2.6, is the same matrix as the matrix of the identity transformation with respect to $\mathcal{B}$ and $\mathcal{C}$.
6. Let $A \in F^{m \times n}$ and let T_A be the linear transformation associated to A. Then $[T_A] = A$.
7. If $T \in L(F^n, F^m)$, then $T_{[T]} = T$.
8. For any $T_1, T_2 \in L(V, W)$, ${}_{\mathcal{C}}[T_1 + T_2]_{\mathcal{B}} = {}_{\mathcal{C}}[T_1]_{\mathcal{B}} + {}_{\mathcal{C}}[T_2]_{\mathcal{B}}$.
9. For any $T \in L(V, W)$, and $c \in F$, ${}_{\mathcal{C}}[cT]_{\mathcal{B}} = c\,{}_{\mathcal{C}}[T]_{\mathcal{B}}$.
10. For any $T_1, T_2 \in L(V, V)$, $[T_1 T_2]_{\mathcal{B}} = [T_1]_{\mathcal{B}}\,[T_2]_{\mathcal{B}}$.
11. If $T \in L(V, W)$, then, for each $\mathbf{v} \in V$, $[T(\mathbf{v})]_{\mathcal{C}} = {}_{\mathcal{C}}[T]_{\mathcal{B}}\,[\mathbf{v}]_{\mathcal{B}}$. Furthermore, ${}_{\mathcal{C}}[T]_{\mathcal{B}}$ is the only matrix A such that, for each $\mathbf{v} \in V$, $[T(\mathbf{v})]_{\mathcal{C}} = A[\mathbf{v}]_{\mathcal{B}}$.

Examples:

1. Let T be the projection of $\mathbb{R}^3$ onto the xy-plane of $\mathbb{R}^3$. Then

$$[T] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

2. Let T be the identity in F^n. Then $[T]_{\mathcal{B}} = I_n$.
3. Let T be the rotation by θ in $\mathbb{R}^2$. Then

$$[T] = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}.$$

4. Let $D\colon \mathbb{R}[x;n] \to \mathbb{R}[x;n-1]$ be the derivative transformation, and let $\mathcal{B} = \{1, x, \ldots, x^n\}$, $\mathcal{C} = \{1, x, \ldots, x^{n-1}\}$. Then

$${}_{\mathcal{C}}[T]_{\mathcal{B}} = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & n-1 \end{bmatrix}.$$

3.4 Change of Basis and Similarity

Let V, W be nonzero finite dimensional vector spaces over F.

Facts:

The following facts can be found in [Gan60, III §5–6] and [Goo03, Chap. 4].

1. Let $T \in L(V,W)$ and let $\mathcal{B}, \mathcal{B}'$ be bases of V, $\mathcal{C}, \mathcal{C}'$ be bases of W. Then

$${}_{\mathcal{C}'}[T]_{\mathcal{B}'} = {}_{\mathcal{C}'}[I]_{\mathcal{C}}\,{}_{\mathcal{C}}[T]_{\mathcal{B}}\,{}_{\mathcal{B}}[I]_{\mathcal{B}'}.$$

2. Two $m \times n$ matrices are equivalent if and only if they represent the same linear transformation $T \in L(V,W)$, but possibly in different bases, as in Fact 1.
3. Any $m \times n$ matrix A of rank r is equivalent to the $m \times n$ matrix

$$\tilde{I}_r = \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix}.$$

4. Two $m \times n$ matrices are equivalent if and only if they have the same rank.
5. Two $n \times n$ matrices are similar if and only if they represent the same linear transformation $T \in L(V,V)$, but possibly in different bases, i.e., if A_1 is similar to A_2, then there is $T \in L(V,V)$ and ordered bases $\mathcal{B}_1, \mathcal{B}_2$ of V such that $A_i = [T]_{\mathcal{B}_i}$ and conversely.

Examples:

1. Let T be the projection on the x-axis of $\mathbb{R}^2$, i.e., $T(x,y) = (x,0)$. If $\mathcal{B} = \{\mathbf{e}_1, \mathbf{e}_2\}$ and $\mathcal{C} = \{\mathbf{e}_1 + \mathbf{e}_2, \mathbf{e}_1 - \mathbf{e}_2\}$, then $[T]_{\mathcal{B}} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$, $[T]_{\mathcal{C}} = \begin{bmatrix} 1/2 & 1/2 \\ 1/2 & 1/2 \end{bmatrix}$, and $[T]_{\mathcal{C}} = Q^{-1}[T]_{\mathcal{B}}Q$ with $Q = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$.

3.5 Kernel and Range

Let V, W be vector spaces over F and let $T \in L(V, W)$.

Definitions:

T is **one-to-one** (or **injective**) if $\mathbf{v}_1 \neq \mathbf{v}_2$ implies $T(\mathbf{v}_1) \neq T(\mathbf{v}_2)$.

The **kernel** (or **null space**) of T is the set $\ker T = \{\mathbf{v} \in V \mid T(\mathbf{v}) = \mathbf{0}\}$.

The **nullity** of T, denoted by $\operatorname{null} T$, is the dimension of $\ker T$.

T is **onto** (or **surjective**) if, for each $\mathbf{w} \in W$, there exists $\mathbf{v} \in V$ such that $T(\mathbf{v}) = \mathbf{w}$.

The **range** (or **image**) of T is the set $\operatorname{range} T = \{\mathbf{w} \in W \mid \exists \mathbf{v}, \mathbf{w} = T(\mathbf{v})\}$.

The **rank** of T, denoted by $\operatorname{rank} T$, is the dimension of $\operatorname{range} T$.

Facts:

The following facts can be found in [Fin60, §3.3], [Lan70, IV §3], [Sta69, §3.1–3.2], and [Goo03, Chap. 4].

1. $\ker T$ is a subspace of V.
2. The following statements are equivalent.
   (a) T is one-to-one.
   (b) $\ker T = \{\mathbf{0}\}$.
   (c) Each linearly independent set is mapped to a linearly independent set.
   (d) Each basis is mapped to a linearly independent set.
   (e) Some basis is mapped to a linearly independent set.
3. $\operatorname{range} T$ is a subspace of W.
4. $\operatorname{rank} T = \operatorname{rank}{}_{\mathcal{C}}[T]_{\mathcal{B}}$ for any finite nonempty ordered bases $\mathcal{B}, \mathcal{C}$.
5. For $A \in F^{m\times n}$, $\ker T_A = \ker A$ and $\operatorname{range} T_A = \operatorname{range} A$.
6. (Dimension Theorem) Let $T \in L(V, W)$ where V has finite dimension. Then $\operatorname{null} T + \operatorname{rank} T = \dim V$.
7. Let $T \in L(V, V)$, where V has finite dimension, then T is one-to-one if and only if T is onto.
8. Let $T(\mathbf{v}) = \mathbf{w}$. Then $\{\mathbf{u} \in V \mid T(\mathbf{u}) = \mathbf{w}\} = \mathbf{v} + \ker T$.
9. Let $V = \operatorname{Span}\{\mathbf{v}_1, \dots, \mathbf{v}_n\}$. Then $\operatorname{range} T = \operatorname{Span}\{T(\mathbf{v}_1), \dots, T(\mathbf{v}_n)\}$.
10. Let $T_1, T_2 \in L(V, V)$. Then $\ker T_1T_2 \supseteq \ker T_2$ and $\operatorname{range} T_1T_2 \subseteq \operatorname{range} T_1$.
11. Let $T \in L(V, V)$. Then

$$\{\mathbf{0}\} \subseteq \ker T \subseteq \ker T^2 \subseteq \cdots \subseteq \ker T^k \subseteq \cdots$$
$$V \supseteq \operatorname{range} T \supseteq \operatorname{range} T^2 \supseteq \cdots \supseteq \operatorname{range} T^k \supseteq \cdots.$$

   Furthermore, if, for some k, $\operatorname{range} T^{k+1} = \operatorname{range} T^k$, then, for each $i \geqslant 1$, $\operatorname{range} T^{k+i} = \operatorname{range} T^k$. If, for some k, $\ker T^{k+1} = \ker T^k$, then, for each $i \geqslant 1$, $\ker T^{k+i} = \ker T^k$.

Examples:

1. Let T be the projection of $\mathbb{R}^3$ onto the xy-plane of $\mathbb{R}^3$. Then $\ker T = \{(0, 0, z) \colon z \in \mathbb{R}\}$; $\operatorname{range} T = \{(x, y, 0) \colon x, y \in \mathbb{R}\}$; $\operatorname{null} T = 1$; and $\operatorname{rank} T = 2$.
2. Let T be the linear transformation in Example 3.1.1. Then $\ker T = \operatorname{Span}\{[1 \ -1 \ 2]^T\}$, while $\operatorname{range} T = \mathbb{R}^2$.
3. Let $D \in L(\mathbb{R}[x], \mathbb{R}[x])$ be the derivative transformation, then $\ker D$ consists of all constant polynomials, while $\operatorname{range} D = \mathbb{R}[x]$. In particular, D is onto but is not one-to-one. Note that $\mathbb{R}[x]$ is not finite dimensional.

4. Let $T_1, T_2 \in L(F^{n\times n}, F^{n\times n})$ where $T_1(A) = \frac{1}{2}(A - A^T)$, $T_2(A) = \frac{1}{2}(A + A^T)$, then

$$\begin{aligned} \ker T_1 &= \operatorname{range} T_2 = \{n \times n \text{ symmetric matrices}\}; \\ \ker T_2 &= \operatorname{range} T_1 = \{n \times n \text{ skew-symmetric matrices}\}; \\ \operatorname{null} T_1 &= \operatorname{rank} T_2 = \frac{n(n+1)}{2}; \qquad \operatorname{null} T_2 = \operatorname{rank} T_1 = \frac{n(n-1)}{2}. \end{aligned}$$

5. Let $T(\mathbf{v}) = \mathbf{b} \times \mathbf{v}$ as in Example 3.1.9. Then $\ker T = \operatorname{Span}\{\mathbf{b}\}$.

3.6 Invariant Subspaces and Projections

Let V be a vector space over F, and let $V = V_1 \oplus V_2$ for some V_1, V_2 subspaces of V. For each $\mathbf{v} \in V$, let $\mathbf{v}_i \in V_i$ denote the (unique) vector such that $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2$ (see Section 2.3). Finally, let $T \in L(V, V)$.

Definitions:

For $i, j \in \{1, 2\}$, $i \neq j$, the **projection** onto V_i along V_j is the operator $\operatorname{proj}_{V_i,V_j} : V \to V$ defined by $\operatorname{proj}_{V_i,V_j}(\mathbf{v}) = \mathbf{v}_i$ for each $\mathbf{v} \in V$ (see also Chapter 5).

The **complementary projection** of the projection $\operatorname{proj}_{V_i,V_j}$ is the projection $\operatorname{proj}_{V_j,V_i}$.

T is an **idempotent** if $T^2 = T$.

A subspace V_0 of V is **invariant** under T or **T-invariant** if $T(V_0) \subseteq V_0$.

The **fixed space** of T is $\operatorname{fix} T = \{\mathbf{v} \in V \mid T(\mathbf{v}) = \mathbf{v}\}$.

T is **nilpotent** if, for some $k \geqslant 0$, $T^k = 0$.

Facts:

The following facts can be found in [Mal63, §43–44].

1. $\operatorname{proj}_{V_i,V_j} \in L(V, V)$.
2. $\operatorname{proj}_{V_1,V_2} + \operatorname{proj}_{V_2,V_1} = I$, the identity linear operator in V.
3. $\operatorname{range}(\operatorname{proj}_{V_i,V_j}) = \ker(\operatorname{proj}_{V_j,V_i}) = V_i$.
4. Sum and intersection of invariant subspaces are invariant subspaces.
5. If V has a nonzero subspace different from V that is invariant under T, then there exists a suitable ordered basis $\mathcal{B}$ of V such that $[T]_{\mathcal{B}} = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix}$. Conversely, if $[T]_{\mathcal{B}} = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix}$, where A_{11} is an $m \times m$ block, then the subspace spanned by the first m vectors in $\mathcal{B}$ is a T-invariant subspace.
6. Let T have two nonzero finite dimensional invariant subspaces V_1 and V_2, with ordered bases $\mathcal{B}_1$ and $\mathcal{B}_2$, respectively, such that $V_1 \oplus V_2 = V$. Let $T_1 \in L(V_1, V_1)$, $T_2 \in L(V_2, V_2)$ be the restrictions of T on V_1 and V_2, respectively, and let $\mathcal{B} = \mathcal{B}_1 \cup \mathcal{B}_2$. Then $[T]_{\mathcal{B}} = [T_1]_{\mathcal{B}_1} \oplus [T_2]_{\mathcal{B}_2}$.

The following facts can be found in [Hoh64, §6.15; §6.20].

7. Every idempotent except the identity is singular.
8. The statements 8(a) through 8(e) are equivalent. If V is finite dimensional, statement 8(f) is also equivalent to these statements.
   (a) T is an idempotent.
   (b) $I - T$ is an idempotent.

   (c) $\operatorname{fix} T = \operatorname{range} T$.
   (d) $V = \ker T \oplus \operatorname{fix} T$.
   (e) T is the projection onto V_1 along V_2 for some V_1, V_2, with $V = V_1 \oplus V_2$.
   (f) There exists a basis $\mathcal{B}$ of V such that $[T]_{\mathcal{B}} = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}$.

9. If T_1 and T_2 are idempotents on V and commute, then T_1T_2 is an idempotent.
10. If T_1 and T_2 are idempotents on V and $T_1T_2 = T_2T_1 = 0$, then $T_1 + T_2$ is an idempotent.
11. If $\dim V = n$ and $T \in L(V, V)$ is nilpotent, then $T^n = 0$.

Examples:

1. Example 3.1.8, $T\colon \mathbb{R}^3 \to \mathbb{R}^3$, where $T\left(\begin{bmatrix} x \\ y \\ z \end{bmatrix}\right) = \begin{bmatrix} x \\ y \\ 0 \end{bmatrix}$ is the projection onto $\operatorname{Span}\{\mathbf{e}_1, \mathbf{e}_2\}$ along $\operatorname{Span}\{\mathbf{e}_3\}$.
2. The zero subspace is T-invariant for any T.
3. T_1 and T_2, defined in Example 3.5.4, are the projection of $F^{n\times n}$ onto the subspace of $n \times n$ symmetric matrices along the subspace of $n\times n$ skew-symmetric matrices, and the projection of $F^{n\times n}$ onto the skew-symmetric matrices along the symmetric matrices, respectively.
4. Let T be a nilpotent linear transformation on V. Let $T^p = 0$ and $T^{p-1}(\mathbf{v}) \neq 0$. Then $S = \operatorname{Span}\{\mathbf{v}, T(\mathbf{v}), T^2(\mathbf{v}), \dots, T^{p-1}(\mathbf{v})\}$ is a T-invariant subspace.

3.7 Isomorphism and Nonsingularity Characterization

Let U, V, W be vector spaces over F and let $T \in L(V, W)$.

Definitions:

T is **invertible** (or an **isomorphism**) if there exists a function $S\colon W \to V$ such that $ST = I_V$ and $TS = I_W$. S is called the **inverse** of T and is denoted by T^{-1}.
V and W are **isomorphic** if there exists an isomorphism of V onto W.
T is **nonsingular** if $\ker T = \{\mathbf{0}\}$; otherwise T is **singular**.

Facts:

The following facts can be found in [Fin60, §3.4], [Hoh64, §6.11], and [Lan70, IV §4]:

1. The inverse is unique.
2. T^{-1} is a linear transformation, invertible, and $(T^{-1})^{-1} = T$.
3. If $T_1 \in L(V, W)$ and $T_2 \in L(U, V)$, then T_1T_2 is invertible if and only if T_1 and T_2 are invertible.
4. If $T_1 \in L(V, W)$ and $T_2 \in L(U, V)$, then $(T_1T_2)^{-1} = T_2^{-1}T_1^{-1}$.
5. Let $T \in L(V, W)$, and let $\dim V = \dim W = n$. The following statements are equivalent:
   (a) T is invertible.
   (b) T is nonsingular.
   (c) T is one-to-one.
   (d) $\ker T = \{\mathbf{0}\}$.
   (e) $\operatorname{null} T = 0$.

   (f) T is onto.
   (g) $\operatorname{range} T = W$.
   (h) $\operatorname{rank} T = n$.
   (i) T maps some bases of V to bases of W.
6. If V and W are isomorphic, then $\dim V = \dim W$.
7. If $\dim V = n > 0$, then V is isomorphic to F^n through φ defined by $\varphi(\mathbf{v}) = [\mathbf{v}]_{\mathcal{B}}$ for any ordered basis $\mathcal{B}$ of V.
8. Let $\dim V = n > 0$, $\dim W = m > 0$, and let $\mathcal{B}$ and $\mathcal{C}$ be ordered bases of V and W, respectively. Then $L(V, W)$ and $F^{m\times n}$ are isomorphic through φ defined by $\varphi(T) = {}_{\mathcal{C}}[T]_{\mathcal{B}}$.

Examples:

1. $V = F[x; n]$ and $W = F^{n+1}$ are isomorphic through $T \in L(V, W)$ defined by $T(\sum_0^n a_i x^i) = [a_0 \dots a_n]^T$.
2. If V is an infinite dimensional vector space, a nonsingular linear operator $T \in L(V, V)$ need not be invertible. For example, let $T \in L(\mathbb{R}[x], \mathbb{R}[x])$ be defined by $T(p(x)) = xp(x)$. Then T is nonsingular but not invertible since T is not onto. For matrices, nonsingular and invertible are equivalent, since an $n \times n$ matrix over F is an operator on the finite dimensional vector F^n.

3.8 Linear Functionals and Annihilator

Let V, W be vector spaces over F.

Definitions:

A **linear functional** (or **linear form**) on V is a linear transformation from V to F.

The **dual space** of V is the vector space $V^* = L(V, F)$ of all linear functionals on V.

If V is nonzero and finite dimensional, the **dual basis** of a basis $\mathcal{B} = \{\mathbf{v}_1, \dots, \mathbf{v}_n\}$ of V is the set $\mathcal{B}^* = \{f_1, \dots, f_n\} \subseteq V^*$, such that $f_i(\mathbf{v}_j) = \delta_{ij}$ for each i, j.

The **bidual space** is the vector space $V^{**} = (V^*)^* = L(V^*, F)$.

The **annihilator** of a set $S \subseteq V$ is $S^a = \{f \in V^* \mid f(\mathbf{v}) = 0, \forall \mathbf{v} \in S\}$.

The **transpose** of $T \in L(V, W)$ is the mapping $T^T \in L(W^*, V^*)$ defined by setting, for each $g \in W^*$,

$$\begin{aligned} T^T(g): V &\to F \\ \mathbf{v} &\mapsto g(T(\mathbf{v})). \end{aligned}$$

Facts:

The following facts can be found in [Hoh64, §6.19] and [SW68, §4.4].

1. For each $\mathbf{v} \in V$, $\mathbf{v} \neq 0$, there exists $f \in V^*$ such that $f(\mathbf{v}) \neq 0$.
2. For each $\mathbf{v} \in V$ define $h_{\mathbf{v}} \in L(V^*, F)$ by setting $h_{\mathbf{v}}(f) = f(\mathbf{v})$. Then the mapping

$$\begin{aligned} \varphi: V &\to V^{**} \\ \mathbf{v} &\mapsto h_{\mathbf{v}} \end{aligned}$$

   is a one-to-one linear transformation. If V is finite dimensional, φ is an isomorphism of V onto V^{**}.
3. S^a is a subspace of V^*.
4. $\{0\}^a = V^*$; $V^a = \{0\}$.

5. $S^a = (\text{Span}\{S\})^a$.

The following facts hold for finite dimensional vector spaces.

6. If V is nonzero, for each basis $\mathcal{B}$ of V, the dual basis exists, is uniquely determined, and is a basis for V^*.
7. $\dim V = \dim V^*$.
8. If V is nonzero, each basis of V^* is the dual basis of some basis of V.
9. Let $\mathcal{B}$ be a basis for the nonzero vector space V. For each $\mathbf{v} \in V$, $f \in V^*$, $f(\mathbf{v}) = [f]_{\mathcal{B}^*}^T[\mathbf{v}]_{\mathcal{B}}$.
10. If S is a subspace of V, then $\dim S + \dim S^a = \dim V$.
11. If S is a subspace of V, then, by identifying V and V^{**}, $S = (S^a)^a$.
12. Let S_1, S_2 be subspaces of V such that $S_1^a = S_2^a$. Then $S_1 = S_2$.
13. Any subspace of V^* is the annihilator of some subspace S of V.
14. Let S_1, S_2 be subspaces of V. Then $(S_1 \cap S_2)^a = S_1^a + S_2^a$ and $(S_1 + S_2)^a = S_1^a \cap S_2^a$.
15. $\ker T^T = (\text{range}\, T)^a$.
16. $\text{rank}\, T = \text{rank}\, T^T$.
17. If $\mathcal{B}$ and $\mathcal{C}$ are nonempty bases of V and W, respectively, then ${}_{\mathcal{B}^*}[T^T]_{\mathcal{C}^*} = \left({}_{\mathcal{C}}[T]_{\mathcal{B}}\right)^T$.

Examples:

1. Let $V = \mathcal{C}[a,b]$ be the vector space of continuous functions $\varphi\colon [a,b] \to \mathbb{R}$, and let $c \in [a,b]$. Then $f(\varphi) = \varphi(c)$ is a linear functional on V.
2. Let $V = \mathcal{C}[a,b]$, $\psi \in V$, and $f(\varphi) = \int_a^b \varphi(t)\psi(t)dt$. Then f is a linear functional.
3. The trace is a linear functional on $F^{n\times n}$.
4. let $V = F^{m\times n}$. $\mathcal{B} = \{E_{ij}\colon 1 \leqslant i \leqslant m, 1 \leqslant j \leqslant n\}$ is a basis for V. The dual basis $\mathcal{B}^*$ consists of the linear functionals f_{ij}, $1 \leqslant i \leqslant m, 1 \leqslant j \leqslant n$, defined by $f_{ij}(A) = a_{ij}$.

Throughout this chapter, F denotes an arbitrary field. All matrices are assumed to be in $F^{n\times n}$, unless otherwise stated. A vector space V is assumed to be a vector space over a field F.

4.1 Determinants

Definitions:

The **determinant**, $\det A$, of a matrix $A = [a_{ij}]$ is an element in F defined inductively:

- $\det [a] = a$.
- For $i, j \in \{1, 2, \ldots, n\}$, the ij**th minor** of A corresponding to a_{ij} is defined by $m_{ij} = \det A(\{i\}, \{j\})$, where $A(\{i\}, \{j\})$ denotes the submatrix of A obtained by deleting the ith row and the jth column.
- The ij**th cofactor** of a_{ij} is $c_{ij} = (-1)^{i+j} m_{ij}$.
- $\det A = \sum_{j=1}^{n} (-1)^{1+j} a_{1j} m_{1j} = \sum_{j=1}^{n} a_{1j} c_{1j}$.

This method of computing the determinant of a matrix is called **Laplace expansion of the determinant by signed minors along the first row** or **Laplace expansion of the determinant by cofactors along the first row**.

A $k \times k$ **minor** is $\det A[\alpha, \beta]$, where α is a set of k row indices and β is a set of k column indices ($k \geq 1$).

The **determinant of a linear operator** $T : V \to V$ on a finite dimensional vector space, V, over a field F is defined as $\det(T) = \det([T]_{\mathcal{B}})$, where $\mathcal{B}$ is a basis for V (see Section 3.3 for information about $[T]_{\mathcal{B}}$).

For a historical development of determinants see [Mui69].

Facts:

All the following facts except those with a specific reference can be found in [Hog87, pp. 94–156], [Lay12, pp. 163–187], [Gol07, pp. 199–228] or [Mey00, pp. 459–488].

1. $\det \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = a_{11}a_{22} - a_{12}a_{21}$.
2. $\det A = \det \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} = a_{11}a_{22}a_{33} + a_{21}a_{13}a_{32} + a_{31}a_{12}a_{23} - a_{31}a_{13}a_{22} - a_{21}a_{12}a_{33} - a_{11}a_{32}a_{23}$.

3. (The determinant is independent of the row i used to evaluate it) Let $i \in \{1, 2, \dots, n\}$. Then $\det A = \sum_{j=1}^{n} (-1)^{i+j} a_{ij} m_{ij} = \sum_{j=1}^{n} a_{ij} c_{ij}$.
4. (Expansion of the determinant by minors along the jth column) Let $j \in \{1, 2, \dots, n\}$. Then $\det A = \sum_{i=1}^{n} (-1)^{i+j} a_{ij} m_{ij} = \sum_{i=1}^{n} a_{ij} c_{ij}$.
5. $\det I_n = 1$.
6. If A is a triangular matrix, then $\det A = a_{11} a_{22} \cdots a_{nn}$.
7. If B is a matrix obtained from A by interchanging two rows (or columns), then $\det B = -\det A$.
8. If B is a matrix obtained from A by multiplying one row (or column) by a nonzero constant $c \in F$, then $\det B = c \det A$.
9. If B is a matrix obtained from A by multiplying a row (or column) by an element in the field F and adding it to another row (or column), then $\det B = \det A$.
10. If A, B, and C differ only in the kth row (or column), and the kth row (or column) of C is the sum of the kth rows (or columns) of A and B, then $\det C = \det A + \det B$.
11. If A is a matrix with a row (or column) of zeros, then $\det A = 0$.
12. If A is a matrix with two identical rows (or columns), then $\det A = 0$.
13. Let B be a row echelon form of A obtained by Gaussian elimination, using k row interchange operations and adding multiples, from the field F, of one row to another (see Algorithm 1.3.1). Then $\det A = (-1)^k \det B = (-1)^k b_{11} b_{22} \cdots b_{nn}$.
14. $\det A^T = \det A$.
15. If $A \in \mathbb{C}^{n \times n}$, then $\det A^* = \overline{\det A}$.
16. $\det AB = \det A \det B$.
17. If $c \in F$, then $\det(cA) = c^n \det A$.
18. A is nonsingular, that is A^{-1} exists, if and only if $\det A \neq 0$.
19. If A is nonsingular, then $\det\left(A^{-1}\right) = \frac{1}{\det A}$.
20. If S is nonsingular, then $\det\left(S^{-1} A S\right) = \det A$.
21. [HJ85, p. 8] $\det A = \sum_{\sigma} \operatorname{sgn}\sigma\, a_{1\sigma(1)} a_{2\sigma(2)} \cdots a_{n\sigma(n)}$, where summation is over the $n!$ permutations, σ, of the n indices $\{1, 2, \dots, n\}$. The weight "sgnσ" is 1 when σ is even and -1 when σ is odd. (See Preliminaries for more information on permutations.)
22. [Mey00, p. 475] If $\mathbf{x}, \mathbf{y} \in F^n$, then $\det(I + \mathbf{x}\mathbf{y}^T) = 1 + \mathbf{y}^T \mathbf{x}$.
23. [Mey00, p. 475] If $\det A \neq 0$, and $\mathbf{x}, \mathbf{y} \in F^n$, then $\det(A + \mathbf{x}\mathbf{y}^T) = (\det A)(1 + \mathbf{y}^T A^{-1} \mathbf{x})$.
24. [FIS89, p. 219] Let T be a linear operator on a finite dimensional vector space V. Let $\mathcal{B}$ and $\mathcal{B}'$ be bases for V. Then $\det(T) = \det\left([T]_{\mathcal{B}}\right) = \det\left([T]_{\mathcal{B}'}\right)$.
25. [FIS89, p. 220] Let T be a linear operator on a finite dimensional vector space V. Then T is invertible if and only if $\det(T) \neq 0$.
26. [FIS89, p. 220] Let T be an invertible linear operator on a finite dimensional vector space V. Then $\det(T^{-1}) = \frac{1}{\det(T)}$.
27. [FIS89, p. 220] Let T and U be linear operators on a finite dimensional vector space V. Then $\det(TU) = \det(T) \cdot \det(U)$.

Examples:

1. Let $A = \begin{bmatrix} 3 & -2 & 4 \\ 2 & 5 & -6 \\ -3 & 1 & 5 \end{bmatrix}$. Expanding the determinant of A along the second column: $\det A = 2 \cdot \det \begin{bmatrix} 2 & -6 \\ -3 & 5 \end{bmatrix} + 5 \cdot \det \begin{bmatrix} 3 & 4 \\ -3 & 5 \end{bmatrix} - \det \begin{bmatrix} 3 & 4 \\ 2 & -6 \end{bmatrix} = 2 \cdot (-8) + 5 \cdot 27 + 26 = 145.$
2. Let $A = \begin{bmatrix} -1 & 3 & -2 & 4 \\ 2 & 5 & 8 & 1 \\ 7 & -4 & 0 & -6 \\ 0 & 3 & 1 & 5 \end{bmatrix}$. Expanding the determinant of A along the third row: $\det A =$

$$7 \cdot \det \begin{bmatrix} 3 & -2 & 4 \\ 5 & 8 & 1 \\ 3 & 1 & 5 \end{bmatrix} + 4 \cdot \det \begin{bmatrix} -1 & -2 & 4 \\ 2 & 8 & 1 \\ 0 & 1 & 5 \end{bmatrix} + 6 \cdot \det \begin{bmatrix} -1 & 3 & -2 \\ 2 & 5 & 8 \\ 0 & 3 & 1 \end{bmatrix} = 557.$$

3. Let $F = \mathbb{Z}_5, A = \begin{bmatrix} 3 & 1 & 1 \\ 2 & 4 & 2 \\ 4 & 4 & 1 \end{bmatrix} \in F^{3\times 3}, \mathbf{x} = \begin{bmatrix} 1 \\ 2 \\ 4 \end{bmatrix}, \mathbf{y} = \begin{bmatrix} 0 \\ 1 \\ 3 \end{bmatrix} \in F^3$. Then $\det A = 1$, $\det\left(A + \mathbf{x}\mathbf{y}^T\right) = \det\left(\begin{bmatrix} 3 & 1 & 1 \\ 2 & 4 & 2 \\ 4 & 4 & 1 \end{bmatrix} + \begin{bmatrix} 0 & 1 & 3 \\ 0 & 2 & 1 \\ 0 & 4 & 2 \end{bmatrix}\right) = \det \begin{bmatrix} 3 & 2 & 4 \\ 2 & 1 & 3 \\ 4 & 3 & 3 \end{bmatrix} = 2$, and $1+\mathbf{y}^T A^{-1}\mathbf{x} = 1 + \begin{bmatrix} 0 & 1 & 3 \end{bmatrix} \begin{bmatrix} 1 & 3 & 3 \\ 1 & 4 & 1 \\ 2 & 2 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 2 \\ 4 \end{bmatrix} = 2.$

4. Let $T : \mathbb{R}^2 \to \mathbb{R}^2$ defined by $T\left(\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}\right) = \begin{bmatrix} 2x_1 - 3x_2 \\ x_1 + 6x_2 \end{bmatrix}$. With $\mathcal{B} = \left\{\begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right\}$, then $\det\left([T]_{\mathcal{B}}\right) = \det \begin{bmatrix} 2 & -3 \\ 1 & 6 \end{bmatrix} = 15$. Now let $\mathcal{B}' = \left\{\begin{bmatrix} 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right\}$. Then $\det\left([T]_{\mathcal{B}'}\right) = \det \begin{bmatrix} 7 & 1 \\ -8 & 1 \end{bmatrix} = 15$.

Applications:

1. (Cramer's Rule) If $A \in F^{n\times n}$ is nonsingular, then the equation $A\mathbf{x} = \mathbf{b}$, where $\mathbf{x}, \mathbf{b} \in F^n$, has the unique solution $\mathbf{s} = \begin{bmatrix} s_1 \\ s_2 \\ \vdots \\ s_n \end{bmatrix}$, where $s_i = \frac{\det A_i}{\det A}$ and A_i is the matrix obtained from A by replacing the ith column with $\mathbf{b}$.

2. [FB90, pp. 220–235] (Volume) Let $\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_n$ be linearly independent vectors in $\mathbb{R}^m$. The volume, V, of the n-dimensional solid in $\mathbb{R}^m$, defined by $S = \{\sum_{i=1}^n t_i \mathbf{a}_i, 0 \le t_i \le 1, i = 1, 2, \dots, n\}$, is given by $V = \sqrt{\det\left(A^T A\right)}$, where A is the matrix whose ith column is the vector $\mathbf{a}_i$.

   Let $m \ge n$ and $T : \mathbb{R}^n \to \mathbb{R}^m$ be a linear transformation whose standard matrix representation is the $m \times n$ matrix A. Let S be a region in $\mathbb{R}^n$ of volume V_S. Then the volume of the image of S under the transformation T is $V_{T(S)} = \sqrt{\det\left(A^T A\right)} \cdot V_S$.

3. [MH93, pp. 397–398] (Implicit Function Theorem) Let $X \subset \mathbb{R}^n \times \mathbb{R}^m$ be an open set, and let $F : X \to \mathbb{R}^m$ be a function of class C^k (F has k continuous derivatives, $k \ge 1$). For $(x, y) \in X$ let $F(x, y) = (f_1(x, y), \dots, f_m(x, y))$, and suppose $(x_0, y_0) \in X$ with $F(x_0, y_0) = 0$. If the **Jacobian Determinant**

$$\frac{\partial(f_1, \dots, f_m)}{\partial(y_1, \dots, y_m)} = \det \begin{bmatrix} \frac{\partial f_1}{\partial y_1} & \frac{\partial f_1}{\partial y_2} & \cdots & \frac{\partial f_1}{\partial y_m} \\ \frac{\partial f_2}{\partial y_1} & \frac{\partial f_2}{\partial y_2} & \cdots & \frac{\partial f_2}{\partial y_m} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial f_m}{\partial y_1} & \frac{\partial f_m}{\partial y_2} & \cdots & \frac{\partial f_m}{\partial y_m} \end{bmatrix}$$

   is not zero at (x_0, y_0), then there are an open neighborhood $U \subset \mathbb{R}^n$ of x_0, a neighborhood $V \subset \mathbb{R}^m$ of y_0, and a unique function $f : U \to V$ such that $F(x, f(x)) = 0$ for all $x \in U$.

4. [Mey00, p. 486] (Vandermonde Determinant)
$$\det\begin{bmatrix} 1 & 1 & \cdots & 1 \\ x_1 & x_2 & \cdots & x_n \\ x_1^2 & x_2^2 & \cdots & x_n^2 \\ \vdots & \vdots & \ddots & \vdots \\ x_1^{n-1} & x_2^{n-1} & \cdots & x_n^{n-1} \end{bmatrix} = \prod_{1\le i<j\le n}(x_j - x_i).$$
5. [Uhl02, pp. 247–248] (Wronskian) Let $f_1, f_2, \ldots, f_n$ be $n-1$ times differentiable functions of the real variable x. The determinant
$$W(f_1, f_2, \ldots, f_n)(x) = \det\begin{bmatrix} f_1(x) & f_2(x) & \cdots & f_n(x) \\ f_1'(x) & f_2'(x) & \cdots & f_n'(x) \\ \vdots & \vdots & \ddots & \vdots \\ f_1^{(n-1)}(x) & f_2^{(n-1)}(x) & \cdots & f_n^{(n-1)}(x) \end{bmatrix}$$
is called the **Wronskian** of $f_1, f_2, \ldots, f_n$. If $W(f_1, f_2, \ldots, f_n)(x) \neq 0$ for some $x \in \mathbb{R}$, then the functions $f_1, f_2, \ldots, f_n$ are linearly independent.

4.2 Determinants: Advanced Results

Definitions:

A **principal minor** is the determinant of a principal submatrix. (See Section 1.2.)

A **leading principal minor** is the determinant of a leading principal submatrix.

The sum of all the $k \times k$ principal minors of A is denoted $S_k(A)$.

The k**th compound matrix** of $A \in F^{m\times n}$ is the $\binom{m}{k} \times \binom{n}{k}$ matrix $A^{(k)}$ whose entries are the $k \times k$ minors of A. If α and γ are two sets of k row indices, and β and δ are two sets of k column indices, the minors $A[\alpha, \beta]$ and $A[\alpha, \delta]$ are placed in the same row of $A^{(k)}$, and the minors $A[\alpha, \beta]$ and $A[\gamma, \beta]$ are placed in the same column of $A^{(k)}$. The priority of elements is decided by the lexicographical order of the row (column) indices.

The **adjugate** of $A \in F^{n\times n}$, $A = [a_{ij}]$, is the matrix adj $A = [c_{ji}] = [c_{ij}]^T$, where c_{ij} is the ijth-cofactor of a_{ij}.

The **cofactor of a** $k\times k$ **minor,** $\det A[\alpha, \beta]$, with $\alpha = \{i_1, i_2, \ldots, i_k\}$ and $\beta = \{j_1, j_2, \ldots, j_k\}$, $A \in F^{n\times n}$, is the signed minor $(-1)^{i_1+j_1+i_2+j_2+\cdots+i_k+j_k} \det A[\alpha^c, \beta^c]$.

The k**th adjugate compound** of $A \in F^{n\times n}$ is the $\binom{n}{k} \times \binom{n}{k}$ matrix $\mathrm{adj}^{(k)}A$ whose (i, j) entry is the cofactor, in A, of the $k \times k$ minor of A that is the (j, i) entry in $A^{(k)}$.

Let $\alpha \subseteq \{1, 2, \ldots, n\}$ and $A \in F^{n\times n}$ with $A[\alpha]$ nonsingular. The matrix
$$A/A[\alpha] = A[\alpha^c] - A[\alpha^c, \alpha]A[\alpha]^{-1}A[\alpha, \alpha^c]$$
is called the **Schur complement** of $A[\alpha]$.

Facts:

All the following facts except those with a specific reference can be found in [Gol07, pp. 199–228], [Lay12, pp. 163–187], or [Mey00, pp. 459–488].
Notation: A is a matrix in $F^{n\times n}$.

1. $A\,(\mathrm{adj}\ A) = (\mathrm{adj}\ A)\,A = (\det A)\,I_n$.
2. $\det(\mathrm{adj}\ A) = (\det A)^{n-1}$.
3. If $\det A \neq 0$, then adj A is nonsingular, and $(\mathrm{adj}\ A)^{-1} = (\det A)^{-1}A$.

4. [Zha99, p. 36] Let M be a square matrix partitioned as $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$. If $AC = CA$, then $\det M = \det(AD - CB)$.
5. [Mar90] $\det(A+B) = \sum_{r=0}^{n} \sum_{\alpha,\beta} (-1)^{s(\alpha)+s(\beta)} \det(A[\alpha,\beta]) \det(B[\alpha^c, \beta^c])$, where the interior sum is taken over all strictly increasing integer sequences $\alpha, \beta \subseteq \{1, 2, \ldots, n\}$ of length r, $s(\alpha)$ is the sum of the integers in α. Note that for a matrix M, $\det M[\emptyset] = 1$, and that a sum over the empty set is defined to be zero.
6. [Ait56, pp. 45–48] (Method of Condensation) Let $A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \cdots & a_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & a_{nn} \end{bmatrix}$, and assume without loss of generality that $a_{11} \neq 0$, otherwise a nonzero element can be brought to the $(1,1)$ position by interchanging two rows, which will change the sign of the determinant. Multiply all the rows of A except the first by a_{11}. For $i = 2, 3, \ldots, n$, perform the row operations: replace row i with row $i - a_{i1} \cdot$ row 1. Thus,
$$a_{11}^{n-1} \det A = \det \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ 0 & a_{11}a_{22} - a_{21}a_{12} & a_{11}a_{23} - a_{21}a_{13} & \cdots & a_{11}a_{2n} - a_{21}a_{1n} \\ 0 & a_{11}a_{32} - a_{31}a_{12} & a_{11}a_{33} - a_{31}a_{13} & \cdots & a_{11}a_{3n} - a_{31}a_{1n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & a_{11}a_{n2} - a_{n1}a_{12} & a_{11}a_{n3} - a_{n1}a_{12} & \cdots & a_{11}a_{nn} - a_{n1}a_{1n} \end{bmatrix}.$$
So, $$\det A = \frac{1}{a_{11}^{n-2}} \cdot \det \begin{bmatrix} \det \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} & \det \begin{bmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{bmatrix} & \cdots & \det \begin{bmatrix} a_{11} & a_{1n} \\ a_{21} & a_{2n} \end{bmatrix} \\ \det \begin{bmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{bmatrix} & \det \begin{bmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{bmatrix} & \cdots & \det \begin{bmatrix} a_{11} & a_{1n} \\ a_{31} & a_{32} \end{bmatrix} \\ \vdots & \vdots & \ddots & \vdots \\ \det \begin{bmatrix} a_{11} & a_{12} \\ a_{n1} & a_{n2} \end{bmatrix} & \det \begin{bmatrix} a_{11} & a_{12} \\ a_{n1} & a_{n3} \end{bmatrix} & \cdots & \det \begin{bmatrix} a_{11} & a_{1n} \\ a_{n1} & a_{nn} \end{bmatrix} \end{bmatrix}.$$
7. [Ait56, pp. 91–92] $A^{(k)}(\mathrm{adj}^{(k)} A) = (\mathrm{adj}^{(k)} A) A^{(k)} = (\det A) I_{\binom{n}{k}}$.
8. [Ait56, p. 92] $\det\left(A^{(k)}\right) = \det\left(A^{r}\right)$, where $r = \begin{pmatrix} n-1 \\ k-1 \end{pmatrix}$.
9. [Ait56, p. 92] $\det\left(A^{(n-k)}\right) = \det(\mathrm{adj}^{(k)} A)$.
10. [HJ91, p. 249] If $A \in F^{n \times n}$, $B \in F^{m \times m}$, then $\det(A \otimes B) = (\det A)^m (\det B)^n$. (See Section 11.4 for the definition of $A \otimes B$.)
11. [Uhl02, pp. 241–243] The determinant is the unique normalized, alternating, and multilinear function $d : F^{n \times n} \to F$. That is, $d(I_n) = 1$, $d(A) = -d(A')$, where A' denotes the matrix obtained from A, by interchanging two rows, and d is linear in each row of A, if the remaining rows of A are held fixed.
12. [HJ85, p. 22] (Cauchy–Binet) Let $A \in F^{n \times k}, B \in F^{k \times n}$, and $C = AB$. Then
$$\det C[\alpha, \beta] = \sum_{\gamma} \det A[\alpha, \gamma] \det B[\gamma, \beta],$$
where $\alpha \subseteq \{1, 2, \ldots, m\}$, $\beta \subseteq \{1, 2, \ldots, n\}$, with $|\alpha| = |\beta| = r$, $1 \leq r \leq \min\{m, k, n\}$, and the sum is taken over all sets $\gamma \subseteq \{1, 2, \ldots, k\}$ with $|\gamma| = r$.
13. [HJ85, pp. 21–22] (Schur Complement). Let $A[\alpha]$ be nonsingular. Then
$$\det A = \det A[\alpha] \det\left(A[\alpha^c] - A\left[\alpha^c, \alpha\right] A[\alpha]^{-1} A\left[\alpha, \alpha^c\right]\right).$$

14. [HJ85, p. 21] (Jacobi's Theorem) Let A be nonsingular and let $\alpha, \beta \subseteq \{1, 2, \ldots, n\}$, with $|\alpha| = |\beta|$. Then
$$\det A^{-1}[\alpha^c, \beta^c] = (-1)^{\left(\sum_{i\in\alpha} i + \sum_{j\in\beta} j\right)} \frac{\det A[\beta, \alpha]}{\det A}.$$
In particular, if $\alpha = \beta$. Then $\det A^{-1}[\alpha^c] = \frac{\det A[\alpha]}{\det A}$.
15. [HJ85, p. 22] (Sylvester's Identity) Let $\alpha \subseteq \{1, 2, \ldots, n\}$ with $|\alpha| = k$, and $i, j \in \{1, 2, \ldots, n\}$, with $i, j \notin \alpha$. For $A \in F^{n\times n}$, let $B = [b_{ij}] \in F^{(n-k)\times(n-k)}$ be defined by $b_{ij} = \det A\left[\alpha \cup \{i\}, \alpha \cup \{j\}\right]$. Then
$$\det B = (\det A[\alpha])^{n-k-1} \det A.$$

Examples:

1. (Sums of principal minors) Let $A = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & -3 & 2 \\ 0 & -1 & -2 & -4 \end{bmatrix}$. Clearly, $S_1(A) = \text{tr } A = -5$. From the Laplace expansion on the first column and $\det A[\{2, 3, 4\}] = 13$, it follows that $S_4(A) = \det A = 13$. $S_3(A) = 23$ because $\det A[\{1, 2, 3\}] = \det \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -3 \end{bmatrix} = -3$, $\det A[\{1, 2, 4\}] = \det \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & -1 & -4 \end{bmatrix} = -3$, $\det A[\{1, 3, 4\}] = \det \begin{bmatrix} 1 & 0 & 0 \\ 0 & -3 & 2 \\ 0 & -2 & -4 \end{bmatrix} = 16$, and $\det A[\{2, 3, 4\}] = \det \begin{bmatrix} 1 & 0 & 1 \\ 0 & -3 & 2 \\ -1 & -2 & -4 \end{bmatrix} = 13$.

2. (Determinant of a sum) Let $A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 0 & -4 \\ -1 & 1 & 0 \end{bmatrix}$, and $B = \begin{bmatrix} 1 & 2 & -3 \\ 1 & -7 & 0 \\ -2 & 1 & 5 \end{bmatrix}$, then
$\sum_{r=0}^{n} \sum_{\alpha,\beta} (-1)^{s(\alpha)+s(\beta)} \det(A[\alpha, \beta]) \det(B[\alpha^c, \beta^c]) =$
$\det B + ((-1)^2 \det A[\{1\}] \det B[\{2, 3\}] + (-1)^3 \det A[\{1\}, \{2\}] \det B[\{2, 3\}, \{1, 3\}]+$
$(-1)^4 \det A[\{1\}, \{3\}] \det B[\{2, 3\}, \{1, 2\}] + (-1)^3 \det A[\{2\}, \{1\}] \det B[\{1, 3\}, \{2, 3\}]+$
$(-1)^4 \det A[\{2\}] \det B[\{1, 3\}] + (-1)^5 \det A[\{2\}, \{3\}] \det B[\{1, 3\}, \{1, 2\}]+$
$(-1)^4 \det A[\{3\}, \{1\}] \det B[\{1, 2\}, \{2, 3\}] + (-1)^5 \det A\{[3\}, \{2\}] \det B[\{1, 2\}, \{1, 3\}]+$
$(-1)^6 \det A[\{3\}] \det B[\{1, 2\}]) + ((-1)^6 \det A[\{1, 2\}] \det B[\{3\}]+$
$(-1)^7 \det A[\{1, 2\}, \{1, 3\}] \det B[\{3\}, \{2\}] + (-1)^8 \det A[\{1, 2\}, \{2, 3\}] \det B[\{3\}, \{1\}]+$
$(-1)^7 \det A[\{1, 3\}, \{1, 2\}] \det B[\{2\}, \{3\}] + (-1)^8 \det A[\{1, 3\}] \det B[\{2\}]+$
$(-1)^9 \det A[\{1, 3\}, \{2, 3\}] \det B[\{2\}, \{1\}] + (-1)^8 \det A[\{2, 3\}, \{1, 2\}] \det B[\{1\}, \{3\}]+$
$(-1)^9 \det A[\{2, 3\}, \{1, 3\}] \det B[\{1\}, \{2\}] + (-1)^{10} \det A[\{2, 3\}] \det B[\{1\}]) + \det A =$
$-6 - 28 + 11 + 9 = -14$. Also, $A + B = \begin{bmatrix} 2 & 2 & -2 \\ 2 & -7 & -4 \\ -3 & 2 & 5 \end{bmatrix}$, and $\det(A + B) = -14$.

3. (kth compound and kth adjugate compound) Let $A = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 4 \\ 1 & 1 & 0 & 1 \\ 1 & 4 & 0 & 1 \end{bmatrix}$. Then $\det A = 9$,

$$A^{(2)} = \begin{bmatrix} -1 & 0 & 3 & 1 & 4 & 3 \\ 0 & -1 & 0 & -1 & 0 & 1 \\ 3 & -1 & 0 & -4 & -3 & 1 \\ 1 & -1 & -3 & -1 & -4 & 1 \\ 4 & -1 & -3 & -4 & -16 & 1 \\ 3 & 0 & 0 & 0 & -3 & 0 \end{bmatrix}, \quad \mathrm{adj}^{(2)} A = \begin{bmatrix} 0 & -1 & 1 & 1 & -1 & 3 \\ 3 & -16 & 4 & 3 & 0 & -4 \\ 0 & 4 & -1 & -4 & 1 & 1 \\ 0 & 3 & -3 & 0 & 0 & 3 \\ 0 & -1 & 1 & 1 & -1 & 0 \\ 3 & -4 & 1 & 3 & 0 & -1 \end{bmatrix},$$

$A^{(2)}\mathrm{adj}^{(2)} A = \mathrm{adj}^{(2)} A A^{(2)} = 9I$, and $\det\left(A^{(2)}\right) = 729 = \det\left(\mathrm{adj}^{(2)} A\right)$.

4. (Cauchy–Binet) Let $A = \begin{bmatrix} -1 & 3 & -1 \\ 2 & 0 & 0 \\ i & -4 & 0 \\ 0 & 1+i & 1 \end{bmatrix}$, $B = \begin{bmatrix} 3 & 2 & -3 & 0 \\ 0 & -4 & 4 & 3i \\ 7 & -6i & 5 & 4 \end{bmatrix}$, and $C = AB$.

   Then $\det C[\{2,4\},\{2,3\}] =$
   $\det A[\{2,4\},\{1,2\}] \det B[\{1,2\},\{2,3\}] +$
   $\det A[\{2,4\},\{1,3\}] \det B[\{1,3\},\{2,3\}] +$
   $\det A[\{2,4\},\{2,3\}] \det B[\{2,3\},\{2,3\}] = 12 - 44i$.

5. (Schur Complement) Let $A = \begin{bmatrix} a & \mathbf{b}^* \\ \mathbf{b} & C \end{bmatrix}$, where $a \in \mathbb{C}$, $\mathbf{b} \in \mathbb{C}^{n-1}$, and $C \in \mathbb{C}^{(n-1)\times(n-1)}$. If C is nonsingular, then $\det A = (a - \mathbf{b}^* C^{-1}\mathbf{b}) \det C$. If $a \neq 0$, then $\det A = a \det\left(C - \frac{1}{a}\mathbf{b}\mathbf{b}^*\right)$.

6. (Jacobi's Theorem) Let $A = \begin{bmatrix} 1 & -2 & 0 \\ 3 & 4 & 0 \\ -1 & 0 & 5 \end{bmatrix}$ and $\alpha = \{2\} = \beta$. By Jacobi's formula, $\det A^{-1}(2) = \frac{\det A[2]}{\det A} = \frac{4}{50} = \frac{2}{25}$. This can be readily verified by computing $A^{-1} = \begin{bmatrix} \frac{2}{5} & \frac{1}{5} & 0 \\ -\frac{3}{10} & \frac{1}{10} & 0 \\ \frac{2}{25} & \frac{1}{25} & \frac{1}{5} \end{bmatrix}$, and verifying $\det A^{-1}[\{1,3\}] = \frac{2}{25}$.

7. (Sylvester's Identity) Let $A = \begin{bmatrix} -7 & i & -3 \\ -i & -2 & 1+4i \\ -3 & 1-4i & 5 \end{bmatrix}$ and $\alpha = \{1\}$. Define $B \in \mathbb{C}^{2\times 2}$, with entries $b_{11} = \det A[\{1,2\}] = 13$, $b_{12} = \det A[\{1,2\},\{1,3\}] = -7 - 31i$, $b_{21} = \det A[\{1,3\},\{1,2\}] = -7 + 31i$, $b_{22} = \det A[\{1,3\}] = -44$. Then $-1582 = \det B = (\det A[\{1\}]) \det A = (-7) \det A$, so $\det A = 226$.

4.3 The Pfaffian

Definitions:

A **matching** in a graph G is a set of edges $\{i_1, j_1\}, ..., \{i_k, j_k\}$ such that all the vertices are distinct.

A **perfect matching** in a graph G of even order is a matching that includes all vertices of G.

The **graph of an $n \times n$ symmetric or skew-symmetric matrix $A = [a_{ij}]$ over a field F,** denoted $G(A)$, is the graph with vertices $\{1, \ldots, n\}$ and edges $\{\{i,j\} : a_{ij} \neq 0, 1 \leq i < j \leq n\}$.

Let A be skew-symmetric, and $L = \{\{i_1, i_2\}, \ldots, \{i_{n-1}, i_n\}\}$ be a perfect matching in $G(A)$, ordered so that $i_1 < i_2, i_3 < i_4, \ldots, i_{n-1} < i_n$ and $i_1 < i_3 < \cdots < i_{n-1}$. Let π_L be the permutation of $\{1, \ldots, n\}$ that maps k to i_k. The **weight of the perfect matching** L is $\mathrm{wt}_A(L) = \mathrm{sgn}(\pi_L) a_{i_1,i_2} \ldots a_{i_{n-1},i_n}$, where $\mathrm{sgn}(\pi)$ is the sign of the permutation π.

Let $\mathcal{M}_G$ be the set of all perfect matchings in G. The **pfaffian** of A is $\mathrm{pf}\, A = \sum_{L \in \mathcal{M}_{G(A)}} \mathrm{wt}_A(L)$, where the sum over the empty set is 0.

Facts:

All the following facts can be found in [BR91, pp. 317–324], or [God93, pp. 113–129]. Notation: F is a field, $\operatorname{char} F \neq 2$, $A \in F^{n\times n}$, and $A^T = -A$.

1. [BR91, p. 318] The pfaffian of A is a linear form in the indeterminates a_{ij} that appear in A and is homogeneous of degree $\frac{n}{2}$.
2. [BR91, p. 319] (Caley) If A has even order, then $\det A = (\operatorname{pf} A)^2$.
3. [God93, p. 117] $\operatorname{pf} A = \sum_{i=2}^{n} (-1)^{1+i} a_{1i} \operatorname{pf} A(\{i,j\})$.
4. [God93, p. 118] (Halton) $(\operatorname{pf} A)(\operatorname{pf} A(\{i,j\})) = -\det A(\{i\},\{j\})$ if $i < j$.
5. [God93, p. 118] If H_A satisfies $AH_A = (\operatorname{pf} A)\, I$, then H_A is skew-symmetric and its ijth entry is $\operatorname{pf} A(\{i,j\})$ if $i > j$ and $-\operatorname{pf} A(\{i,j\})$ if $i < j$.
6. [God93, p. 125] If $B \in F^{n\times n}$, then $\operatorname{pf}\left(B^T A B\right) = \det B \operatorname{pf} A$.

Examples:

For the following, let $A = \begin{bmatrix} 0 & a_{12} & 0 & a_{14} & 0 & 0 \\ -a_{12} & 0 & a_{23} & 0 & a_{25} & 0 \\ 0 & -a_{23} & 0 & 0 & 0 & a_{36} \\ -a_{14} & 0 & 0 & 0 & a_{45} & 0 \\ 0 & -a_{25} & 0 & -a_{45} & 0 & a_{56} \\ 0 & 0 & -a_{36} & 0 & -a_{56} & 0 \end{bmatrix}$, and $B = \begin{bmatrix} 1 & 0 & -1 & 0 & 0 & 0 \\ -1 & 0 & 2 & 1 & 0 & 0 \\ 0 & -2 & 0 & 0 & 0 & 3 \\ -1 & 0 & 0 & -1 & 4 & 0 \\ 0 & -1 & 0 & -1 & 0 & 1 \\ 0 & 0 & 1 & 0 & -2 & -3 \end{bmatrix}$.

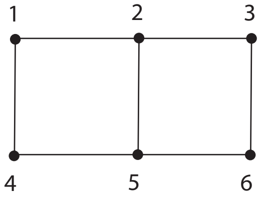

FIGURE 4.1 The graph $G(A)$ for matrix A.

1. $G(A)$ has three perfect matchings with the desired ordering: $\{\{1,2\},\{3,6\},\{4,5\}\}$, $\{\{1,4\},\{2,3\},\{5,6\}\}$, $\{\{1,4\}, \{2,5\},\{3,6\}\}$. Thus, $\operatorname{pf} A = a_{12}a_{36}a_{45} + a_{14}a_{23}a_{56} - a_{14}a_{25}a_{36}$, and $\det A = (a_{12}a_{36}a_{45} + a_{14}a_{23}a_{56} - a_{14}a_{25}a_{36})^2$.
2. This illustrates Fact 3 (expansion along the first row).
   $\operatorname{pf} A = a_{12} \operatorname{pf} A(\{1,2\}) + a_{14} \operatorname{pf} A(\{1,4\}) = a_{12}\,(a_{36}a_{45}) + a_{14}\,(a_{23}a_{56} - a_{25}a_{36})$.
3. $$\begin{aligned}(\operatorname{pf} A)(\operatorname{pf} A(\{1,4\})) &= (a_{12}a_{36}a_{45} + a_{14}a_{23}a_{56} - a_{14}a_{25}a_{36})\,(a_{23}a_{56} - a_{25}a_{36}) \\ &= -\det A(\{1\},\{4\}).\end{aligned}$$
4. $(\det B)(\operatorname{pf} A) = -20\,(a_{12}a_{36}a_{45} + a_{14}a_{23}a_{56} - a_{14}a_{25}a_{36}) = \operatorname{pf}\left(B^T A B\right)$.

4.4 Eigenvalues and Eigenvectors

Definitions:

An element $\lambda \in F$ is an **eigenvalue** of a matrix $A \in F^{n\times n}$ if there exists a nonzero vector $\mathbf{x} \in F^n$ such that $A\mathbf{x} = \lambda\mathbf{x}$. The vector $\mathbf{x}$ is said to be an **eigenvector** of A corresponding to the eigenvalue λ. A nonzero row vector $\mathbf{y}$ is a **left eigenvector** of A, corresponding to the eigenvalue λ, if $\mathbf{y}A = \lambda\mathbf{y}$.

The **characteristic polynomial** of A is given by $p_A(x) = \det(xI - A)$.

The **algebraic multiplicity**, $\alpha_A(\lambda)$ (or $\alpha(\lambda)$ if A is clear), is the number of times the eigenvalue occurs as a root in the characteristic polynomial of A.

The **spectrum** of A, $\sigma(A)$, is the multiset of all eigenvalues of A, with eigenvalue λ appearing $\alpha(\lambda)$ times in $\sigma(A)$.

The **spectral radius** of $A \in \mathbb{C}^{n\times n}$ is $\rho(A) = \max\{|\lambda| : \lambda \in \sigma(A)\}$.

Let $p(x) = c_nx^n + c_{n-1}x^{n-1} + \cdots + c_2x^2 + c_1x + c_0$ be a polynomial with coefficients in F. Then $p(A) = c_nA^n + c_{n-1}A^{n-1} + \cdots + c_2A^2 + c_1A + c_0I$.

The **minimal polynomial** of A, $q_A(x)$, is the unique monic polynomial of least degree for which $q_A(A) = 0$.

The vector space $\ker(A - \lambda I)$, for $\lambda \in \sigma(A)$, is the **eigenspace** of A corresponding to λ, and is denoted by $E_\lambda(A)$.

The **geometric multiplicity**, $\gamma(\lambda)$, of an eigenvalue λ is the dimension of the eigenspace $E_\lambda(A)$.

An eigenvalue λ is **simple** if $\alpha(\lambda) = 1$.

An eigenvalue λ is **semisimple** if $\alpha(\lambda) = \gamma(\lambda)$.

For $F = \mathbb{C}$ or any other algebraically closed field, a matrix $A \in F^{n\times n}$ is **nonderogatory** if $\gamma(\lambda) = 1$ for all $\lambda \in \sigma(A)$, otherwise A is **derogatory**. Over an arbitrary field F, a matrix is nonderogatory (derogatory) if it is nonderogatory (derogatory) over the algebraic closure of F.

For $F = \mathbb{C}$ or any other algebraically closed field, a matrix $A \in F^{n\times n}$ is **nondefective** if every eigenvalue of A is semisimple, otherwise A is **defective**. Over an arbitrary field F, a matrix is nondefective (defective) if it is nondefective (defective) over the algebraic closure of F.

A matrix $A \in F^{n\times n}$ is **diagonalizable** if there exists a nonsingular matrix $B \in F^{n\times n}$, such that $A = BDB^{-1}$ for some diagonal matrix $D \in F^{n\times n}$.

For a monic polynomial $p(x) = x^n + c_{n-1}x^{n-1} + \cdots + c_2x^2 + c_1x + c_0$ with coefficients in F, the $n \times n$ matrix $C(p) = \begin{bmatrix} 0 & 0 & 0 & \cdots & 0 & -c_0 \\ 1 & 0 & 0 & \cdots & 0 & -c_1 \\ 0 & 1 & 0 & \cdots & 0 & -c_2 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & -c_{n-1} \end{bmatrix}$ is called the **companion matrix** of $p(x)$.

Let T be a linear operator on a finite dimensional vector space, V, over a field F. An element $\lambda \in F$ is an **eigenvalue** of T if there exists a nonzero vector $\mathbf{v} \in V$ such that $T(\mathbf{v}) = \lambda\mathbf{v}$. The vector $\mathbf{v}$ is said to be an **eigenvector** of T corresponding to the eigenvalue λ.

For a linear operator, T, on a finite dimensional vector space, V, with a basis, $\mathcal{B}$, the **characteristic polynomial** of T is given by $p_T(x) = p_{[T]_\mathcal{B}}(x)$.

A linear operator T on a finite dimensional vector space, V, is **diagonalizable** if there exists a basis, $\mathcal{B}$, for V such that $[T]_\mathcal{B}$ is diagonalizable.

Facts:

These facts are grouped into the following categories: Eigenvalues and Eigenvectors, Diagonalization, Polynomials, and Other Facts. All the following facts, except those with a specific reference, can be found in [Gol07, pp. 229–266], [Lay12, pp. 265–301], [Lew91, 116–140], or [Mey00, pp. 489–660].

Notation: A is a matrix in $F^{n\times n}$.

Eigenvalues and Eigenvectors

1. [Mey00, p. 492] $\lambda \in \sigma(A)$ if and only if $p_A(\lambda) = 0$.
2. [Mey00, p. 511] For each eigenvalue λ of a matrix A, $1 \leq \gamma(\lambda) \leq \alpha(\lambda)$.
3. [Mey00, p. 510] A simple eigenvalue is semisimple.
4. For any F, $|\sigma(A)| \leq n$. If $F = \mathbb{C}$ or any algebraically closed field, then $|\sigma(A)| = n$.
5. If $F = \mathbb{C}$ or any algebraically closed field, then $\det A = \prod_{i=1}^n \lambda_i, \lambda_i \in \sigma(A)$.

6. If $F = \mathbb{C}$ or any algebraically closed field, then tr $A = \sum_{i=1}^{n} \lambda_i, \lambda_i \in \sigma(A)$.
7. For $A \in \mathbb{C}^{n\times n}$, $\lambda \in \sigma(A)$ if and only if $\bar{\lambda} \in \sigma(A^*)$.
8. [Mey00, p. 492] For $A \in \mathbb{R}^{n\times n}$, viewing $A \in \mathbb{C}^{n\times n}$, $\lambda \in \sigma(A)$ if and only if $\bar{\lambda} \in \sigma(A)$.
9. A and A^T have the same eigenvalues with same algebraic multiplicities.
10. If $A = [a_{ij}]$ is triangular, then $\sigma(A) = \{a_{11}, a_{22}, \ldots, a_{nn}\}$.
11. If A has all row (column) sums equal to r, then r is an eigenvalue of A.
12. A is singular if and only if $\det A = 0$, if and only if $0 \in \sigma(A)$.
13. If A is nonsingular and λ is an eigenvalue of A of algebraic multiplicity $\alpha(\lambda)$, with corresponding eigenvector $\mathbf{x}$, then λ^{-1} is an eigenvalue of A^{-1} with algebraic multiplicity $\alpha(\lambda)$ and corresponding eigenvector $\mathbf{x}$.
14. [Mey00, pp. 511–512] Let $\lambda_1, \lambda_2, \ldots, \lambda_s$ be distinct eigenvalues of A. For each $i = 1, 2, \ldots, s$ let $\mathbf{x}_{i1}, \mathbf{x}_{i2}, \ldots, \mathbf{x}_{ir_i}$ be linearly independent eigenvectors corresponding to λ_i. Then the vectors $\mathbf{x}_{11}, \ldots, \mathbf{x}_{1r_1}, \mathbf{x}_{21}, \ldots, \mathbf{x}_{2r_2}, \ \ldots, \mathbf{x}_{s1}, \ldots, \mathbf{x}_{sr_s}$ are linearly independent.
15. [GV96, p. 323] For any matrix $A \in \mathbb{C}^{n\times n}$, the eigenvalues of A are continuous functions of the entries of A.
16. [GV96, p. 323] Let $A, E \in \mathbb{C}^{n\times n}$ and $\|E\|_2 = 1$. If λ is a simple eigenvalue of A and $A(\varepsilon) = A + \varepsilon E$, then in a neighborhood of the origin there exist differentiable functions $\lambda(\varepsilon)$ and $\mathbf{x}(\varepsilon)$ such that
$$A(\varepsilon)\mathbf{x}(\varepsilon) = \lambda(\varepsilon)\mathbf{x}(\varepsilon).$$
17. [FIS89, p. 221] Let T be a linear operator on a finite dimensional vector space V over a field F, with basis $\mathcal{B}$. Then $\lambda \in F$ is an eigenvalue of T if and only if λ is an eigenvalue of $[T]_{\mathcal{B}}$.
18. [FIS89, pp. 231–232] Let $\lambda_1, \lambda_2, \ldots, \lambda_s$ be distinct eigenvalues of the linear operator T, on a finite dimensional space V. For each $i = 1, 2, \ldots, s$ let $\mathbf{x}_{i1}, \mathbf{x}_{i2}, \ldots, \mathbf{x}_{ir_i}$ be linearly independent eigenvectors corresponding to λ_i. Then the vectors $\mathbf{x}_{11}, \ldots, \mathbf{x}_{1r_1}, \mathbf{x}_{21}, \ldots, \mathbf{x}_{2r_2}, \ldots, \mathbf{x}_{s1}, \ldots, \mathbf{x}_{sr_s}$ are linearly independent.
19. [FIS89, p. 222] Let T be a linear operator on a finite dimensional vector space V over a field F. Then $\lambda \in F$ is an eigenvalue of T if and only if $p_T(\lambda) = 0$.

Diagonalization

20. If $A \in \mathbb{C}^{n\times n}$ is Hermitian (e.g., $A \in \mathbb{R}^{n\times n}$ is symmetric), then A has real eigenvalues and A can be diagonalized. (See also Section 8.2.)
21. [Lew91, p. 136] Let $\lambda_1, \lambda_2, \ldots, \lambda_s$ be distinct eigenvalues of A. If $A \in F^{n\times n}$, where F is an algebraically closed field, then A is diagonalizable if and only if $\alpha(\lambda_i) = \gamma(\lambda_i)$ for $i = 1, 2, \ldots, s$, that is, if and only if A is nondefective. If $A \in \mathbb{R}^{n\times n}$, then A is diagonalizable by a nonsingular matrix $B \in \mathbb{R}^{n\times n}$ if and only if all the eigenvalues of A are real and $\alpha(\lambda_i) = \gamma(\lambda_i)$ for $i = 1, 2, \ldots, s$.
22. Method for Diagonalization of A over $\mathbb{C}$: This is a theoretical method using exact arithmetic and is undesirable in decimal arithmetic with rounding errors. See Chapter 56 for information on appropriate numerical methods.
    - Find the eigenvalues of A.
    - Find a basis $\mathbf{x}_{i1}, \ldots, \mathbf{x}_{ir_i}$ for $E_{\lambda_i}(A)$ for each of the distinct eigenvalues $\lambda_1, \ldots, \lambda_k$ of A.
    - If $r_1 + \cdots + r_k = n$, then let $B = [\mathbf{x}_{11} \ldots \mathbf{x}_{1r_1} \ldots \mathbf{x}_{k1} \ldots \mathbf{x}_{kr_k}]$. B is invertible and $D = B^{-1}AB$ is a diagonal matrix, whose diagonal entries are the eigenvalues of A, in the order that corresponds to the order of the columns of B. Else A is not diagonalizable.
23. A is diagonalizable if and only if A has n linearly independent eigenvectors.

24. If A has n distinct eigenvalues, then A is diagonalizable.
25. A is diagonalizable if and only if $q_A(x)$ can be factored into distinct linear factors.
26. If A is diagonalizable, then so are $A^T, A^k, k \in \mathbb{N}$.
27. If A is nonsingular and diagonalizable, then A^{-1} is diagonalizable.
28. If A is idempotent, then A is diagonalizable and $\sigma(A) \subseteq \{0, 1\}$.
29. If A is nilpotent, then $\sigma(A) = \{0\}$. If A is nilpotent and is not the zero matrix, then A is not diagonalizable.
30. [FIS89, p. 216] Let T be a linear operator on a finite dimensional vector space V with a basis $\mathcal{B}$. Then T is diagonalizable if and only if $[T]_{\mathcal{B}}$ is diagonalizable.
31. [FIS89, p. 217] A linear operator, T, on a finite dimensional vector space V over a field F is diagonalizable if and only if there exists a basis $\mathcal{B} = \{\mathbf{v}_1, \ldots, \mathbf{v}_n\}$ for V, and scalars $\lambda_1, \ldots, \lambda_n \in F$, such that $T(\mathbf{v}_i) = \lambda_i \mathbf{v}_i$, for $1 \leq i \leq n$.
32. [FIS89, p. 232] If a linear operator, T, on a vector space, V, of dimension n, has n distinct eigenvalues, then it is diagonalizable.
33. [FIS89, p. 233] The characteristic polynomial of a diagonalizable linear operator on a finite dimensional vector space can be factored into linear terms.

Polynomials

34. [HJ85, pp. 86–87] (Cayley–Hamilton Theorem) Let $p_A(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ be the characteristic polynomial of A. Then $p_A(A) = A^n + a_{n-1}A^{n-1} + \cdots + a_1 A + a_0 I_n = 0$.
35. [FIS89, pp. 284–285] (Cayley–Hamilton Theorem for a Linear Operator) Let $p_T(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ be the characteristic polynomial of a linear operator, T, on a finite dimensional vector space, V. Then $p_T(T) = T^n + a_{n-1}T^{n-1} + \cdots + a_1 T + a_0 I_n = T_0$, where T_0 is the zero linear operator on V.
36. $p_{A^T}(x) = p_A(x)$.
37. [Mey00, pp. 644–645] The minimal polynomial $q_A(x)$ of a matrix A is a factor of the characteristic polynomial $p_A(x)$ of A.
38. [Mey00, p. 644] The minimal polynomial $q_A(x)$ of A and the characteristic polynomial $p_A(x)$ of A are equal if and only if A is nonderogatory.
39. If λ is an eigenvalue of A associated with the eigenvector $\mathbf{x}$, then $p(\lambda)$ is an eigenvalue of the matrix $p(A)$ associated with the eigenvector $\mathbf{x}$, where $p(x)$ is a polynomial with coefficients in F.
40. [Gol07, p. 243] If B is nonsingular, $p_A(x) = p_{B^{-1}AB}(x)$; therefore, A and $B^{-1}AB$ have the same eigenvalues.
41. Let $p_A(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ be the characteristic polynomial of A. If $|\sigma(A)| = n$, then $a_k = (-1)^{n-k} S_{n-k}(\lambda_1, \ldots, \lambda_n), k = 0, 1, \ldots, n-1$, where $S_k(\lambda_1, \ldots, \lambda_n)$ is the kth symmetric function of the eigenvalues of A.
42. [Mey00, p. 494] Let $p_A(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ be the characteristic polynomial of A. Then $a_k = (-1)^{n-k} S_{n-k}(A), k = 0, 1, \ldots, n-1$.
43. If $|\sigma(A)| = n$, then $S_k(A) = S_k(\lambda_1, \ldots, \lambda_n)$.
44. [Mey00, p. 648] If $C(p)$ is the companion matrix of the polynomial $p(x)$, then $p(x) = p_{C(p)}(x) = q_{C(p)}(x)$.
45. [HJ85, p. 135] If $|\sigma(A)| = n$, A is nonderogatory, and if B commutes with A, then there exists a polynomial $f(x)$ of degree less than n such that $B = f(A)$.

Other Facts

46. [Gol07, p. 235] If A is nonsingular and λ is an eigenvalue of A of algebraic multiplicity $\alpha(\lambda)$, with corresponding eigenvector $\mathbf{x}$, then $\det(A)\lambda^{-1}$ is an eigenvalue of adj A with algebraic multiplicity $\alpha(\lambda)$ and corresponding eigenvector $\mathbf{x}$.
47. [Gol07, p. 235] If $\lambda \in \sigma(A)$, with $\gamma(\lambda) = 1$, then any nonzero column of adj $(A - \lambda I)$ is an eigenvector of A corresponding to λ.

48. [HJ85, p. 51] If $AB = BA$, then A and B have a common eigenvector.
49. [HJ85, p. 53] If $A \in F^{m\times n}$ and $B \in F^{n\times m}$ with $m \leq n$. Then BA has the same eigenvalues as AB, counting multiplicity, together with an additional $n-m$ eigenvalues equal to 0; that is, $p_{BA}(x) = x^{n-m}p_{AB}(x)$.
50. [HJ91, p. 245] If $A \in F^{m\times m}$ and $B \in F^{n\times n}$, $\lambda \in \sigma(A)$, $\mu \in \sigma(B)$, with corresponding eigenvectors $\mathbf{u}$ and $\mathbf{v}$, respectively, then $\lambda\mu \in \sigma(A \otimes B)$, with corresponding eigenvector $\mathbf{u}\otimes\mathbf{v}$. (See Section 11.4 for the definition of $A \otimes B$.)

Examples:

1. Let $A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$. Then, viewing $A \in \mathbb{C}^{n\times n}$, $\sigma(A) = \{-i, i\}$. That is, A has no eigenvalues over the reals.
2. Let $A = \begin{bmatrix} -3 & 7 & -1 \\ 6 & 8 & -2 \\ 72 & -28 & 19 \end{bmatrix}$. Then $p_A(x) = (x+6)(x-15)^2 = q_A(x)$, $\lambda_1 = -6$, $\alpha(\lambda_1) = 1$, $\gamma(\lambda_1) = 1$, $\lambda_2 = 15$, $\alpha(\lambda_2) = 2$, $\gamma(\lambda_2) = 1$. Also, a set of linearly independent eigenvectors is $\left\{\begin{bmatrix} -1 \\ -2 \\ 4 \end{bmatrix}, \begin{bmatrix} -1 \\ 1 \\ 4 \end{bmatrix}\right\}$. So, A is not diagonalizable.
3. Let $A = \begin{bmatrix} 57 & -21 & 21 \\ -14 & 22 & -7 \\ -140 & 70 & -55 \end{bmatrix}$. Then $p_A(x) = (x+6)(x-15)^2$, $q_A(x) = (x+6)(x-15)$, $\lambda_1 = -6$, $\alpha(\lambda_1) = 1$, $\gamma(\lambda_1) = 1$, $\lambda_2 = 15$, $\alpha(\lambda_2) = 2$, $\gamma(\lambda_2) = 2$. Also, a set of linearly independent eigenvectors is $\left\{\begin{bmatrix} -1 \\ 0 \\ 2 \end{bmatrix}, \begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix}, \begin{bmatrix} -3 \\ 1 \\ 10 \end{bmatrix}\right\}$. So, A is diagonalizable.
4. Let $A = \begin{bmatrix} -5+4i & 1 & i \\ 2+8i & -4 & 2i \\ 20-4i & -4 & -i \end{bmatrix}$. Then $\sigma(A) = \{-6, -3, 3i\}$. If $B = \frac{1}{9}A^2 + 2A - 4I$, then $\sigma(B) = \{-12, -9, -5+6i\}$.
5. Let $A = \begin{bmatrix} -2 & 1 & 0 \\ 0 & -3i & 0 \\ 0 & 0 & 1 \end{bmatrix}$ and $B = \begin{bmatrix} -2 & 1 & 0 \\ 3 & -1 & 1 \\ 4 & 0 & 1 \end{bmatrix}$. B is nonsingular, so A and $B^{-1}AB = \begin{bmatrix} -1+3i & 1-i & i \\ 5+6i & -1-2i & 1+2i \\ 8-12i & -4+4i & 1-4i \end{bmatrix}$ have the same eigenvalues, which are given in the diagonal of A.
6. Let $A = \begin{bmatrix} 2 & -1 & 0 \\ 0 & 3 & 1 \end{bmatrix}$ and $B = \begin{bmatrix} 3 & 0 \\ 2 & 1 \\ 1 & 0 \end{bmatrix}$. Then $AB = \begin{bmatrix} 4 & -1 \\ 7 & 3 \end{bmatrix}$, $\sigma(AB) = \left\{\frac{1}{2}(7+3\sqrt{3}i), \frac{1}{2}(7-3\sqrt{3}i)\right\}$, $BA = \begin{bmatrix} 6 & -3 & 0 \\ 4 & 1 & 1 \\ 2 & -1 & 0 \end{bmatrix}$, and $\sigma(BA) = \left\{\frac{1}{2}(7+3\sqrt{3}i), \frac{1}{2}(7-3\sqrt{3}i), 0\right\}$.
7. Let $A = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & -3 & 2 \\ 0 & -1 & -2 & -4 \end{bmatrix}$. Then $p_A(x) = x^4 + 5x^3 + 4x^2 - 23x + 13$. $S_4(A), S_3(A)$, and $S_1(A)$ were computed in Example 4.2.1, and it is straightforward to verify that $S_2(A) = 4$.

Comparing these values to the characteristic polynomial, $S_4(A) = 13 = (-1)^4 13$, $S_3(A) = 23 = (-1)^3(-23)$, $S_2(A) = (-1)^2 4$, and $S_1(A) = (-1)(5)$. It follows that $S_4(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = \lambda_1\lambda_2\lambda_3\lambda_4 = 13$, $S_3(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = 23$, $S_2(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = 4$, and $S_1(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = \lambda_1 + \lambda_2 + \lambda_3 + \lambda_4 = -5$ (these values can also be verified with a computer algebra system or numerical software).

8. Let $p(x) = x^3 - 7x^2 - 3x + 2$, $C = C(p) = \begin{bmatrix} 0 & 0 & -2 \\ 1 & 0 & 3 \\ 0 & 1 & 7 \end{bmatrix}$. Then $p_C(x) = x^3 - 7x^2 - 3x + 2 = p(x)$. Also, $p_C(C) = -C^3 + 7C^2 + 3C - 2I = -\begin{bmatrix} -2 & -14 & -104 \\ 3 & 19 & 142 \\ 7 & 52 & 383 \end{bmatrix} + 7\begin{bmatrix} 0 & -2 & -14 \\ 0 & 3 & 19 \\ 1 & 7 & 52 \end{bmatrix}$ $+ 3\begin{bmatrix} 0 & 0 & -2 \\ 1 & 0 & 3 \\ 0 & 1 & 7 \end{bmatrix} - 2\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$.

9. Let $A = \begin{bmatrix} 3 & 0 & 0 \\ -2 & 4 & 1 \\ 1 & -6 & 9 \end{bmatrix} \in \mathbb{Q}^{3\times 3}$. Then $\sigma(A) = \{1, 6, 7\}$. The matrix $B = \begin{bmatrix} 3 & 0 & 0 \\ 1 & 3 & -\frac{10}{3} \\ -\frac{19}{3} & 20 & -\frac{41}{3} \end{bmatrix}$ $\in \mathbb{Q}^{3\times 3}$ commutes with A and $B = \frac{1}{3}A^2 + A + \frac{7}{3}I$.

10. Let $A = \begin{bmatrix} -3i & 0 & i & 0 \\ 0 & 3i & 0 & 0 \\ 0 & 0 & -2i & 0 \\ 0 & -\frac{i}{2} & 0 & 2i \end{bmatrix}$, is nonsingular ($\det A = 36$) and has $\lambda = 3i$ as an eigenvalue with multiplicity $\alpha(3i) = 1$, with corresponding eigenvector $\mathbf{x} = \begin{bmatrix} 0 \\ -2 \\ 0 \\ 1 \end{bmatrix}$, $\operatorname{adj} A = \begin{bmatrix} 12i & 0 & 6i & 0 \\ 0 & -12i & 0 & 0 \\ 0 & 0 & 18i & 0 \\ 0 & -3i & 0 & -18i \end{bmatrix}$ has $\lambda = -12i = 36\frac{1}{3i}$ as an eigenvalue with multiplicity $\alpha(-12i) = 1$, with corresponding eigenvector $\mathbf{x} = \begin{bmatrix} 0 \\ -2 \\ 0 \\ 1 \end{bmatrix}$.

11. [Gol07, p. 235] Let $A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 4 & -17 & 8 \end{bmatrix}$, then $\sigma(A) = \{2 - \sqrt{3}, 2 + \sqrt{3}, 4\}$. The columns of the matrix $\operatorname{adj}(A - 4I) = \begin{bmatrix} 1 & -4 & 1 \\ 4 & -16 & 4 \\ 16 & -64 & 16 \end{bmatrix}$ are eigenvectors of A corresponding to the eigenvalue $\lambda = 4$.

12. Let $A = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -3i \end{bmatrix}$ and $B = \begin{bmatrix} -2 & 7 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & i \end{bmatrix}$. Then $AB = BA = \begin{bmatrix} -2 & 5 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$. A and B share the eigenvector $\mathbf{x} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$, corresponding to the eigenvalues $\lambda = 1$ of A and $\mu = -2$ of B.

Applications:

1. (Markov Chains) (See also Chapter 72 for more information.) A Markov chain describes a process in which a system can be in any one of n states: $s_1, s_2, \ldots, s_n$. The probability of entering state s_i depends only on the state previously occupied by the system. The **transition probability** of entering state j, given that the system is in state i, is denoted by p_{ij}. The **transition matrix** is the matrix $P = [p_{ij}]$; its rows have sum 1. A (row or column) vector is a **probability vector** if its entries are nonnegative and sum to 1. The probabilty row vector $\pi^{(k)} = (\pi_1^{(k)}, \pi_2^{(k)}, \ldots \pi_n^{(k)})$, $k \geq 0$, is called the **state vector** of the system at time k if its ith entry is the probability that the system is in state s_i at time k. In particular, when $k = 0$, the state vector is called the **initial state vector** and its ith entry is the probability that the system begins at state s_i. It follows from probability theory that $\pi^{(k+1)} = \pi^{(k)} P$, and thus inductively that $\pi^{(k)} = \pi^{(0)} P^k$. If the entries of some power of P are all positive, then P is said to be **regular**. If P is a regular transition matrix, then as $n \to \infty$, $P^n \to \begin{bmatrix} \pi_1 & \pi_2 & \cdots & \pi_n \\ \pi_1 & \pi_2 & \cdots & \pi_n \\ \vdots & \vdots & \ddots & \vdots \\ \pi_1 & \pi_2 & \cdots & \pi_n \end{bmatrix}$. The row vector $\pi = (\pi_1, \pi_2, \ldots, \pi_n)$ is called the **steady state vector**, π is a probability vector, and as $n \to \infty$, $\pi^{(n)} \to \pi$. The vector π is the unique probability row vector with the property that $\pi P = \pi$. That is, π is the unique probability row vector that is a left eigenvector of P for eigenvalue 1.
2. (Differential Equations) [Mey00, pp. 541–546] Consider the system of linear differential equations $\begin{cases} x_1' &= a_{11}x_1 &+ a_{12}x_2 &+ \ldots &+ a_{1n}x_n \\ x_2' &= a_{21}x_1 &+ a_{22}x_2 &+ \ldots &+ a_{2n}x_n \\ \vdots & \vdots & \vdots & & \vdots \\ x_n' &= a_{n1}x_1 &+ a_{n2}x_2 &+ \ldots &+ a_{nn}x_n \end{cases}$, where each of the unknowns $x_1, x_2, \ldots, x_n$ is a differentiable function of the real variable t. This system of linear differential equations can be written in matrix form as $\mathbf{x}' = A\mathbf{x}$, where $A = [a_{ij}]$, $\mathbf{x} = \begin{bmatrix} x_1(t) \\ x_2(t) \\ \vdots \\ x_n(t) \end{bmatrix}$, and $\mathbf{x}' = \begin{bmatrix} x_1'(t) \\ x_2'(t) \\ \vdots \\ x_n'(t) \end{bmatrix}$. If A is diagonalizable, there exists a nonsingular matrix B (the columns of the matrix B are linearly independent eigenvectors of A), such that $B^{-1}AB = D$ is a diagonal matrix, so $\mathbf{x}' = BDB^{-1}\mathbf{x}$, or $B^{-1}\mathbf{x}' = DB^{-1}\mathbf{x}$. Let $\mathbf{u} = B^{-1}\mathbf{x}$. The linear system of differential equations $\mathbf{u}' = D\mathbf{u}$ has solution $\mathbf{u} = \begin{bmatrix} k_1 e^{\lambda_1 t} \\ k_2 e^{\lambda_2 t} \\ \vdots \\ k_n e^{\lambda_n t} \end{bmatrix}$, where $\lambda_1, \lambda_2, \ldots, \lambda_n$ are the eigenvalues of A. It follows that $\mathbf{x} = B\mathbf{u}$. (See also Chapter 78.)

3. (Dynamical Systems) [Lay12, pp. 278–279] Consider the dynamical system given by $\mathbf{u}_{k+1} = A\mathbf{u}_k$, where $A = [a_{ij}]$, $\mathbf{u}_0 = \begin{bmatrix} a_1 \\ a_2 \\ \vdots \\ a_n \end{bmatrix}$. If A is diagonalizable, there exist n linearly independent eigenvectors, $\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_n$, of A. The vector $\mathbf{u}_0$ can then be written as a linear combination of the eigenvectors, that is, $\mathbf{u}_0 = c_1\mathbf{x}_1 + c_2\mathbf{x}_2 + \cdots + c_n\mathbf{x}_n$. Then $\mathbf{u}_1 = A\mathbf{u}_0 = A\left(c_1\mathbf{x}_1 + c_2\mathbf{x}_2 + \cdots + c_n\mathbf{x}_n\right) = c_1\lambda_1\mathbf{x}_1 + c_2\lambda_2\mathbf{x}_2 + \cdots + c_n\lambda_n\mathbf{x}_n$. Inductively, $\mathbf{u}_{k+1} = A\mathbf{u}_k = c_1\lambda_1^{k+1}\mathbf{x}_1 + c_2\lambda_2^{k+1}\mathbf{x}_2 + \cdots + c_n\lambda_n^{k+1}\mathbf{x}_n$. Thus, the long-term behavior of the dynamical system can be studied using the eigenvalues of the matrix A. (See also Chapter 79.)

5.1 Inner Product Spaces

Definitions:

Let V be a vector space over the field F, where $F = \mathbb{R}$ or $F = \mathbb{C}$. An **inner product** on V is a function $\langle \cdot, \cdot \rangle$: $V \times V \to F$ such that for all $\mathbf{u}, \mathbf{v}, \mathbf{w} \in V$ and $a, b \in F$, the following hold:

- $\langle \mathbf{v}, \mathbf{v} \rangle \geq 0$ and $\langle \mathbf{v}, \mathbf{v} \rangle = 0$ if and only if $\mathbf{v} = \mathbf{0}$.
- $\langle a\mathbf{u} + b\mathbf{v}, \mathbf{w} \rangle = a\langle \mathbf{u}, \mathbf{w} \rangle + b\langle \mathbf{v}, \mathbf{w} \rangle$.
- For $F = \mathbb{R}$: $\langle \mathbf{u}, \mathbf{v} \rangle = \langle \mathbf{v}, \mathbf{u} \rangle$; For $F = \mathbb{C}$: $\langle \mathbf{u}, \mathbf{v} \rangle = \overline{\langle \mathbf{v}, \mathbf{u} \rangle}$ (where bar denotes complex conjugation).

A real (or complex) **inner product space** is a vector space V over $\mathbb{R}$ (or $\mathbb{C}$), together with an inner product defined on it.

In an inner product space V, the **norm**, or **length**, of a vector $\mathbf{v} \in V$ is $\|\mathbf{v}\| = \sqrt{\langle \mathbf{v}, \mathbf{v} \rangle}$.

An inner product space V is **complete** if for any sequence $\{\mathbf{x}_n\}$ in V such that $\|\mathbf{x}_n - \mathbf{x}_m\| \to 0$ as $n, m \to \infty$, there is $\mathbf{x} \in V$ such that $\|\mathbf{x}_n - \mathbf{x}\| \to 0$ as $n \to \infty$. A complete inner product space is also called a **Hilbert space**.

A vector $\mathbf{v} \in V$ is a **unit vector** if $\|\mathbf{v}\| = 1$.

The **angle** between two nonzero vectors $\mathbf{u}$ and $\mathbf{v}$ in a real inner product space is the real number θ, $0 \leq \theta \leq \pi$, such that $\langle \mathbf{u}, \mathbf{v} \rangle = \|\mathbf{u}\|\|\mathbf{v}\| \cos\theta$. See the Cauchy–Schwarz inequality (Fact 12).

Let V be an inner product space. The **distance** between two vectors $\mathbf{u}$ and $\mathbf{v}$ is $d(\mathbf{u}, \mathbf{v}) = \|\mathbf{u} - \mathbf{v}\|$.

A Hermitian matrix A is **positive definite** if $\mathbf{x}^*A\mathbf{x} > 0$ for all nonzero $\mathbf{x} \in \mathbb{C}^n$. (See Chapter 9 for more information on positive definite matrices.)

Facts:

All the following facts except those with a specific reference can be found in [Rom92, pp. 157–164, 267].

1. The vector space $\mathbb{R}^n$ under the **standard inner product**, or **dot product**
$$\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{u}^T\mathbf{v} = \sum_{i=1}^{n} u_i v_i$$
is an inner product space. It is often referred to as n–dimensional **Euclidean space**.
2. The vector space $\mathbb{C}^n$ under the **standard inner product**
$$\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{v}^*\mathbf{u} = \sum_{i=1}^{n} u_i \bar{v}_i$$
is an inner product space. It is often called n-dimensional **unitary space**.
3. [HJ85, p. 410] In $\mathbb{R}^n$, a function $\langle \cdot, \cdot \rangle \colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ is an inner product if and only if there exists a real symmetric positive definite matrix G such that $\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{u}^T G\mathbf{v}$, for all $\mathbf{u}, \mathbf{v} \in \mathbb{R}^n$.
4. [HJ85, p. 410] In $\mathbb{C}^n$, a function $\langle \cdot, \cdot \rangle \colon \mathbb{C}^n \times \mathbb{C}^n \to \mathbb{C}$ is an inner product if and only if there exists a Hermitian positive definite matrix H such that $\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{v}^* H\mathbf{u}$, for all $\mathbf{u}, \mathbf{v} \in \mathbb{C}^n$.
5. Let l^2 be the vector space of all infinite complex sequences $\mathbf{v} = (v_n)$ with the property that $\sum_{n=1}^{\infty} |v_n|^2 < \infty$. Then l^2 is an inner product space under the inner product
$$\langle \mathbf{u}, \mathbf{v} \rangle = \sum_{n=1}^{\infty} u_n \bar{v}_n.$$
l^2 is a Hilbert space.
6. Denote $L^2([a, b])$ the class of all measurable complex functions on $[a, b]$ such that the Lebesgue integral $\int_a^b |f(x)|^2 dx < \infty$. It is a complete inner product space under the inner product
$$\langle f, g \rangle = \int_a^b f(x)\overline{g(x)}dx.$$
7. If V is an inner product space and $\langle \mathbf{u}, \mathbf{w} \rangle = \langle \mathbf{v}, \mathbf{w} \rangle$ for all $\mathbf{w} \in V$, then $\mathbf{u} = \mathbf{v}$.
8. The inner product on an inner product space V, when restricted to vectors in a subspace S of V, is an inner product on S.
9. A finite dimensional inner product space is complete.
10. A complete subspace of an inner product space is closed.
11. A subspace of a Hilbert space is complete if and only if it is closed.
12. Let V be an inner product space. Then the norm function $\|\cdot\|$ on V has the following basic properties for all $\mathbf{u}, \mathbf{v} \in V$:
    (a) $\|\mathbf{v}\| \geq 0$ and $\|\mathbf{v}\| = 0$ if and only if $\mathbf{v} = \mathbf{0}$.
    (b) $\|a\mathbf{v}\| = |a|\|\mathbf{v}\|$, for all $a \in F$.

(c) (The Cauchy–Schwarz inequality) $|\langle \mathbf{u}, \mathbf{v}\rangle| \leq \|\mathbf{u}\|\|\mathbf{v}\|$ with equality if and only if $\{\mathbf{u}, \mathbf{v}\}$ is a linearly dependent set.

(d) $\|\mathbf{u}+\mathbf{v}\|^2 = \|\mathbf{u}\|^2 + 2\mathrm{Re}(\langle \mathbf{u}, \mathbf{v}\rangle) + \|\mathbf{v}\|^2$, where $\mathrm{Re}(z)$ denotes the real part of z.

(e) (The triangle inequality) $\|\mathbf{u}+\mathbf{v}\| \leq \|\mathbf{u}\| + \|\mathbf{v}\|$. When $\mathbf{u} \neq \mathbf{0}, \mathbf{v} \neq \mathbf{0}$, the equality holds if and only if $\mathbf{v} = a\mathbf{u}$, for some $a > 0$.

(f) $|\|\mathbf{u}\| - \|\mathbf{v}\|| \leq \|\mathbf{u}-\mathbf{v}\|$.

(g) (The parallelogram law) $\|\mathbf{u}+\mathbf{v}\|^2 + \|\mathbf{u}-\mathbf{v}\|^2 = 2\|\mathbf{u}\|^2 + 2\|\mathbf{v}\|^2$.

(h) (Polarization identities)

$$4\langle \mathbf{u}, \mathbf{v}\rangle = \begin{cases} \|\mathbf{u}+\mathbf{v}\|^2 - \|\mathbf{u}-\mathbf{v}\|^2, & \text{if } F = \mathbb{R}. \\ \|\mathbf{u}+\mathbf{v}\|^2 - \|\mathbf{u}-\mathbf{v}\|^2 + i\|\mathbf{u}+i\mathbf{v}\|^2 - i\|\mathbf{u}-i\mathbf{v}\|^2, & \text{if } F = \mathbb{C}. \end{cases}$$

13. The norm of a Hilbert space is strictly convex.

Examples:

1. Let $\mathbb{R}^4$ be the Euclidean space with the inner product $\langle \mathbf{u}, \mathbf{v}\rangle = \mathbf{u}^T\mathbf{v}$. Let $\mathbf{x} = [1, 2, 3, 4]^T \in \mathbb{R}^4$ and $\mathbf{y} = [3, -1, 0, 2]^T \in \mathbb{R}^4$ be two vectors. Then
   - $\langle \mathbf{x}, \mathbf{y}\rangle = 9$, $\|\mathbf{x}\| = \sqrt{30}$, and $\|\mathbf{y}\| = \sqrt{14}$.
   - The distance between $\mathbf{x}$ and $\mathbf{y}$ is $d(\mathbf{x}, \mathbf{y}) = \|\mathbf{x}-\mathbf{y}\| = \sqrt{26}$.
   - The angle between $\mathbf{x}$ and $\mathbf{y}$ is $\theta = \arccos \frac{9}{\sqrt{30}\sqrt{14}} = \arccos \frac{9}{2\sqrt{105}} \approx 1.116$ radians.
2. $\langle \mathbf{u}, \mathbf{v}\rangle = u_1v_1 + 2u_1v_2 + 2u_2v_1 + 6u_2v_2 = \mathbf{u}^T \begin{bmatrix} 1 & 2 \\ 2 & 6 \end{bmatrix} \mathbf{v}$ is an inner product on $\mathbb{R}^2$, as the matrix $G = \begin{bmatrix} 1 & 2 \\ 2 & 6 \end{bmatrix}$ is symmetric positive definite.
3. Let $C[-1, 1]$ be the class of all continuous real-valued functions on the closed interval $[-1, 1]$. Then it is an inner product space under the inner product $\langle f, g\rangle = \int_{-1}^{1} f(x)g(x)dx$. Let $f(x) = 1$ and $g(x) = x^2$ be two functions in $C[-1, 1]$. Then $\langle f, g\rangle = \int_{-1}^{1} x^2 dx = 2/3$, $\langle f, f\rangle = \int_{-1}^{1} 1dx = 2$, and $\langle g, g\rangle = \int_{-1}^{1} x^4 dx = 2/5$. The angle between f and g is $\arccos(\sqrt{5}/3)$ ≈ 0.730 radians.
4. [Mey00, p. 286] $\langle A, B\rangle = \mathrm{tr}(AB^*)$ is an inner product on $\mathbb{C}^{m\times n}$.

5.2 Orthogonality

Definitions:

Let V be an inner product space. Two vectors $\mathbf{u}, \mathbf{v} \in V$ are **orthogonal** if $\langle \mathbf{u}, \mathbf{v}\rangle = 0$, and this is denoted by $\mathbf{u} \perp \mathbf{v}$.

A subset S of an inner product space V is an **orthogonal set** if $\mathbf{u} \perp \mathbf{v}$, for all $\mathbf{u}, \mathbf{v} \in S$ such that $\mathbf{u} \neq \mathbf{v}$.

A subset S of an inner product space V is an **orthonormal set** if S is an orthogonal set and each $\mathbf{v} \in S$ is a unit vector.

Two subsets S_1 and S_2 of an inner product space V are **orthogonal** if $\mathbf{u} \perp \mathbf{v}$, for all $\mathbf{u} \in S_1$ and $\mathbf{v} \in S_2$, and this is denoted by $S_1 \perp S_2$.

The **orthogonal complement** of a subset S of an inner product space V is $S^{\perp} = \{\mathbf{w} \in V | \langle \mathbf{w}, \mathbf{v} \rangle = 0 \text{ for all } \mathbf{v} \in S\}$.

A **complete orthonormal set** M in an inner product space V is an orthonormal set of vectors in V such that for $\mathbf{v} \in V$, $\mathbf{v} \perp M$ implies that $\mathbf{v} = \mathbf{0}$.

An **orthogonal basis** for an inner product space V is an orthogonal set that is also a basis for V.

An **orthonormal basis** for V is an orthonormal set that is also a basis for V.

A matrix U is **unitary** if $U^*U = I$.

A real matrix Q is **orthogonal** if $Q^T Q = I$.

Facts:

1. [Mey00, p. 298] An orthogonal set of nonzero vectors is linearly independent. An orthonormal set of vectors is linearly independent.
2. [Rom92, p. 164] If S is a subset of an inner product space V, then $S^{\perp}$ is a subspace of V. Moreover, if S is a subspace of V, then $S \cap S^{\perp} = \{\mathbf{0}\}$.
3. [Mey00, p. 409] In an inner product space V, $\{\mathbf{0}\}^{\perp} = V$ and $V^{\perp} = \{\mathbf{0}\}$.
4. [Rom92, p. 168] If S is a finite dimensional subspace of an inner product space V, then for any $\mathbf{v} \in V$,
   (a) There are unique vectors $\mathbf{s} \in S$ and $\mathbf{t} \in S^{\perp}$ such that $\mathbf{v} = \mathbf{s} + \mathbf{t}$. This implies $V = S \oplus S^{\perp}$.
   (b) There is a unique linear operator P such that $P(\mathbf{v}) = \mathbf{s}$.
5. [Mey00, p. 404] If S is a subspace of an $n-$dimensional inner product space V, then
   (a) $(S^{\perp})^{\perp} = S$.
   (b) $\dim(S^{\perp}) = n - \dim(S)$.
6. [Rom92, p. 174] If S is a subspace of an infinite dimensional inner product space, then $S \subseteq (S^{\perp})^{\perp}$, but the two sets need not be equal.
7. [Rom92, p. 166] An orthonormal basis is a complete orthonormal set.
8. [Rom92, p. 166] In a finite-dimensional inner product space, a complete orthonormal set is a basis.
9. [Rom92, p. 165] In an infinite-dimensional inner product space, a complete orthonormal set may not be a basis.
10. [Rom92, p. 166] Every finite-dimensional inner product space has an orthonormal basis.
11. [Mey00, p. 299] Let $\mathcal{B} = \{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n\}$ be an orthonormal basis for V. Every vector $\mathbf{v} \in V$ can be uniquely expressed as

$$\mathbf{v} = \sum_{i=1}^{n} \langle \mathbf{v}, \mathbf{u}_i \rangle \mathbf{u}_i.$$

    The expression on the right is called the **Fourier expansion** of $\mathbf{v}$ with respect to $\mathcal{B}$ and the scalars $\langle \mathbf{v}, \mathbf{u}_i \rangle$ are called the **Fourier coefficients**.
12. [Mey00, p. 305] (Pythagorean Theorem) If $\{\mathbf{v}_i\}_{i=1}^{k}$ is an orthogonal set of vectors in V, then $\| \sum_{i=1}^{k} \mathbf{v}_i \|^2 = \sum_{i=1}^{k} \|\mathbf{v}_i\|^2$.
13. [Rom92, p. 167] (Bessel's Inequality) If $\{\mathbf{u}_i\}_{i=1}^{k}$ is an orthonormal set of vectors in V, then $\|\mathbf{v}\|^2 \geq \sum_{i=1}^{k} |\langle \mathbf{v}, \mathbf{u}_i \rangle|^2$.

14. [Mey00, p. 305] (Parseval's Identity) Let $\mathcal{B} = \{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n\}$ be an orthonormal basis for V. Then for each $\mathbf{v} \in V$, $\|\mathbf{v}\|^2 = \sum_{i=1}^{n} |\langle \mathbf{v}, \mathbf{u}_i \rangle|^2$.
15. [Mey00, p. 405] Let $A \in F^{m\times n}$, where $F = \mathbb{R}$ or $\mathbb{C}$. Then
    - (a) $\ker(A)^\perp = \text{range}(A^*)$, $\text{range}(A)^\perp = \ker(A^*)$.
    - (b) $F^m = \text{range}(A) \oplus \text{range}(A)^\perp = \text{range}(A) \oplus \ker(A^*)$.
    - (c) $F^n = \ker(A) \oplus \ker(A)^\perp = \ker(A) \oplus \text{range}(A^*)$.
16. [Mey00, p. 321] (See also Section 8.1.) The following statements for a real matrix $Q \in \mathbb{R}^{n\times n}$ are equivalent:
    - (a) Q is orthogonal.
    - (b) Q has orthonormal columns.
    - (c) Q has orthonormal rows.
    - (d) $QQ^T = I$, where I is the identity matrix of order n.
    - (e) For all $\mathbf{v} \in \mathbb{R}^n$, $\|Q\mathbf{v}\| = \|\mathbf{v}\|$.
17. [Mey00, p. 321] (See also Section 8.1.) The following statements for a complex matrix $U \in \mathbb{C}^{n\times n}$ are equivalent:
    - (a) U is unitary.
    - (b) U has orthonormal columns.
    - (c) U has orthonormal rows.
    - (d) $UU^* = I$, where I is the identity matrix of order n.
    - (e) For all $\mathbf{v} \in \mathbb{C}^n$, $\|U\mathbf{v}\| = \|\mathbf{v}\|$.

Examples:

1. Let $C[-1, 1]$ be the vector space with the inner product $\langle f, g\rangle = \int_{-1}^{1} f(x)g(x)dx$ and let $f(x) = 1$ and $g(x) = x$ be two functions in $C[-1, 1]$. Then $\langle f, g\rangle = \int_{-1}^{1} xdx = 0$. Thus, $f \perp g$.
2. The standard basis $\{\mathbf{e}_1, \mathbf{e}_2, \ldots, \mathbf{e}_n\}$ is an orthonormal basis of the unitary space $\mathbb{C}^n$.
3. The sequence of functions $\{e^{2\pi inx} : n = 0, \pm 1, \pm 2, \cdots\}$ forms an orthonormal basis of the inner product space $L^2([0, 1])$.
4. If $\{\mathbf{v}_1, \mathbf{v}_2, \cdots, \mathbf{v}_n\}$ is an orthogonal basis for $\mathbb{C}^n$ and $S = \text{span}\ \{\mathbf{v}_1, \mathbf{v}_2, \cdots, \mathbf{v}_k\}$ $(1 \leq k \leq n-1)$, then $S^\perp = \text{span}\ \{\mathbf{v}_{k+1}, \cdots, \mathbf{v}_n\}$.
5. The vectors $\mathbf{v}_1 = [2, 2, 1]^T$, $\mathbf{v}_2 = [1, -1, 0]^T$, and $\mathbf{v}_3 = [-1, -1, 4]^T$ are mutually orthogonal. They can be normalized to $\mathbf{u}_1 = \mathbf{v}_1/\|\mathbf{v}_1\| = [2/3, 2/3, 1/3]^T$, $\mathbf{u}_2 = \mathbf{v}_2/\|\mathbf{v}_2\| = [1/\sqrt{2}, -1/\sqrt{2}, 0]^T$, and $\mathbf{u}_3 = \mathbf{v}_3/\|\mathbf{v}_3\| = [-\sqrt{2}/6, -\sqrt{2}/6, 2\sqrt{2}/3]^T$. The set $\mathbb{B} = \{\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3\}$ forms an orthonormal basis for the Euclidean space $\mathbb{R}^3$.
    - If $\mathbf{v} = [v_1, v_2, v_3]^T \in \mathbb{R}^3$, then $\mathbf{v} = \langle \mathbf{v}, \mathbf{u}_1\rangle\mathbf{u}_1 + \langle \mathbf{v}, \mathbf{u}_2\rangle\mathbf{u}_2 + \langle \mathbf{v}, \mathbf{u}_3\rangle\mathbf{u}_3$, that is,

    $$\mathbf{v} = \frac{2v_1 + 2v_2 + v_3}{3}\mathbf{u}_1 + \frac{v_1 - v_2}{\sqrt{2}}\mathbf{u}_2 + \frac{-v_1 - v_2 + 4v_3}{3\sqrt{2}}\mathbf{u}_3.$$

    - The matrix $Q = [\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3] \in \mathbb{R}^{3\times 3}$ is an orthogonal matrix.
6. Let S be the subspace of $\mathbb{C}^3$ spanned by the vectors $\mathbf{u} = [i, 1, 1]^T$ and $\mathbf{v} = [1, i, 1]^T$. Then the orthogonal complement of S is

$$S^\perp = \{\mathbf{w} | \mathbf{w} = \alpha[1, 1, -1 + i]^T, \text{ where } \alpha \in \mathbb{C}\}.$$

7. Consider the inner product space l^2 from Fact 5.1.8. Let $\mathcal{E} = \{\mathbf{e}_i | i = 1, 2, \ldots\}$, where $\mathbf{e}_i$ has a 1 on ith place and 0s elsewhere. It is clear that $\mathcal{E}$ is an orthonormal set. If $\mathbf{v} = (v_n) \perp \mathcal{E}$, then for each n, $v_n = \langle \mathbf{v}, \mathbf{e}_n \rangle = 0$. This implies $\mathbf{v} = \mathbf{0}$. Therefore, $\mathcal{E}$ is a complete orthonormal set. However, $\mathcal{E}$ is not a basis for l^2 as $S = \text{span}\{\mathcal{E}\} \neq l^2$. Further, $S^\perp = \{\mathbf{0}\}$. Thus, $(S^\perp)^\perp = l^2 \not\subseteq S$ and $l^2 \neq S \oplus S^\perp$.
8. Matrix
$$\begin{bmatrix} 0.6 & 0.8i \\ 0.8i & 0.6 \end{bmatrix}$$
is unitary.

5.3 Adjoints of Linear Operators on Inner Product Spaces

Definitions:

Let V and W be complete inner product spaces. Let $T \in L(V, W)$.

A linear transformation $T^* \in L(W, V)$ is called an **adjoint** of T if $\langle T(\mathbf{x}), \mathbf{y} \rangle = \langle \mathbf{x}, T^*(\mathbf{y}) \rangle$ for all $\mathbf{x} \in V, \mathbf{y} \in W$.

A linear operator $T \in L(V, V)$ is called **self-adjoint**, or **Hermitian**, if $T = T^*$.

A linear operator $T \in L(V, V)$ is called **unitary** if $T^*T = I_V$.

A linear operator $T \in L(V, V)$ is called **normal** if $TT^* = T^*T$.

A self-adjoint operator T is called **positive semidefinite** if $\langle T(\mathbf{x}), \mathbf{x} \rangle \geq 0$ for all $\mathbf{x} \in V$ and **positive definite** if $\langle T(\mathbf{x}), \mathbf{x} \rangle > 0$ for all non-zero $\mathbf{x} \in V$.

A linear operator $T \in L(V, V)$ is an **isometry** if it preserves norms, i.e., $\|T(\mathbf{x})\| = \|\mathbf{x}\|$ for all $\mathbf{x} \in V$.

Let U be a vector space over a field F and T a linear operator on U. A scalar $\lambda \in F$ is called an **eigenvalue** of T if there exists a non-zero $\mathbf{x} \in U$ such that $T(\mathbf{x}) = \lambda\mathbf{x}$, and each such non-zero $\mathbf{x}$ is called an **eigenvector** of T corresponding to eigenvalue λ.

Let V be a finite dimensional inner product space and let T be a linear operator on V. T is **orthogonally diagonalizable** if V has an orthonormal basis $\mathcal{B}$ such that $[T]_\mathcal{B}$ is a diagonal matrix, or equivalently, V has an orthonormal basis consisting of eigenvectors of T.

Facts:

The following facts can be found in [Coo10], [HK71], or [Rom92] . Unless otherwise specified, U, V, and W denote finite dimensional (real or complex) inner product spaces.

1. Let f be a linear functional on V. Then there exists a unique $\mathbf{v} \in V$ such that $f(\mathbf{x}) = \langle \mathbf{x}, \mathbf{v} \rangle$ for all $\mathbf{x} \in V$.
2. The adjoint T^* of $T \in L(V, W)$ exists and is unique.
3. Let $\mathcal{B}_V$ be an ordered orthonormal basis for V and $\mathcal{B}_W$ be an ordered orthonormal basis for W. Let A be the matrix of $T \in L(V, W)$ with respect to $\mathcal{B}_V$ and $\mathcal{B}_W$ and B be the matrix of $T^* \in L(W, V)$ with respect to $\mathcal{B}_W$ and $\mathcal{B}_V$. Then $B = A^*$.
4. (Properties of adjoint operators)
   (a) If $T \in L(U, V)$, $(T^*)^* = T$.
   (b) If $T \in L(U, V)$ and $\alpha \in F$, $(\alpha T)^* = \bar{\alpha} T^*$.
   (c) If $T, S \in L(U, V)$, $(T + S)^* = T^* + S^*$.
   (d) If $T \in L(U, V), S \in L(V, W)$, $(TS)^* = S^*T^*$.
   (e) If $T \in L(V, V)$ is invertible, then $(T^*)^{-1} = (T^{-1})^*$.
5. Let $T \in L(V, W)$. Then
   (a) $\text{range}(T^*) = \ker(T)^\perp$; $\ker(T^*) = \text{range}(T)^\perp$.

   (b) $\operatorname{range}(T^*T) = \operatorname{range}(T^*)$; $\ker(T^*T) = \ker(T)$.
   (c) $V = \ker(T) \oplus \operatorname{range}(T^*)$; $W = \ker(T^*) \oplus \operatorname{range}(T)$.

6. Let $\mathcal{B}$ be an ordered orthonormal basis of V and $T \in L(V, V)$. Let $A = [T]_{\mathcal{B}}$. Then
   (a) T is self-adjoint if and only if A is a Hermitian matrix.
   (b) T is unitary if and only if A is a unitary matrix.
   (c) T is normal if and only if A is a normal matrix.
   (d) T is positive definite (semidefinite) if and only if A is positive definite (semidefinite).
7. If T and S are unitary operators on V, then
   (a) $TT^* = I_V$.
   (b) T^{-1} exists and $T^{-1} = T^*$.
   (c) T^* is unitary.
   (d) TS is unitary.
8. The following are equivalent:
   (a) T is a unitary operator on V.
   (b) $\langle T(\mathbf{x}), T(\mathbf{y})\rangle = \langle \mathbf{x}, \mathbf{y}\rangle$ for all $\mathbf{x}, \mathbf{y} \in V$.
   (c) T maps an orthonormal basis of V to an orthonormal basis of V.
   (d) There exists an orthonormal basis $(\mathbf{v}_1, \mathbf{v}_2, \cdots, \mathbf{v}_n)$ such that $(T(\mathbf{v}_1), T(\mathbf{v}_2), \cdots, T(\mathbf{v}_n))$ is an orthonormal basis.
9. An operator on a finite dimentional inner product space is an isometry if and only if it is a unitary operator.
10. An isometry on an infinite dimensional Hilbert space is not necessarily unitary.
11. Let $T \in L(V, V)$ be a unitary operator. If λ is an eigenvalue of T, then $|\lambda| = 1$.
12. Self-adjoint operators and unitary operators are normal operators.
13. Let T and S be self-adjoint operators on V.
   (a) If T is invertible, then T^{-1} is self-adjoint.
   (b) $S + T$ is self-adjoint.
   (c) ST is self-adjoint if and only if $ST = TS$.
14. Let T be a self-adjoint operator on V.
   (a) $\langle T(\mathbf{x}), \mathbf{x}\rangle \in \mathbb{R}$ for any $\mathbf{x} \in V$.
   (b) $\langle T(\mathbf{x}), \mathbf{x}\rangle = 0$ for all $\mathbf{x} \in V$ implies that $T \equiv 0$.
   (c) T has an eigenvector.
   (d) All eigenvalues of T are real.
   (e) Eigenvectors of T corresponding to distinct eigenvalues are orthogonal.
15. Let V be a finite dimensional real inner product space and T a linear operator on V. Then T is orthogonally diagonalizable if and only if T is self-adjoint.
16. For any real symmetric matrix, there exists an orthogonal matrix P such that $P^T AP$ is diagonal.
17. Let T be a linear operator on V. Then T is normal if and only if $\|T(\mathbf{x})\| = \|T^*(\mathbf{x})\|$ for all $\mathbf{x} \in V$.
18. Let T be a normal operator on V.
   (a) If for $\mathbf{x} \in V$ and $\lambda \in F$, $T(\mathbf{x}) = \lambda\mathbf{x}$, then $T^*(\mathbf{x}) = \bar{\lambda}\mathbf{x}$.
   (b) If $T(\mathbf{x}) = \mathbf{0}$, then $T^*(\mathbf{x}) = \mathbf{0}$.

   (c) If $T^k(\mathbf{x}) = \mathbf{0}$ for some $k \geq 1$, then $T(\mathbf{x}) = \mathbf{0}$.
   (d) For any polynomial $p(t)$ on F, the operator $p(T) \in L(V, V)$ is normal.
   (e) Eigenvectors of T corresponding to distinct eigenvalues are orthogonal.

19. Let V be a finite dimensional complex inner product space and T is a linear operator on V. Then V has an orthonormal basis in which the matrix of T is upper triangular.
20. For any matrix $A \in \mathbb{C}^{n\times n}$, there is a unitary matrix Q such that Q^*AQ is upper-triangular.
21. Let V be a finite dimensional complex inner product space and T a linear operator on V. Then T is orthogonally diagonalizable if and only if T is normal.
22. Let $A \in \mathbb{C}^{n\times n}$. Then A is a normal matrix if and only if there exists a unitary matrix Q such that Q^*AQ is a diagonal matrix.
23. Let V be a finite dimensional real inner product space and T a linear operator on V. Then T is normal but not self-adjoint if and only if there is an ordered orthonormal basis $\mathcal{B}$ such that $[T]_{\mathcal{B}}$ is a block diagonal matrix $\operatorname{diag}(A_1, A_2, \cdots, A_k)$, where each diagonal block A_i is a real 1×1 matrix or a real 2×2 matrix of the form $\begin{bmatrix} \mu_i & -\nu_i \\ \nu_i & \mu_i \end{bmatrix}$ for some $\nu_i > 0$; and at least one block is 2×2.
24. Let $T \in L(V, V)$. Then each of the following statements is equivalent to "T is a positive semidefinite operator":
   (a) T is self-adjoint and each eigenvalue of T is nonnegative.
   (b) There exists an operator R on V such that $R^*R = T$.
   (c) There exists a positive semidefinite operator S on V such that $S^2 = T$.
   (d) There exists a self-adjoint operator S on V such that $S^2 = T$.
25. Let $T \in L(V, V)$. Then each of the following statements is equivalent to "T is a positive definite operator":
   (a) T is self-adjoint and each eigenvalue of T is positive.
   (b) There exists an invertible operator R on V such that $R^*R = T$.
   (c) There exists a positive definite operator S on V such that $S^2 = T$.
   (d) There exists an invertible self-adjoint operator S on V such that $S^2 = T$.
26. Let T be a positive semidefinite (definite) operator. Then there is a unique positive semidefinite (definite) operator S such that $S^2 = T$. This S is called the **square root** of T and denoted by $\sqrt{T}$.
27. (*Polar Decomposition*) Let $T \in L(V, V)$. Then there exists a unitary operator P such that $T = P\sqrt{T^*T}$.

Examples:

1. Consider the space $\mathbb{R}^3$ equipped with the standard inner product and let $f(\mathbf{w}) = 3w_1 - 2w_3$. Then with $\mathbf{v} = [3, 0, -2]^T$, $f(\mathbf{w}) = \langle \mathbf{w}, \mathbf{v}\rangle$.
2. Consider the space $\mathbb{R}^3$ equipped with the standard inner product. Let $\mathbf{v} = \begin{bmatrix} x \\ y \\ z \end{bmatrix}$ and $T(\mathbf{v}) = \begin{bmatrix} 2x + y \\ y - 3z \\ x + y + z \end{bmatrix}$. Then $[T] = \begin{bmatrix} 2 & 1 & 0 \\ 0 & 1 & -3 \\ 1 & 1 & 1 \end{bmatrix}$, so $[T]^* = \begin{bmatrix} 2 & 0 & 1 \\ 1 & 1 & 1 \\ 0 & -3 & 1 \end{bmatrix}$, and $T^*(\mathbf{v}) = \begin{bmatrix} 2x + z \\ x + y + z \\ -3y + z \end{bmatrix}$.
3. Consider the space $\mathbb{C}^{n\times n}$ equipped with the inner product in Example 5.1.4. Let $A, B \in \mathbb{C}^{n\times n}$ and let T be the linear operator on $\mathbb{C}^{n\times n}$ defined by $T(X) = AX + XB,\ X \in \mathbb{C}^{n\times n}$. Then $T^*(X) = A^*X + XB^*,\ X \in \mathbb{C}^{n\times n}$.

4. Let V be an inner product space and let T be a linear operator on V. For a fixed $\mathbf{u} \in V$, $f(\mathbf{x}) = \langle T(\mathbf{x}), \mathbf{u} \rangle$ is a linear functional. By Fact 1, there is a unique vector $\mathbf{v}$ such that $f(\mathbf{x}) = \langle \mathbf{x}, \mathbf{v} \rangle$. Then $T^*(\mathbf{u}) = \mathbf{v}$.
5. Consider $V = \mathbb{R}^3$ and $\mathcal{B} = \{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$. Then the linear operator T with

$$[T]_{\mathcal{B}} = \frac{1}{3} \begin{bmatrix} 3 & -2 & 2 \\ 2 & 3 & -1 \\ -2 & 2 & 3 \end{bmatrix}$$

is normal but not self-adjoint. There is an orthonormal basis $\mathcal{U} = \{\mathbf{u}_1 = [1/3, 2/3, 2/3]^T, \mathbf{u}_2 = [2/3, -2/3, 1/3]^T, \mathbf{u}_3 = [2/3, 1/3, -2/3]^T\}$ such that

$$[T]_{\mathcal{U}} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & -1 \\ 0 & 1 & 1 \end{bmatrix}.$$

T is not orthogonally diagonalizable in $V = \mathbb{R}^3$. However, it is orthogonally diagonalizable in $\mathbb{C}^3$ since it is normal.
6. Consider the infinite dimensional Hilbert space l^2. Let $T \in L(l^2, l^2)$ be the linear operator: $T(\xi_1, \xi_2, \cdots) = (0, \xi_1, \xi_2, \cdots)$. Then T is an isometry on l^2. However, T is not unitary.

5.4 Orthogonal Projection

Definitions:

Let S be a finite-dimensional subspace of an inner product space V. Then according to Fact 5.2.4, each $\mathbf{v} \in V$ can be written uniquely as $\mathbf{v} = \mathbf{s} + \mathbf{t}$, where $\mathbf{s} \in S$ and $\mathbf{t} \in S^{\perp}$.

The vector $\mathbf{s}$ is called the **orthogonal projection** of $\mathbf{v}$ onto S and is often written as $\mathrm{Proj}_S \mathbf{v}$, where the linear operator Proj_S is called the **orthogonal projection** onto S along $S^{\perp}$. When $V = \mathbb{C}^n$ or $V = \mathbb{R}^n$ with the standard inner product, the linear operator Proj_S is often identified with its standard matrix $[\mathrm{Proj}_S]$ and Proj_S is used to denote both the operator and the matrix.

Let $P_1, P_2 \in L(V, V)$. If $P_1 P_2 = P_2 P_1 = 0 \in L(V, V)$, then P_1 and P_2 are said to be orthogonal to each other, and this is denoted by $P_1 \perp P_2$.

Facts:

All the following facts except those with a specific reference can be found in [Mey00, pp. 430–435] or [Rom92, pp. 191–192].

1. An orthogonal projection is a projection (as defined in Section 3.6).
2. Suppose that P is a projection. The following statements are equivalent:
   (a) P is an orthogonal projection.
   (b) $P^* = P$.
   (c) $\mathrm{range}(P) \perp \ker(P)$.
3. Let $P \in L(V, V)$. Then P is an orthogonal projection if and only if $P^2 = P$ and $\|P(\mathbf{x})\| \leq \|\mathbf{x}\|$ for all $\mathbf{x} \in V$.
4. Let $P_1, P_2 \in L(V, V)$ be orthogonal projections. Then $P_1 \perp P_2$ if and only if $\mathrm{range}(P_1) \perp \mathrm{range}(P_2)$.
5. Let $P_1, P_2 \in L(V, V)$ be orthogonal projections. Then
   (a) $P = P_1 + P_2$ is an orthogonal projection if and only if $P_1 \perp P_2$.

   (b) If $P_1 \perp P_2$, then $P = P_1 + P_2$ is an orthogonal projection onto range$(P_1) \oplus$ range(P_2).

6. Let $P_1, P_2 \in L(V, V)$ be orthogonal projections. Then
   (a) $P = P_1P_2$ is an orthogonal projection if and only if $P_1P_2 = P_2P_1$.
   (b) If $P_1P_2 = P_2P_1$, then $P = P_1P_2$ is an orthogonal projection onto range$(P_1) \cap$ range(P_2).
7. Let $P_1, P_2 \in L(V, V)$ be orthogonal projections. Then
   (a) $P = P_1 - P_2$ is an orthogonal projection if and only if $P_1P_2 = P_2P_1 = P_2$.
   (b) When $P = P_1 - P_2$ is an orthogonal projection, P is an orthogonal projection onto range$(P_1) \oplus$ range$(P_2)^{\perp}$.
8. If S is a subspace of a finite dimensional inner product space V, then

$$\text{Proj}_{S^{\perp}} = I - \text{Proj}_S.$$

9. Let S be a p–dimensional subspace of the standard inner product space $\mathbb{C}^n$, and let the columns of matrices $M \in \mathbb{C}^{n\times p}$ and $N \in \mathbb{C}^{n\times(n-p)}$ be bases for S and $S^{\perp}$, respectively. Then the orthogonal projections onto S and $S^{\perp}$ are

$$\text{Proj}_S = M(M^*M)^{-1}M^* \quad \text{and} \quad \text{Proj}_{S^{\perp}} = N(N^*N)^{-1}N^*.$$

   If M and N contain orthonormal bases for S and $S^{\perp}$, then $\text{Proj}_S = MM^*$ and $\text{Proj}_{S^{\perp}} = NN^*$.
10. [Lay03, p. 399] If $\{\mathbf{u}_1, \ldots, \mathbf{u}_p\}$ is an orthonormal basis for a subspace S of $\mathbb{C}^n$, then for any $\mathbf{v} \in \mathbb{C}^n$,

$$\text{Proj}_S\mathbf{v} = (\mathbf{u}_1^*\mathbf{v})\mathbf{u}_1 + \cdots + (\mathbf{u}_p^*\mathbf{v})\mathbf{u}_p.$$

11. [TB97, p. 46] Let $\mathbf{v} \in \mathbb{C}^n$ be a nonzero vector. Then
   (a) $\text{Proj}_{\mathbf{v}} = \dfrac{\mathbf{v}\mathbf{v}^*}{\mathbf{v}^*\mathbf{v}}$ is the orthogonal projection onto the line $L = \text{span}\{\mathbf{v}\}$.
   (b) $\text{Proj}_{\perp\mathbf{v}} = I - \dfrac{\mathbf{v}\mathbf{v}^*}{\mathbf{v}^*\mathbf{v}}$ is the orthogonal projection onto $L^{\perp}$.
12. (The Best Approximation Theorem) Let S be a finite dimensional subspace of an inner product space V and let $\mathbf{b}$ be a vector in V. Then $\text{Proj}_S\mathbf{b}$ is the unique vector in S that is closest to $\mathbf{b}$ in the sense that

$$\min_{\mathbf{s}\in S} \|\mathbf{b} - \mathbf{s}\| = \|\mathbf{b} - \text{Proj}_S\mathbf{b}\|.$$

   The vector $\text{Proj}_S\mathbf{b}$ is called *the best approximation to* $\mathbf{b}$ *by the elements of* S.

Examples:

1. Generally, an orthogonal projection $P \in \mathbb{C}^{n\times n}$ is not a unitary matrix.
2. Let $\{\mathbf{v}_1, \mathbf{v}_2, \cdots, \mathbf{v}_n\}$ be an orthogonal basis for $\mathbb{R}^n$ and let S the subspace of $\mathbb{R}^n$ spanned by $\{\mathbf{v}_1, \cdots, \mathbf{v}_k\}$, where $1 \leq k \leq n-1$. Then $\mathbf{w} = c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \cdots + c_n\mathbf{v}_n \in \mathbb{R}^n$ can be written as $\mathbf{w} = \mathbf{s} + \mathbf{t}$, where $\mathbf{s} = c_1\mathbf{v}_1 + \cdots + c_k\mathbf{v}_k \in S$ and $\mathbf{t} = c_{k+1}\mathbf{v}_{k+1} + \cdots + c_n\mathbf{v}_n \in S^{\perp}$.
3. Let $\mathbf{u}_1 = [2/3, 2/3, 1/3]^T$, $\mathbf{u}_2 = [1/3, -2/3, 2/3]^T$, and $\mathbf{x} = [2, 3, 5]^T$. Then $\{\mathbf{u}_1, \mathbf{u}_2\}$ is an orthonormal basis for the subspace $S = \text{span}\ \{\mathbf{u}_1, \mathbf{u}_2\}$ of $\mathbb{R}^3$.
   - The orthogonal projection of $\mathbf{x}$ onto S is

$$\text{Proj}_S\mathbf{x} = \left(\mathbf{u}_1^T\right)\mathbf{x}\mathbf{u}_1 + \left(\mathbf{u}_2^T\mathbf{x}\right)\mathbf{u}_2 = [4, 2, 3]^T.$$

- The orthogonal projection of $\mathbf{x}$ onto $S^\perp$ is $\mathbf{y} = \mathbf{x} - \text{Proj}_S\mathbf{x} = [-2, 1, 2]^T$.
- The vector in S that is closest to $\mathbf{x}$ is $\text{Proj}_S\mathbf{x} = [4, 2, 3]^T$.
- Let $M = [\mathbf{u}_1, \mathbf{u}_2]$. Then the orthogonal projection onto S is

$$\text{Proj}_S = MM^T = \frac{1}{9}\begin{bmatrix} 5 & 2 & 4 \\ 2 & 8 & -2 \\ 4 & -2 & 5 \end{bmatrix}.$$

- The orthogonal projection of any $\mathbf{v} \in \mathbb{R}^3$ onto S can be computed by $\text{Proj}_S\mathbf{v} = MM^T\mathbf{v}$. In particular, $MM^T\mathbf{x} = [4, 2, 3]^T$.

4. Let $\mathbf{w}_1 = [1, 1, 0]^T$ and $\mathbf{w}_2 = [1, 0, 1]^T$. Consider the subspace $W = \text{span}\{\mathbf{w}_1, \mathbf{w}_2\}$ of $\mathbb{R}^3$. Define the matrix $M = [\mathbf{w}_1, \mathbf{w}_2] = \begin{bmatrix} 1 & 1 \\ 1 & 0 \\ 0 & 1 \end{bmatrix}$. Then $M^TM = \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}$.

- The orthogonal projection onto W is $\text{Proj}_W = M(M^TM)^{-1}M^T =$

$$\begin{bmatrix} 1 & 1 \\ 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}^{-1} \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} = \frac{1}{3}\begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix}.$$

- The orthogonal projection of any $\mathbf{v} \in \mathbb{R}^3$ onto W can be computed by $\text{Proj}_W\mathbf{v}$. For $\mathbf{v} = [1, 2, 3]^T$, $\text{Proj}_W\mathbf{v} = \text{Proj}_W[1, 2, 3]^T = [7/3, 2/3, 5/3]^T$.

5.5 Gram–Schmidt Orthogonalization and QR Factorization

Definitions:

Let $\{\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_n\}$ be a basis for a subspace S of an inner product space V. An orthonormal basis $\{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n\}$ for S can be constructed using the following Gram–Schmidt orthogonalization process:

$$\mathbf{u}_1 = \frac{\mathbf{a}_1}{\|\mathbf{a}_1\|} \quad \text{and} \quad \mathbf{u}_k = \frac{\mathbf{a}_k - \sum_{i=1}^{k-1}\langle \mathbf{a}_k, \mathbf{u}_i\rangle \mathbf{u}_i}{\|\mathbf{a}_k - \sum_{i=1}^{k-1}\langle \mathbf{a}_k, \mathbf{u}_i\rangle \mathbf{u}_i\|}, \quad \text{for} \quad k = 2, \ldots, n.$$

A **reduced QR factorization** of $A \in \mathbb{C}^{m\times n}$ $(m \geq n)$ is a factorization $A = \hat{Q}\hat{R}$, where $\hat{Q} \in \mathbb{C}^{m\times n}$ has orthonormal columns and $\hat{R} \in \mathbb{C}^{n\times n}$ is an upper triangular matrix.

A **QR factorization** of $A \in \mathbb{C}^{m\times n}$ $(m \geq n)$ is a factorization $A = QR$, where $Q \in \mathbb{C}^{m\times m}$ is a unitary matrix and $R \in \mathbb{C}^{m\times n}$ is an upper triangular matrix with the last $m - n$ rows of R being zero.

Facts:

1. [TB97, p. 51] Each $A \in \mathbb{C}^{m\times n}$ $(m \geq n)$ has a full QR factorization $A = QR$. If $A \in \mathbb{R}^{m\times n}$, then both Q and R may be taken to be real.
2. [TB97, p. 52] Each $A \in \mathbb{C}^{m\times n}$ $(m \geq n)$ has a reduced QR factorization $A = \hat{Q}\hat{R}$. If $A \in \mathbb{R}^{m\times n}$, then both $\hat{Q}$ and $\hat{R}$ may be taken to be real.
3. [TB97, p. 52] Each $A \in \mathbb{C}^{m\times n}$ $(m \geq n)$ of full rank has a unique reduced QR factorization $A = \hat{Q}\hat{R}$, where $\hat{Q} \in \mathbb{C}^{m\times n}$ and $\hat{R} \in \mathbb{C}^{n\times n}$ with real $r_{ii} > 0$.
4. [TB97, p. 48] The orthonormal basis $\{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n\}$ generated via the Gram–Schmidt orthogonalization process has the property

$$\text{Span}(\{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_k\}) = \text{Span}(\{\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_k\}),$$

for $k = 1, 2, \ldots, n$.

5. [TB97, p. 51]

```
Algorithm 1: Classical Gram–Schmidt Orthogonalization:
input: a basis $\{\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_n\}$ for a subspace $S$
output: an orthonormal basis $\{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n\}$ for $S$
for $j = 1 : n$
    $\mathbf{u}_j := \mathbf{a}_j$
    for $i = 1 : j - 1$
        $r_{ij} := \langle \mathbf{a}_j, \mathbf{u}_i \rangle$
        $\mathbf{u}_j := \mathbf{u}_j - r_{ij}\mathbf{u}_i$
    end
    $r_{jj} := \|\mathbf{u}_j\|$
    $\mathbf{u}_j := \mathbf{u}_j / r_{jj}$
end
```

6. [TB97, p. 58]

```
Algorithm 2: Modified Gram–Schmidt Orthogonalization
input: a basis $\{\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_n\}$ for a subspace $S$
output: an orthonormal basis $\{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n\}$ for $S$
$\mathbf{w}_i := \mathbf{a}_i$, $i = 1 : n$
for $i = 1 : n$
    $r_{ii} := \|\mathbf{w}_i\|$
    $\mathbf{u}_i := \mathbf{w}_i / r_{ii}$
    for $j = i + 1 : n$
        $r_{ij} := \langle \mathbf{w}_j, \mathbf{u}_i \rangle$
        $\mathbf{w}_j := \mathbf{w}_j - r_{ij}\mathbf{u}_i$
    end
end
```

7. [Mey00, p. 315] If exact arithmetic is used, then Algorithms 1 and 2 generate the same orthonormal basis $\{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n\}$ and the same r_{ij}, for $j \geq i$.
8. [GV96, pp. 230–232] If $A = [\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_n] \in \mathbb{C}^{m \times n}$ $(m \geq n)$ is of full rank n, then the classic or modified Gram–Schmidt process leads to a reduced QR factorization $A = \hat{Q}\hat{R}$, with $\hat{Q} = [\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n]$ and $\hat{R}_{ij} = r_{ij}$, for $j \geq i$, and $\hat{R}_{ij} = 0$, for $j < i$.
9. [GV96, p. 232] The costs of Algorithm 1 and Algorithm 2 are both $2mn^2$ flops when applied to compute a reduced QR factorization of a matrix $A \in \mathbb{R}^{m \times n}$.
10. [Mey00, pp. 317, 349] For the QR factorization, Algorithm 1 and Algorithm 2 are not numerically stable. However, Algorithm 2 often yields better numerical results than Algorithm 1.
11. [Mey00, p. 349] Algorithm 2 is numerically stable when it is used to solve least squares problems.
12. (Numerically stable algorithms for computing the QR factorization using Householder reflections and Givens rotations are given in Chapter 51.)
13. [TB97, p. 54] (See also Chapter 51.) If $A = QR$ is a QR factorization of the rank n matrix $A \in \mathbb{C}^{n \times n}$, then the linear system $A\mathbf{x} = \mathbf{b}$ can be solved as follows:
    (a) Compute the factorization $A = QR$.
    (b) Compute the vector $\mathbf{c} = Q^*\mathbf{b}$.
    (c) Solve $R\mathbf{x} = \mathbf{c}$ by performing back substitution.

Examples:

1. Consider the matrix $A = \begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix}$.

   - A has a (full) QR factorization $A = QR$:

$$\begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix} = \begin{bmatrix} \frac{1}{\sqrt{5}} & \frac{4}{3\sqrt{5}} & -\frac{2}{3} \\ \frac{2}{\sqrt{5}} & -\frac{2}{3\sqrt{5}} & \frac{1}{3} \\ 0 & \frac{\sqrt{5}}{3} & \frac{2}{3} \end{bmatrix} \begin{bmatrix} \sqrt{5} & \frac{2}{\sqrt{5}} \\ 0 & \frac{6}{\sqrt{5}} \\ 0 & 0 \end{bmatrix}.$$

   - A has a reduced QR factorization $A = \hat{Q}\hat{R}$:

$$\begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix} = \begin{bmatrix} \frac{1}{\sqrt{5}} & \frac{4}{3\sqrt{5}} \\ \frac{2}{\sqrt{5}} & -\frac{2}{3\sqrt{5}} \\ 0 & \frac{\sqrt{5}}{3} \end{bmatrix} \begin{bmatrix} \sqrt{5} & \frac{2}{\sqrt{5}} \\ 0 & \frac{6}{\sqrt{5}} \end{bmatrix}.$$

2. Consider the matrix $A = \begin{bmatrix} 3 & 1 & -2 \\ 3 & -4 & 1 \\ 3 & -4 & -1 \\ 3 & 1 & 0 \end{bmatrix}$. Using the classic or modified Gram–Schmidt process gives the following reduced QR factorization:

$$\begin{bmatrix} 3 & 1 & -2 \\ 3 & -4 & 1 \\ 3 & -4 & -1 \\ 3 & 1 & 0 \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & \frac{1}{2} & -\frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} 6 & -3 & -1 \\ 0 & 5 & -1 \\ 0 & 0 & 2 \end{bmatrix}.$$

5.6 Singular Value Decomposition

Definitions:

A **singular value decomposition (SVD)** of a matrix $A \in \mathbb{C}^{m\times n}$ is a factorization

$$A = U\Sigma V^*, \quad \Sigma = \mathrm{diag}(\sigma_1, \sigma_2, \ldots, \sigma_p) \in \mathbb{R}^{m\times n}, \ p = \min\{m, n\},$$

where $\sigma_1 \geq \sigma_2 \geq \ldots \geq \sigma_p \geq 0$ and both $U = [\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_m] \in \mathbb{C}^{m\times m}$ and $V = [\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n] \in \mathbb{C}^{n\times n}$ are unitary. The diagonal entries of Σ are called the **singular values** of A. The columns of U are called **left singular vectors** of A and the columns of V are called **right singular vectors** of A.

Let $A \in \mathbb{C}^{m\times n}$ with rank $r \leq p = \min\{m, n\}$. A **reduced singular value decomposition (reduced SVD)** of A is a factorization

$$A = \hat{U}\hat{\Sigma}\hat{V}^*, \quad \hat{\Sigma} = \mathrm{diag}(\sigma_1, \sigma_2, \ldots, \sigma_r) \in \mathbb{R}^{r\times r},$$

where $\sigma_1 \geq \sigma_2 \geq \ldots \geq \sigma_r > 0$ and the columns of $\hat{U} = [\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_r] \in \mathbb{C}^{m\times r}$ and the columns of $\hat{V} = [\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_r] \in \mathbb{C}^{n\times r}$ are both orthonormal.

(See Chapter 24 for more information on singular value decomposition.)

Facts:

All the following facts except those with a specific reference can be found in [TB97, pp. 25–37].

1. Every $A \in \mathbb{C}^{m\times n}$ has a singular value decomposition $A = U\Sigma V^*$. If $A \in \mathbb{R}^{m\times n}$, then U and V may be taken to be real.
2. The singular values of a matrix are uniquely determined.
3. If $A \in \mathbb{C}^{m\times n}$ has a singular value decomposition $A = U\Sigma V^*$, then
$$A\mathbf{v}_j = \sigma_j \mathbf{u}_j, \quad A^*\mathbf{u}_j = \sigma_j \mathbf{v}_j, \quad \mathbf{u}_j^* A \mathbf{v}_j = \sigma_j,$$
for $j = 1, 2, \ldots, p = \min\{m, n\}$.
4. If $U\Sigma V^*$ is a singular value decomposition of A, then $V\Sigma^T U^*$ is a singular value decomposition of A^*.
5. If $A \in \mathbb{C}^{m\times n}$ has r nonzero singular values, then
   (a) $\operatorname{rank}(A) = r$.
   (b) $A = \sum_{j=1}^{r} \sigma_j \mathbf{u}_j \mathbf{v}_j^*$.
   (c) $\ker(A) = \operatorname{span}\{\mathbf{v}_{r+1}, \ldots, \mathbf{v}_n\}$.
   (d) $\operatorname{range}(A) = \operatorname{span}\{\mathbf{u}_1, \ldots, \mathbf{u}_r\}$.
6. Any $A \in \mathbb{C}^{m\times n}$ of rank $r \leq p = \min\{m, n\}$ has a **reduced singular value decomposition**,
$$A = \hat{U}\hat{\Sigma}\hat{V}^*, \quad \hat{\Sigma} = \operatorname{diag}(\sigma_1, \sigma_2, \ldots, \sigma_r) \in \mathbb{R}^{r\times r},$$
where $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_r > 0$ and the columns of $\hat{U} = [\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_r] \in \mathbb{C}^{m\times r}$ and the columns of $\hat{V} = [\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_r] \in \mathbb{C}^{n\times r}$ are both orthonormal. If $A \in \mathbb{R}^{m\times n}$, then $\hat{U}$ and $\hat{V}$ may be taken to be real.
7. If $\operatorname{rank}(A) = r$, then A has r nonzero singular values.
8. The nonzero singular values of A are the square roots of the nonzero eigenvalues of A^*A or AA^*.
9. [HJ85, p. 414] If $U\Sigma V^*$ is a singular value decomposition of A, then the columns of V are eigenvectors of A^*A; the columns of U are eigenvectors of AA^*.
10. [HJ85, p. 418] Let $A \in \mathbb{C}^{m\times n}$ and $p = \min\{m, n\}$. Define
$$G = \begin{bmatrix} 0 & A \\ A^* & 0 \end{bmatrix} \in \mathbb{C}^{(m+n)\times(m+n)}.$$
If the singular values of A are $\sigma_1, \ldots, \sigma_p$, then the eigenvalues of G are $\sigma_1, \ldots, \sigma_p$, $-\sigma_1, \ldots, -\sigma_p$ and additional $|n - m|$ zeros.
11. If $A \in \mathbb{C}^{n\times n}$ is Hermitian with eigenvalues $\lambda_1, \lambda_2, \cdots, \lambda_n$, then the singular values of A are $|\lambda_1|, |\lambda_2|, \cdots, |\lambda_n|$.
12. For $A \in \mathbb{C}^{n\times n}$, $|\det A| = \sigma_1\sigma_2\cdots\sigma_n$.
13. [Aut15; Sch07] (*Eckart–Young Low Rank Approximation Theorem*)
Let $A = U\Sigma V^*$ be an SVD of $A \in \mathbb{C}^{m\times n}$ and $r = \operatorname{rank}(A)$. For $k < r$, define $A_k = \sum_{j=1}^{k} \sigma_j \mathbf{u}_j \mathbf{v}_j^*$. Then
   (a) $\|A - A_k\|_2 = \min_{\operatorname{rank}(B)\leq k} \|A - B\|_2 = \sigma_{k+1}$;
   (b) $\|A - A_k\|_F = \min_{\operatorname{rank}(B)\leq k} \|A - B\|_F = \sqrt{\sum_{j=k+1}^{r} \sigma_j^2}$,

where $\|M\|_2 = \max_{||x||_2=1} ||Mx||_2$ and $\|M\|_F = \sqrt{\sum_{i=1}^{m}\sum_{j=1}^{n} m_{ij}^2}$ are the 2-norm and Frobenius norm of matrix M, respectively. (See Chapter 50 for more information on matrix norms.)

14. [HJ91, p. 152] Let $A \in \mathbb{C}^{m\times n}$. Then the singular value decomposition of A leads to the following so-called polar decomposition:
    (a) If $m \geq n$, then $A = UP$, where $U \in \mathbb{C}^{m\times n}$ has orthonormal columns and $P \in \mathbb{C}^{n\times n}$ is a positive semidefinite matrix such that $P^2 = A^*A$.
    (b) If $m \leq n$, then $A = QV$, where $V \in \mathbb{C}^{m\times n}$ has orthonormal rows and $Q \in \mathbb{C}^{m\times m}$ is a positive semidefinite matrix such that $Q^2 = AA^*$.
15. [Coo10, p. 213] (Singular value decomposition of a linear operator) Let H and K be inner product spaces of dimensions n and m, respectively. Let $T \in L(H,K)$. Then there exist unique positive numbers $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_r$ ($r \leq \min\{m,n\}$), an orthonormal basis $(\mathbf{h}_1, \mathbf{h}_2, \cdots, \mathbf{h}_n)$ for H, and an orthonormal basis $(\mathbf{k}_1, \mathbf{k}_2, \cdots, \mathbf{k}_m)$ for K such that
$$T(\mathbf{h}_j) = \sigma_j \mathbf{k}_j, \quad \text{for} \quad j = 1, 2, \cdots r,$$
and $T(\mathbf{h}_j) = \mathbf{0}$, for $j = r+1, \cdots, n$.

Examples:

Consider the matrices $A = \begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix}$ and $B = A^T = \begin{bmatrix} 1 & 2 & 0 \\ 2 & 0 & 2 \end{bmatrix}$.

1. The eigenvalues of $A^TA = \begin{bmatrix} 5 & 2 \\ 2 & 8 \end{bmatrix}$ are 9 and 4. So, the singular values of A are 3 and 2.
2. Normalized eigenvectors for A^TA are $\mathbf{v}_1 = \begin{bmatrix} \frac{1}{\sqrt{5}} \\ \frac{2}{\sqrt{5}} \end{bmatrix}$ and $\mathbf{v}_2 = \begin{bmatrix} \frac{2}{\sqrt{5}} \\ -\frac{1}{\sqrt{5}} \end{bmatrix}$.
3. $\mathbf{u}_1 = \frac{1}{3}A\mathbf{v}_1 = \begin{bmatrix} \frac{\sqrt{5}}{3} \\ \frac{2}{3\sqrt{5}} \\ \frac{4}{3\sqrt{5}} \end{bmatrix}$ and $\mathbf{u}_2 = \frac{1}{2}A\mathbf{v}_2 = \begin{bmatrix} 0 \\ \frac{2}{\sqrt{5}} \\ -\frac{1}{\sqrt{5}} \end{bmatrix}$. Application of the Gram–Schmidt process to $\mathbf{u}_1$, $\mathbf{u}_2$, and $\mathbf{e}_1$ produces $\mathbf{u}_3 = \begin{bmatrix} \frac{2}{3} \\ -\frac{1}{3} \\ -\frac{2}{3} \end{bmatrix}$.
4. A has the singular value decomposition $A = U\Sigma V^T$, where
$$U = \frac{1}{3\sqrt{5}}\begin{bmatrix} 5 & 0 & 2\sqrt{5} \\ 2 & 6 & -\sqrt{5} \\ 4 & -3 & -2\sqrt{5} \end{bmatrix}, \quad \Sigma = \begin{bmatrix} 3 & 0 \\ 0 & 2 \\ 0 & 0 \end{bmatrix}, \quad V = \frac{1}{\sqrt{5}}\begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}.$$
5. A has the reduced singular value decomposition $A = \hat{U}\hat{\Sigma}\hat{V}^T$, where
$$\hat{U} = \frac{1}{3\sqrt{5}}\begin{bmatrix} 5 & 0 \\ 2 & 6 \\ 4 & -3 \end{bmatrix}, \quad \hat{\Sigma} = \begin{bmatrix} 3 & 0 \\ 0 & 2 \end{bmatrix}, \quad \hat{V} = \frac{1}{\sqrt{5}}\begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}.$$
6. B has the singular value decomposition $B = U_B\Sigma_B V_B^T$, where
$$U_B = V_A = \frac{1}{\sqrt{5}}\begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}, \quad \Sigma_B = \begin{bmatrix} 3 & 0 & 0 \\ 0 & 2 & 0 \end{bmatrix}, \quad V_B = U_A = \frac{1}{3\sqrt{5}}\begin{bmatrix} 5 & 0 & 2\sqrt{5} \\ 2 & 6 & -\sqrt{5} \\ 4 & -3 & -2\sqrt{5} \end{bmatrix}.$$
($U_A = U$ and $V_A = V$ for A were given in Example 4.)

5.7 Pseudo-Inverse

Definitions:

A **Moore–Penrose pseudo-inverse** of a matrix $A \in \mathbb{C}^{m\times n}$ is a matrix $A^\dagger \in \mathbb{C}^{n\times m}$ that satisfies the following four **Penrose** conditions:

$$AA^\dagger A = A; \quad A^\dagger AA^\dagger = A^\dagger; \quad (AA^\dagger)^* = AA^\dagger; \quad (A^\dagger A)^* = A^\dagger A.$$

Facts:

All the following facts except those with a specific reference can be found in [Gra83, pp. 105–141] or [RM71, pp. 44–67].

1. Every $A \in \mathbb{C}^{m\times n}$ has a unique pseudo-inverse $A^\dagger$.
2. If $A \in \mathbb{R}^{m\times n}$, then $A^\dagger$ is real.
3. If $A \in \mathbb{C}^{m\times n}$ of rank r has a full rank decomposition $A = BC$, where $B \in \mathbb{C}^{m\times r}$ and $C \in \mathbb{C}^{r\times n}$, then $A^\dagger$ can be evaluated using $A^\dagger = C^*(B^*AC^*)^{-1}B^*$.
4. [LH95, p. 38] If $A \in \mathbb{C}^{m\times n}$ of rank $r \le \min\{m,n\}$ has an SVD $A = U\Sigma V^*$, then its pseudo-inverse is $A^\dagger = V\Sigma^\dagger U^*$, where
$$\Sigma^\dagger = \mathrm{diag}(1/\sigma_1, \dots, 1/\sigma_r, 0, \dots, 0) \in \mathbb{R}^{n\times m}.$$
5. [Hig96, p. 412] The pseudo-inverse $A^\dagger$ of $A \in F^{m\times n}$ ($F = \mathbb{C}$ or $\mathbb{R}$) solves the minimization problem
$$\min_{X\in F^{n\times m}} \|AX - I_m\|_F^2.$$
6. $\mathbf{0}_{mn}^\dagger = \mathbf{0}_{nm}$ and $J_{mn}^\dagger = \frac{1}{mn}J_{nm}$, where $\mathbf{0}_{mn} \in \mathbb{C}^{m\times n}$ is the all 0s matrix and $J_{mn} \in \mathbb{C}^{m\times n}$ is the all 1s matrix.
7. If $\mathbf{x} \neq \mathbf{0}$, $\mathbf{y} \neq \mathbf{0}$, then $(\mathbf{x}\mathbf{y}^*)^\dagger = \dfrac{\mathbf{y}\mathbf{x}^*}{\|\mathbf{x}\|^2\|\mathbf{y}\|^2}$.
8. If $\mathbf{x} \neq \mathbf{0}$, then $\mathbf{x}^\dagger = \dfrac{\mathbf{x}^*}{\|\mathbf{x}\|^2}$.
9. Let α be a scalar. Denote
$$\alpha^\dagger = \begin{cases} \alpha^{-1}, & \text{if } \alpha \neq 0, \\ 0, & \text{if } \alpha = 0. \end{cases}$$
Then
   (a) $(\alpha A)^\dagger = \alpha^\dagger A^\dagger$.
   (b) $(\mathrm{diag}(\beta_1, \beta_2, \cdots, \beta_n))^\dagger = \mathrm{diag}(\beta_1^\dagger, \beta_2^\dagger, \cdots, \beta_n^\dagger)$.
10. $(A^\dagger)^* = (A^*)^\dagger$; $(A^\dagger)^\dagger = A$.
11. If A is a nonsingular square matrix, then $A^\dagger = A^{-1}$.
12. If U has orthonormal columns or orthonormal rows, then $U^\dagger = U^*$.
13. If $A = A^*$ and $A = A^2$, then $A^\dagger = A$.
14. $A^\dagger = A^*$ if and only if A^*A is idempotent.
15. If A is normal and k is a positive integer, then $AA^\dagger = A^\dagger A$ and $(A^k)^\dagger = (A^\dagger)^k$.
16. If $U \in \mathbb{C}^{m\times n}$ is of rank n and satisfies $U^\dagger = U^*$, then U has orthonormal columns.
17. If $U \in \mathbb{C}^{m\times m}$ and $V \in \mathbb{C}^{n\times n}$ are unitary matrices, then $(UAV)^\dagger = V^*A^\dagger U^*$.
18. $A^\dagger = (A^*A)^\dagger A^* = A^*(AA^*)^\dagger$. In particular,
   (a) if $A \in \mathbb{C}^{m\times n}$ ($m \ge n$) has full rank n, then $A^\dagger = (A^*A)^{-1}A^*$;
   (b) if $A \in \mathbb{C}^{m\times n}$ ($m \le n$) has full rank m, then $A^\dagger = A^*(AA^*)^{-1}$.
19. Let $A \in \mathbb{C}^{m\times n}$. Then

   (a) $A^\dagger A$, $AA^\dagger$, $I_n - A^\dagger A$, and $I_m - AA^\dagger$ are orthogonal projections.

   (b) $\text{rank}(A) = \text{rank}(A^\dagger) = \text{rank}(AA^\dagger) = \text{rank}(A^\dagger A)$.

   (c) $\text{rank}(I_n - A^\dagger A) = n - \text{rank}(A)$.

   (d) $\text{rank}(I_m - AA^\dagger) = m - \text{rank}(A)$.

20. $AA^\dagger = \text{Proj}_{\text{range}(A)}$; $A^\dagger A = \text{Proj}_{\text{range}(A^\dagger)}$.
21. Suppose that $A \in F^{m\times n}$, where $F = \mathbb{C}$ or $\mathbb{R}$. Then

   (a) $\text{range}(A) = \text{range}(AA^*) = \text{range}(AA^\dagger)$.

   (b) $\text{range}(A^\dagger) = \text{range}(\text{A}^*) = \text{range}(A^*A) = \text{range}(A^\dagger A)$.

   (c) $\ker(A) = \ker(\text{A}^*\text{A}) = \ker(A^\dagger A)$.

   (d) $\ker(A^\dagger) = \ker(\text{A}^*) = \ker(AA^*) = \ker(AA^\dagger)$.

   (e) $\text{range}(A^\dagger A) \oplus \ker(A^\dagger A) = F^n$.

   (f) $\text{range}(AA^\dagger) \oplus \ker(AA^\dagger) = F^m$.

22. If $A = A_1 + A_2 + \cdots + A_k$, $A_i^* A_j = 0$, and $A_i A_j^* = 0$, for all $i, j = 1, \cdots, k$, $i \neq j$, then $A^\dagger = A_1^\dagger + A_2^\dagger + \cdots + A_k^\dagger$.
23. If A is an $m\times r$ matrix of rank r and B is an $r\times n$ matrix of rank r, then $(AB)^\dagger = B^\dagger A^\dagger$.
24. $(A^*A)^\dagger = A^\dagger (A^*)^\dagger$; $(AA^*)^\dagger = (A^*)^\dagger A^\dagger$.
25. [Gre66] Each one of the following conditions is necessary and sufficient for $(AB)^\dagger = B^\dagger A^\dagger$:

   (a) $\text{range}(BB^*A^*) \subseteq \text{range}(A^*)$ and $\text{range}(A^*AB) \subseteq \text{range}(B)$.

   (b) $A^\dagger ABB^*$ and $A^*ABB^\dagger$ are both Hermitian matrices.

   (c) $A^\dagger ABB^*A^* = BB^*A^*$ and $BB^\dagger A^*AB = A^*AB$.

   (d) $A^\dagger ABB^*A^*ABB^\dagger = BB^*A^*A$.

   (e) $A^\dagger AB = B(AB)^\dagger AB$ and $BB^\dagger A^* = A^*AB(AB)^\dagger$.

26. $(A \otimes B)^\dagger = A^\dagger \otimes B^\dagger$, where $\otimes$ denotes the Kronecker product.
27. $A^\dagger = \lim\limits_{\alpha\to 0} A^*(\alpha I + AA^*)^{-1} = \lim\limits_{\alpha \to 0}(\alpha I + A^*A)^{-1}A^*$.
28. $A^\dagger = \sum\limits_{j=1}^{\infty} A^*(I + AA^*)^{-j} = \sum\limits_{j=1}^{\infty}(I + A^*A)^{-j}A^*$.
29. (Continuity of pseudo-inverse) Suppose that $A \in F^{m\times n}$ and $E \in F^{m\times n}$, where $F = \mathbb{C}$ or $\mathbb{R}$. Then $\lim\limits_{E\to 0}(A + E)^\dagger = A^\dagger$ if and only if there is $\epsilon > 0$ such that $\text{rank}(A+E) = \text{rank(A)}$ when $\|E\|_2 \leq \epsilon$.
30. Let $A \in \mathbb{C}^{m\times n}$ be of rank r where $0 < r < \min\{m, n\}$. Suppose that A can be partitioned as

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix},$$

where $A_{11} \in \mathbb{C}^{r\times r}$ and $\text{rank}(A_{11}) = r$. Then

$$A^\dagger = \begin{bmatrix} A_{11}^* X A_{11}^* & A_{11}^* X A_{21}^* \\ A_{12}^* X A_{11}^* & A_{12}^* X A_{21}^* \end{bmatrix},$$

where

$$X = (A_{11}A_{11}^* + A_{12}A_{12}^*)^{-1}A_{11}(A_{11}^*A_{11} + A_{21}^*A_{21})^{-1}.$$

31. Penrose's algorithm for computing $A^\dagger$:

```
Algorithm 3
input: matrix $A \in \mathbb{C}^{m \times n}$ of rank $r$
output : $A^\dagger$
    choose $Y_1 = I_n$ and compute $B = A^* A$;
    compute $Y_{k+1} = \frac{\mathrm{tr}(Y_k B)}{k} I_n - Y_k B$ for $k = 1, 2, \cdots, r-1$;
    compute $\frac{r}{\mathrm{tr}(Y_r B)} Y_r A^*$. This is $A^\dagger$.
```

32. In Algorithm 3, $Y_{r+1}B = \mathbf{0}_{nn}$ and $\mathrm{tr}(Y_r B) \neq 0$. This fact can be used as the termination criterion so that $\mathrm{rank}(A)$ does not need to be known in advance.
33. Let $A \in F^{m \times n}$ and $\mathbf{b} \in F^m$, where $F = \mathbb{C}$ or $\mathbb{R}$. Then the system of equations $A\mathbf{x} = \mathbf{b}$ is consistent if and only if $AA^\dagger\mathbf{b} = \mathbf{b}$. Moreover, if $A\mathbf{x} = \mathbf{b}$ is consistent, then any solution to the system can be expressed as $\mathbf{x} = A^\dagger\mathbf{b} + (I_n - A^\dagger A)\mathbf{y}$ for some $\mathbf{y} \in F^n$.

Examples:

1. The pseudo-inverse of the matrix $A = \begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix}$ is $A^\dagger = \frac{1}{18}\begin{bmatrix} 2 & 8 & -2 \\ 4 & -2 & 5 \end{bmatrix}$.

2. $(AB)^\dagger = B^\dagger A^\dagger$ generally does not hold. For example, if

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix},$$

then

$$(AB)^\dagger = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}^\dagger = \frac{1}{2}\begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix}.$$

However,

$$B^\dagger A^\dagger = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}.$$

5.8 Least Squares Problems

Definitions:

Given $A \in F^{m \times n}$ ($F = \mathbb{R}$ or $\mathbb{C}$), $m \geq n$, and $\mathbf{b} \in F^m$, the **least squares problem** is to find an $\mathbf{x}_0 \in F^n$ such that $\|\mathbf{b} - A\mathbf{x}\|$ is minimized: $\|\mathbf{b} - A\mathbf{x}_0\| = \min_{\mathbf{x} \in F^n} \|\mathbf{b} - A\mathbf{x}\|$.

- Such an $\mathbf{x}_0$ is called a **solution** to the least squares problem or a **least squares solution** to the linear system $A\mathbf{x} = \mathbf{b}$.
- The vector $\mathbf{r} = \mathbf{b} - A\mathbf{x} \in F^m$ is called the **residual**.
- If $\mathrm{rank}(A) = n$, then the least squares problem is called the **full rank least squares problem**.
- If $\mathrm{rank}(A) < n$, then the least squares problem is called the **rank–deficient least squares problem**.

The system $A^*A\mathbf{x} = A^*\mathbf{b}$ is called the **normal equation** for the least squares problem.

(See Chapter 52 for more information on least squares problems.)

Facts: In the following facts, we assume that $A \in F^{m\times n}$ ($F = \mathbb{R}$ or $\mathbb{C}$, $m \geq n$) and $\mathbf{b} \in F^m$ are given.

1. [Mey00, p. 439] The following statements are equivalent:
   (a) $\mathbf{x}_0$ is a solution for the least squares problem.
   (b) $\min\limits_{\mathbf{x}\in F^n} \|\mathbf{b} - A\mathbf{x}\| = \|\mathbf{b} - A\mathbf{x}_0\|$.
   (c) $A\mathbf{x}_0 = P\mathbf{b}$, where P is the orthogonal projection onto range(A).
   (d) $A^*\mathbf{r}_0 = \mathbf{0}$, where $\mathbf{r}_0 = \mathbf{b} - A\mathbf{x}_0$.
   (e) $A^*A\mathbf{x}_0 = A^*\mathbf{b}$.
   (f) $\mathbf{x}_0 = A^\dagger\mathbf{b} + \mathbf{y}_0$ for some $\mathbf{y}_0 \in \ker(A)$.
2. [Mey00, p. 237] $\mathbf{x}_0$ and $\mathbf{r}_0 = \mathbf{b} - A\mathbf{x}_0$ are a solution for the least squares problem and its corresponding residual, respectively, if and only if $\mathbf{r}_0$ and $\mathbf{x}_0$ solve the consistent system

$$\begin{bmatrix} I & A \\ A^* & 0 \end{bmatrix} \begin{bmatrix} \mathbf{r} \\ \mathbf{x} \end{bmatrix} = \begin{bmatrix} \mathbf{b} \\ \mathbf{0} \end{bmatrix}.$$

   This system is called the Karush–Kuhn–Tucker equations or the augmented system associated with the least squares problem.
3. [LH95, p. 39] The general solution to the least squares problem can be expressed as $\mathbf{x} = A^\dagger\mathbf{b} + (I_n - A^\dagger A)\mathbf{y}$ for some $\mathbf{y} \in F^n$.
4. [LH95, p. 36] $\mathbf{x}_0 = A^\dagger\mathbf{b}$ is the unique solution of minimum length for the least squares problem.
5. [TB97, p. 81] If A has full rank n, then $\mathbf{x}_0 = A^\dagger\mathbf{b} = (A^*A)^{-1}A^*\mathbf{b}$ is the unique solution for the least squares problem.
6. [TB97, p. 83]

```
Algorithm 4: Solving Full Rank Least Squares via QR Factorization
input: matrix $A \in F^{m\times n}$ ($F = \mathbb{R}$ or $\mathbb{C}$, $m \geq n$) with full rank $n$ and vector $\mathbf{b} \in F^m$
output : solution $\mathbf{x}_0$ for $\min_{\mathbf{x}\in F^n} \|\mathbf{b} - A\mathbf{x}\|$
    compute the reduced QR factorization $A = \hat{Q}\hat{R}$;
    compute the vector $\mathbf{c} = \hat{Q}^*\mathbf{b}$;
    solve $\hat{R}\mathbf{x}_0 = \mathbf{c}$ using back substitution.
```

7. [TB97, p. 84]

```
Algorithm 5: Solving Full Rank Least Squares via SVD
input: matrix $A \in F^{m\times n}$ ($F = \mathbb{R}$ or $\mathbb{C}$, $m \geq n$) with full rank $n$ and vector $\mathbf{b} \in F^m$
output : solution $\mathbf{x}_0$ for $\min_{\mathbf{x}\in F^n} \|\mathbf{b} - A\mathbf{x}\|$
    compute the reduced SVD $A = \hat{U}\hat{\Sigma}\hat{V}^*$ with $\hat{\Sigma} = \mathrm{diag}(\sigma_1, \sigma_2, \cdots, \sigma_n)$;
    compute the vector $\mathbf{c} = \hat{U}^*\mathbf{b}$;
    compute the vector $\mathbf{y}$: $y_i = c_i/\sigma_i$, $i = 1, 2, \cdots, n$;
    compute $\mathbf{x}_0 = \hat{V}\mathbf{y}$.
```

8. [TB97, p. 82]

```
Algorithm 6: Solving Full Rank Least Squares via Normal Equations
input: matrix $A \in F^{m\times n}$ ($F = \mathbb{R}$ or $\mathbb{C}, m \geq n$) with full rank $n$ and vector $\mathbf{b} \in F^m$
output : solution $\mathbf{x}_0$ for $\min_{\mathbf{x}\in F^n} \|\mathbf{b} - A\mathbf{x}\|$
        compute the matrix $A^*A$ and the vector $\mathbf{c} = A^*\mathbf{b}$;
        solve the system $A^*A\mathbf{x}_0 = \mathbf{c}$ via the Cholesky factorization.
```

9. [RM71, p. 60] The minimum norm least squares solution to the matrix equation $BXC = D$ is $X = B^\dagger DC^\dagger \in F^{m\times n}$, where $B \in F^{p\times m}, C \in F^{n\times q}, D \in F^{p\times q}$ ($F = \mathbb{R}$ or $\mathbb{C}$).

Examples:

1. Consider the inconsistent linear system $A\mathbf{x} = \mathbf{b}$, where

$$A = \begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix}.$$

Then the normal equations are given by $A^TA\mathbf{x} = A^T\mathbf{b}$, where

$$A^TA = \begin{bmatrix} 5 & 2 \\ 2 & 8 \end{bmatrix} \quad \text{and} \quad A^T\mathbf{b} = \begin{bmatrix} 5 \\ 8 \end{bmatrix}.$$

A least squares solution to the system $A\mathbf{x} = \mathbf{b}$ can be obtained via solving the normal equations:

$$\mathbf{x}_0 = (A^TA)^{-1}A^T\mathbf{b} = A^\dagger\mathbf{b} = \begin{bmatrix} 2/3 \\ 5/6 \end{bmatrix}.$$

2. We use Algorithm 4 to find a least squares solution of the system $A\mathbf{x} = \mathbf{b}$ given in Example 1. The reduced QR factorization $A = \hat{Q}\hat{R}$ found in Example 5.5.1 gives

$$\hat{Q}^T\mathbf{b} = \begin{bmatrix} \frac{1}{\sqrt{5}} & \frac{4}{3\sqrt{5}} \\ \frac{2}{\sqrt{5}} & -\frac{2}{3\sqrt{5}} \\ 0 & \frac{\sqrt{5}}{3} \end{bmatrix}^T \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} = \begin{bmatrix} \sqrt{5} \\ \sqrt{5} \end{bmatrix}.$$

Now solving $\hat{R}\mathbf{x} = [\sqrt{5}, \sqrt{5}]^T$ gives the least squares solution $\mathbf{x}_0 = [2/3, 5/6]^T$.

3. We use Algorithm 5 to solve the same problem given in Example 1. Using the reduced singular value decomposition $A = \hat{U}\hat{\Sigma}\hat{V}^T$ obtained in Example 5.6.5, we have

$$\mathbf{c} = \hat{U}^T\mathbf{b} = \frac{1}{3\sqrt{5}} \begin{bmatrix} 5 & 0 \\ 2 & 6 \\ 4 & -3 \end{bmatrix}^T \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} = \begin{bmatrix} \frac{7}{\sqrt{5}} \\ \frac{1}{\sqrt{5}} \end{bmatrix}.$$

Now we compute $\mathbf{y} = [y_1, y_2]^T$:

$$y_1 = c_1/\sigma_1 = \frac{7}{3\sqrt{5}} \quad \text{and} \quad y_2 = c_2/\sigma_2 = \frac{1}{2\sqrt{5}}.$$

Finally, the least squares solution is obtained via

$$\mathbf{x}_0 = \hat{V}\mathbf{y} = \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix} \begin{bmatrix} \frac{7}{3\sqrt{5}} \\ \frac{1}{2\sqrt{5}} \end{bmatrix} = \begin{bmatrix} 2/3 \\ 5/6 \end{bmatrix}.$$

Canonical Forms for Similarity

Leslie Hogben
Iowa State University
and American Institute of Mathematics

6.1 Generalized Eigenvectors 6-2
6.2 Jordan Canonical Form 6-3
6.3 Real-Jordan Canonical Form 6-7
6.4 Weyr Canonical Form 6-8
6.5 Rational Canonical Form: Elementary Divisors 6-11
6.6 Smith Normal Form on $F[x]^{n\times n}$ 6-14
6.7 Rational Canonical Form: Invariant Factors 6-15
References 6-18

Intuitively, a canonical form is a representative of an equivalence class that has a particularly simple form (or a form well suited to a specific purpose). More precisely, let $\mathcal{S}$ be a given set (e.g., of matrices), and let $\sim$ be an equivalence relation on $\mathcal{S}$ (e.g., similarity). For any $a \in \mathcal{S}$, let $\mathcal{S}_a = \{b \in \mathcal{S} : b \sim a\}$ denote the equivalence class that contains a. Then $\cup_{a\in\mathcal{S}}\mathcal{S}_a = \mathcal{S}$ and for each $a, b \in \mathcal{S}$, either $\mathcal{S}_a = \mathcal{S}_b$ (if $a \sim b$) or $\mathcal{S}_a \cap \mathcal{S}_b = \emptyset$ (if $a \nsim b$). Let the set $C \subset \mathcal{S}$ be a distinguished set of elements of $\mathcal{S}$, one from each equivalence class, i.e., $\cup_{a\in C}\mathcal{S}_a = \mathcal{S}$ and $\mathcal{S}_a \cap \mathcal{S}_b = \emptyset$ whenever $a, b \in C$ and $a \neq b$. For a given $a \in \mathcal{S}$, $c \in C$ is a *canonical form for a* if $\mathcal{S}_a = \mathcal{S}_c$. In this section, we are mainly concerned with the set $\mathcal{S}$ of all $n \times n$ matrices over a given field, and with the equivalence relation of similarity on $\mathcal{S}$. Additional information on canonical forms can be found in Chapter 7. Although technically a canonical form requires a unique representative of each equivalence class (of similar matrices), the term is often used more loosely, typically requiring uniqueness up to some type of permutation similarity (where it is easy to recognize when two such matrices are in the same equivalence class).

If the field is the complex numbers, we introduce the *Jordan* and *Weyr* canonical forms, each of which is well suited for application to different types of problems. The Jordan canonical form works well in problems involving primary matrix functions, e.g., powers and polynomials, while the Weyr canonical form works well in problems involving commutativity. We also consider a real version of the Jordan canonical form.

For other fields (e.g., the field $\mathbb{Q}$ of rational numbers) the *rational canonical form* is available; we discuss it in Sections 6.5 and 6.7. The Smith normal form is a canonical form for square matrices over principal ideal domains (see Chapter 32); it is discussed here only as it pertains to the computation of the rational canonical form. If any one of these canonical forms is known for a given matrix, it is straightforward to determine the others (perhaps in the algebraic closure of the field).

Results about each type of canonical form are presented in the section on that canonical form, which facilitates locating a result, but obscures the connections underlying the derivations of the results. The facts about all of the canonical forms discussed in this section can be derived from results about modules over a principal ideal domain; such a module-theoretic treatment is typically presented in abstract algebra texts, such as [DF04, Chap. 12].

None of the canonical forms discussed in this section is a continuous function of the entries of a matrix, and thus the computation of such a canonical form is inherently unstable in finite precision arithmetic. For information about perturbation theory of eigenvalues see Chapter 21; for information specifically about numerical computation of the Jordan canonical form, see [GV96, Sect. 7.6.5].

6.1 Generalized Eigenvectors

The reader is advised to consult Section 4.4 for information about eigenvalues and eigenvectors. In this section and the next, F is taken to be an algebraically closed field to ensure that an $n \times n$ matrix has n eigenvalues, but many of the results could be rephrased for a matrix that has all its eigenvalues in F, without the assumption that F is algebraically closed. The real versions of the definitions and results are presented in Section 6.3.

Definitions:

Let F be an algebraically closed field (e.g., $\mathbb{C}$), let $A \in F^{n\times n}$, let $\mu_1, \ldots, \mu_r$ be the distinct eigenvalues of A, and let λ be any eigenvalue of A.

For k a nonnegative integer, the k-**eigenspace** of A at λ, denoted $N_\lambda^k(A)$, is $\ker(A - \lambda I)^k$.

The **index** of A at λ, denoted $\nu_\lambda(A)$, is the smallest integer k such that $N_\lambda^k(A) = N_\lambda^{k+1}(A)$. When λ and A are clear from the context, $\nu_\lambda(A)$ will be abbreviated to ν, and $\nu_{\mu_i}(A)$ to ν_i.

The **generalized eigenspace** of A at λ is the set $N_\lambda^\nu(A)$, where ν is the index of A at λ.

The vector $\mathbf{x} \in F^n$ is a **generalized eigenvector** of A for λ if $\mathbf{x} \neq \mathbf{0}$ and $\mathbf{x} \in N_\lambda^\nu(A)$.

Let V be a finite dimensional vector space over F, and let T be a linear operator on V. The definitions of k-**eigenspace** of T, **index**, and **generalized eigenspace** of T are analogous.

Facts:

Facts requiring proof for which no specific reference is given can be found in [HJ13, Chap. 3] or [Mey00, Sect. 7.8].

Notation: F is an algebraically closed field, $A \in F^{n\times n}$, V is an n dimensional vector space over F, $T \in L(V, V)$, $\mu_1, \ldots, \mu_r$ are the distinct eigenvalues of A or T, and $\lambda = \mu_i$ for some $i \in \{1, \ldots, r\}$.

1. An eigenvector for eigenvalue λ is a generalized eigenvector for λ, but the converse is not necessarily true.
2. The eigenspace for λ is the 1-eigenspace, i.e., $E_\lambda(A) = N_\lambda^1(A)$.
3. Every k-eigenspace is invariant under multiplication by A.
4. The dimension of the generalized eigenspace of A at λ is the algebraic multiplicity of λ, i.e., $\dim N_{\mu_i}^{\nu_i}(A) = \alpha_A(\mu_i)$.
5. A is diagonalizable if and only if $\nu_i = 1$ for $i = 1, \ldots, r$.
6. F^n is the vector space direct sum of the generalized eigenspaces, i.e.,
$$F^n = N_{\mu_1}^{\nu_1}(A) \oplus \cdots \oplus N_{\mu_r}^{\nu_r}(A).$$
This is a special case of the Primary Decomposition Theorem (Fact 6.5.12).
7. Facts 1 to 6 remain true when the matrix A is replaced by the linear operator T.
8. If $\hat{T}$ denotes T restricted to $N_{\mu_i}^{\nu_i}(T)$, then the characteristic polynomial of $\hat{T}$ is $p_{\hat{T}}(x) = (x - \mu_i)^{\alpha(\mu_i)}$. In particular, $\hat{T} - \mu_i I$ is nilpotent.

Examples:

1. Let $A = \begin{bmatrix} 65 & 18 & -21 & 4 \\ -201 & -56 & 63 & -12 \\ 67 & 18 & -23 & 4 \\ 134 & 36 & -42 & 6 \end{bmatrix} \in \mathbb{C}^{4\times 4}$. $p_A(x) = x^4+8x^3+24x^2+32x+16 = (x+2)^4$, so the only eigenvalue of A is -2 with algebraic multiplicity 4. The reduced row echelon form of $A+2I$ is $\begin{bmatrix} 1 & \frac{18}{67} & -\frac{21}{67} & \frac{4}{67} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$, so $N_{-2}^1(A) = \text{Span}\left(\begin{bmatrix} -18 \\ 67 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 21 \\ 0 \\ 67 \\ 0 \end{bmatrix}, \begin{bmatrix} -4 \\ 0 \\ 0 \\ 67 \end{bmatrix}\right)$. $(A+2I)^2 = 0$, so $N_{-2}^2(A) = \mathbb{C}^4$. Any vector not in $N_{-2}^1(A)$, e.g., $\mathbf{e}_1 = [1,0,0,0]^T$, is a generalized eigenvector for -2 that is not an eigenvector for -2.

6.2 Jordan Canonical Form

The Jordan canonical form is perhaps the single most important and widely used similarity-based canonical form for (square) matrices.

Definitions:

Let F be an algebraically closed field (e.g., $\mathbb{C}$), and let $A \in F^{n\times n}$. (The real versions of the definitions and results are presented in Section 6.3.)

For $\lambda \in F$ and positive integer k, the **Jordan block** of size k with eigenvalue λ is the $k \times k$ matrix having every diagonal entry equal to λ, every first superdiagonal entry equal to 1, and every other entry equal to 0, i.e.,

$$J_k(\lambda) = \begin{bmatrix} \lambda & 1 & 0 & \cdots & 0 \\ 0 & \lambda & 1 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & \lambda & 1 \\ 0 & \cdots & 0 & 0 & \lambda \end{bmatrix}.$$

A **Jordan matrix** (or a **matrix in Jordan canonical form**) is a block diagonal matrix having Jordan blocks as the diagonal blocks, i.e., a matrix of the form $J_{k_1}(\lambda_1) \oplus \cdots \oplus J_{k_t}(\lambda_t)$ for some positive integers $t, k_1, \ldots, k_t$ and some $\lambda_1, \ldots, \lambda_t \in F$. (Note: the λ_i need not be distinct.)

A **Jordan canonical form** of matrix A, denoted J_A or JCF(A), is a Jordan matrix that is similar to A. It is conventional to group the blocks for the same eigenvalue together and to order the Jordan blocks with the same eigenvalue in nonincreasing size order.

The **Jordan invariants** of A are the following parameters:

- The set of distinct eigenvalues of A.
- For each eigenvalue λ, the number b_λ and sizes $p_1, \ldots, p_{b_\lambda}$ of the Jordan blocks with eigenvalue λ in a Jordan canonical form of A.

The **total number of Jordan blocks** in a Jordan canonical form of A is $\sum b_\mu$, where the sum is taken over all distinct eigenvalues μ.

If $J_A = C^{-1}AC$, then the ordered set of columns of C is called a **Jordan basis** for A.

Let $\mathbf{x}$ be an eigenvector for eigenvalue λ of A. If $\mathbf{x} \in \text{range}(A-\lambda I)^h - \text{range}(A-\lambda I)^{h+1}$. Then h is called the **depth** of $\mathbf{x}$.

Let $\mathbf{x}$ be an eigenvector of depth h for eigenvalue λ of A. A **Jordan chain** above $\mathbf{x}$ is a sequence of vectors $\mathbf{x}_0 = \mathbf{x}, \mathbf{x}_1, \ldots, \mathbf{x}_h$ satisfying $\mathbf{x}_i = (A-\lambda I)\mathbf{x}_{i+1}$ for $i = 0, \ldots, h-1$.

Let V be a finite dimensional vector space over F, and let T be a linear operator on V.

A **Jordan basis** for T is an ordered basis $\mathcal{B}$ of V, with respect to which the matrix ${}_{\mathcal{B}}[T]_{\mathcal{B}}$ of T is a Jordan matrix. In this case, ${}_{\mathcal{B}}[T]_{\mathcal{B}}$ is a Jordan canonical form of T, denoted $\mathrm{JCF}(T)$ or J_T, and the **Jordan invariants** of T are the Jordan invariants of $\mathrm{JCF}(T) ={}_{\mathcal{B}} [T]_{\mathcal{B}}$.

Facts:

Facts requiring proof for which no specific reference is given can be found in [HJ13, Chap. 3] or [Mey00, Sect. 7.8].

Notation: F is an algebraically closed field, $A, B \in F^{n\times n}$, and λ is an eigenvalue of A.

1. A has a Jordan canonical form J_A (i.e., A is similar to a Jordan matrix), and J_A is unique up to permutation of the Jordan blocks. In particular, the Jordan invariants of A are uniquely determined by A.
2. A, B are similar if and only if they have the same Jordan invariants.
3. The Jordan invariants and, hence, the Jordan canonical form of A can be found from the eigenvalues and the ranks of powers of $A - \lambda I$. Specifically, the number of Jordan blocks of size k in J_A with eigenvalue λ is
$$\operatorname{rank}(A-\lambda I)^{k-1} + \operatorname{rank}(A-\lambda I)^{k+1} - 2\operatorname{rank}(A-\lambda I)^{k}.$$
4. The total number of Jordan blocks in a Jordan canonical form of A is the maximal number of linearly independent eigenvectors of A.
5. The number b_λ of Jordan blocks with eigenvalue λ in J_A equals the geometric multiplicity $\gamma_A(\lambda)$ of λ. A is nonderogatory if and only if for each eigenvalue λ of A, J_A has exactly one block with λ.
6. The size of the largest Jordan block with eigenvalue λ equals the multiplicity of λ as a root of the minimal polynomial $q_A(x)$ of A.
7. The size of the largest Jordan block with eigenvalue λ equals the size of the index $\nu_\lambda(A)$ of A at λ.
8. The sum of the sizes of all the Jordan blocks with eigenvalue λ in J_A (i.e., the number of times λ appears on the diagonal of the Jordan canonical form) equals the algebraic multiplicity $\alpha_A(\lambda)$ of λ.
9. Knowledge of both the characteristic and minimal polynomials suffices to determine the Jordan block sizes for any eigenvalue having algebraic multiplicity at most 3 and, hence, to determine the Jordan canonical form of A if no eigenvalue of A has algebraic multiplicity exceeding 3. This is not necessarily true when the algebraic multiplicity of an eigenvalue is 4 or greater (cf. Example 3 next).
10. Knowledge of the the algebraic multiplicity, geometric multiplicity, and index of an eigenvalue λ suffices to determine the Jordan block sizes for λ if the algebraic multiplicity of λ is at most 6. This is not necessarily true when the algebraic multiplicity of an eigenvalue is 7 or greater (cf. Example 4 next).
11. The following are equivalent:
    (a) A is similar to a diagonal matrix.
    (b) The total number of Jordan blocks of A equals n.
    (c) The size of every Jordan block in a Jordan canonical form J_A of A is 1.
    (d) J_A is diagonal.
12. If A is real, then nonreal eigenvalues of A occur in conjugate pairs; furthermore, if λ is a nonreal eigenvalue, then each size k Jordan block with eigenvalue λ can be paired with a size k Jordan block for $\overline{\lambda}$.
13. If $A = A_1 \oplus \cdots \oplus A_m$, then $J_{A_1} \oplus \cdots \oplus J_{A_m}$ is a Jordan canonical form of A.

14. A and its transpose A^T have the same Jordan canonical form (and are, therefore, similar).
15. For a nilpotent matrix, the list of block sizes determines the Jordan canonical form or, equivalently, determines the similarity class. The number of similarity classes of nilpotent matrices of size n is the number of partitions of n.
16. Let J_A be a Jordan matrix, let D be the diagonal matrix having the same diagonal as J_A, and let $N = J_A - D$. Then N is nilpotent.
17. A can be expressed as the sum of a diagonalizable matrix A_D and a nilpotent matrix A_N, where A_D and A_N are polynomials in A (and A_D and A_N commute).
18. [Mey00, Sect. 7.8] A Jordan basis and Jordan canonical form of A can be constructed using Algorithm 1.

Algorithm 1: Jordan Basis and Jordan Canonical Form

```
Input: $A \in F^{n\times n}$, the distinct eigenvalues $\mu_1, \ldots, \mu_r$, the indices $\nu_1, \ldots, \nu_r$.
Output: $C \in F^{n\times n}$ such that $C^{-1}AC = J_A$.
Initially $C$ has no columns.
FOR $i = 1, \ldots, r$            % working on eigenvalue $\mu_i$
  Step 1: Find a special basis $\mathcal{B}_{\mu_i}$ for $E_{\mu_i}(A)$.
  (a) Initially $\mathcal{B}_{\mu_i}$ has no vectors.
  (b) FOR $k = \nu_i - 1$ down to 0
        Extend the set of vectors already found to a basis for range$(A-\mu_i I)^k \cap E_{\mu_i}(A)$.
  (c) Denote the vectors of $\mathcal{B}_{\mu_i}$ by $\mathbf{b}_j$ (ordered as found in Step (b)).
  Step 2: For each vector $\mathbf{b}_j$ found in Step 1, build a Jordan chain above $\mathbf{b}_j$.
  FOR $j = 1, \ldots, \dim\ker(A - \mu_i I)$            % working on $\mathbf{b}_j$
  (a) Solve $(A - \mu_i I)^{h_j}\mathbf{u}_j = \mathbf{b}_j$ for $\mathbf{u}_j$ where $h_j$ is the depth of $\mathbf{b}_j$.
  (b) Insert $(A - \mu_i I)^{h_j}\mathbf{u}_j, (A - \mu_i I)^{h_j-1}\mathbf{u}_j, \ldots, (A - \mu_i I)\mathbf{u}_j, \mathbf{u}_j$
        as the next $h + 1$ columns of $C$.
```

19. Let V be an n-dimensional vector space over F and T be a linear operator on V. Facts 1, 3 to 10, 15, and 17 remain true when matrix A is replaced by linear operator T; in particular, JCF(T) exists and is independent (up to permutation of the diagonal Jordan blocks) of the ordered basis of V used to compute it, and the Jordan invariants of T are independent of basis.

Examples:

1. $J_4(3) = \begin{bmatrix} 3 & 1 & 0 & 0 \\ 0 & 3 & 1 & 0 \\ 0 & 0 & 3 & 1 \\ 0 & 0 & 0 & 3 \end{bmatrix}.$
2. Let A be the matrix in Example 6.1.1. $p_A(x) = x^4 + 8x^3 + 24x^2 + 32x + 16 = (x+2)^4$, so the only eigenvalue of A is -2 with algebraic multiplicity 4. From Example 6.1.1, A has 3 linearly independent eigenvectors for eigenvalue -2, so J_A has 3 Jordan blocks with eigenvalue -2. In this case, this is enough information to completely determine that $J_A = \begin{bmatrix} -2 & 1 & 0 & 0 \\ 0 & -2 & 0 & 0 \\ 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & -2 \end{bmatrix}.$
3. Jordan canonical form of A is not necessarily determined by the characteristic and minimal polynmials of A. For example, the Jordan matrices $A = J_2(0) \oplus J_1(0) \oplus J_1(0)$ and $B = J_2(0) \oplus J_2(0)$ are not similar to each other, but have $p_A(x) = p_B(x) = x^4$, $q_A(x) = q_B(x) = x^2$.

4. Jordan canonical form of A is not necessarily determined by the eigenvalues and the algebraic multiplicity, geometric multiplicity, and index of each eigenvalue. For example, the Jordan matrices $A = J_3(0) \oplus J_3(0) \oplus J_1(0)$ and $B = J_3(0) \oplus J_2(0) \oplus J_2(0)$ are not similar to each other, but have $\alpha_A(0) = \alpha_B(0) = 7, \gamma_A(0) = \gamma_B(0) = 3, \nu_0(A) = \nu_0(B) = 3$ (and $p_A(x) = p_B(x) = x^7, q_A(x) = q_B(x) = x^3$).
5. We use Algorithm 1 to find a matrix C such that $C^{-1}AC = J_A$ for $A = \begin{bmatrix} -2 & 3 & 0 & 1 & -1 \\ 4 & 0 & 3 & 0 & -2 \\ 6 & -3 & 3 & -1 & -1 \\ -8 & 6 & -3 & 2 & 0 \\ 2 & 3 & 3 & 1 & -3 \end{bmatrix}$. Computations show that $p_A(x) = x^5$ and $\ker A = \text{Span}(\mathbf{z}_1, \mathbf{z}_2, \mathbf{z}_3)$, where $\mathbf{z}_1 = [3, 2, -4, 0, 0]^T, \mathbf{z}_2 = [0, 1, 0, -3, 0]^T, \mathbf{z}_3 = [3, 4, 0, 0, 6]^T$.

   For Step 1, $A^3 = \mathbf{0}$, and $\text{range}(A^2) = \text{Span}(\mathbf{b}_1)$ where $\mathbf{b}_1 = [-1, -1, 0, -1, -2]^T$.

   Then $\mathcal{B} = \{\mathbf{b}_1, \mathbf{z}_1, \mathbf{z}_2\}$ is a suitable basis (any 2 of $\{\mathbf{z}_1, \mathbf{z}_2, \mathbf{z}_3\}$ will work in this case).

   For Step 2, construct a Jordan chain above $\mathbf{b}_1$ by solving $A^2\mathbf{u}_1 = \mathbf{b}_1$. There are many possible solutions; we choose $\mathbf{u}_1 = [0, 0, 0, 0, 1]^T$. Then $A\mathbf{u}_1 = [-1, -2, -1, 0, -3]^T$,

$$C = \begin{bmatrix} -1 & -1 & 0 & 3 & 0 \\ -1 & -2 & 0 & 2 & 1 \\ 0 & -1 & 0 & -4 & 0 \\ -1 & 0 & 0 & 0 & -3 \\ -2 & -3 & 1 & 0 & 0 \end{bmatrix}, \quad \text{and} \quad J_A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \oplus [0] \oplus [0].$$

TABLE 6.1 $\text{rank}(A - \lambda I)^k$

$k =$	1	2	3	4	5
$\lambda = 1$	11	10	9	9	9
$\lambda = 2$	12	10	10	10	10
$\lambda = 3$	12	11	10	9	9

6. We compute the Jordan canonical form of a 14×14 matrix A by the method in Fact 3, where the necessary data about the eigenvalues of A and ranks is given in Table 6.1.

   $\lambda = 1$
   - The number of blocks of size 1 is $14 + 10 - 2 \cdot 11 = 2$.
   - The number of blocks of size 2 is $11 + 9 - 2 \cdot 10 = 0$.
   - The number of blocks of size 3 is $10 + 9 - 2 \cdot 9 = 1$.

   So $\nu_1 = 3$ and $b_1 = 3$.

   $\lambda = 2$
   - The number of blocks of size 1 is $14 + 10 - 2 \cdot 12 = 0$.
   - The number of blocks of size 2 is $12 + 10 - 2 \cdot 10 = 2$.

   So, $\nu_2 = 2$ and $b_2 = 2$.

   $\lambda = 3$
   - The number of blocks of size 1 is $14 + 11 - 2 \cdot 12 = 1$.
   - The number of blocks of size 2 is $12 + 10 - 2 \cdot 11 = 0$.
   - The number of blocks of size 3 is $11 + 9 - 2 \cdot 10 = 0$.
   - The number of blocks of size 4 is $10 + 9 - 2 \cdot 9 = 1$.

   So, $\nu_3 = 4$ and $b_3 = 2$.

   From this information,

$$J_A = J_3(1) \oplus J_1(1) \oplus J_1(1) \oplus J_2(2) \oplus J_2(2) \oplus J_4(3) \oplus J_1(3).$$

6.3 Real-Jordan Canonical Form

The real-Jordan canonical form is used in applications to differential equations, dynamical systems, and control theory (see Chapter 79). The real-Jordan canonical form is discussed here only for matrices and with limited discussion of generalized eigenspaces; more generality is possible, and is readily derivable from the corresponding results for the Jordan canonical form.

Definitions:

Let $A \in \mathbb{R}^{n\times n}, \alpha, \beta, \alpha_j, \beta_j \in \mathbb{R}$.

The **real generalized eigenspace** of A at eigenvalue $\alpha + \beta i$ is

$$E(A, \alpha+\beta i) = \begin{cases} \ker((A^2 - 2\alpha A + (\alpha^2+\beta^2)I)^\nu) & \text{if } \beta \neq 0 \\ N_\alpha^\nu(A) = \ker((A-\alpha I)^\nu) & \text{if } \beta = 0. \end{cases}$$

The vector $\mathbf{x} \in \mathbb{R}^n$ is a **real generalized eigenvector** of A for $\alpha + \beta i$ if $\mathbf{x} \neq \mathbf{0}$ and $\mathbf{x} \in E(A, \alpha+\beta i)$.

For $\alpha, \beta \in \mathbb{R}$ with $\beta \neq 0$, and even positive integer $2k$, the **real-Jordan block** of size $2k$ with eigenvalue $\alpha + \beta i$ is the $2k \times 2k$ matrix having k copies of $M_2(\alpha,\beta) = \begin{bmatrix} \alpha & \beta \\ -\beta & \alpha \end{bmatrix}$ on the (block matrix) diagonal, $k-1$ copies of $I_2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ on the first (block matrix) superdiagonal, and copies of $0_2 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$ everywhere else, i.e.,

$$J_{2k}^{\mathbb{R}}(\alpha+\beta i) = \begin{bmatrix} M_2(\alpha,\beta) & I_2 & 0_2 & \cdots & 0_2 \\ 0_2 & M_2(\alpha,\beta) & I_2 & \cdots & 0_2 \\ \vdots & \ddots & \ddots & & \vdots \\ 0_2 & \cdots & 0_2 & M_2(\alpha,\beta) & I_2 \\ 0_2 & \cdots & 0_2 & 0_2 & M_2(\alpha,\beta) \end{bmatrix}.$$

A **real-Jordan matrix** (or a **matrix in real-Jordan canonical form**) is a block diagonal matrix having diagonal blocks that are Jordan blocks or real-Jordan blocks, i.e., a matrix of the form $J_{m_1}(\alpha_1) \oplus \cdots \oplus J_{m_t}(\alpha_t) \oplus J_{2k_{t+1}}^{\mathbb{R}}(\alpha_{t+1} + \beta_{t+1} i) \oplus \cdots \oplus J_{2k_s}^{\mathbb{R}}(\alpha_s + \beta_s i)$ (or a permutation of the direct summands).

A **real-Jordan canonical form** of matrix A, denoted $J_A^{\mathbb{R}}$ or $\mathrm{JCF}^{\mathbb{R}}(A)$, is a real-Jordan matrix that is similar to A. It is conventional to use $\beta_j > 0$, to group the blocks for the same eigenvalue together, and to order the Jordan blocks with the same eigenvalue in nonincreasing size order.

The **total number of Jordan blocks** in a real-Jordan canonical form of A is the number of blocks (Jordan or real-Jordan) in $J_A^{\mathbb{R}}$.

Facts:

Facts requiring proof without a specific reference given can be found in [HJ13, Chap. 3].

Notation: $A, B \in \mathbb{R}^{n\times n}, \alpha, \beta, \alpha_j, \beta_j \in \mathbb{R}$.

1. The real generalized eigenspace of a complex number $\lambda = \alpha + \beta i$ and its conjugate $\overline{\lambda} = \alpha - \beta i$ are equal, i.e., $E(A, \alpha+\beta i) = E(A, \alpha - \beta i)$.
2. The real-Jordan blocks with a nonreal complex number and its conjugate are similar to each other.
3. A has a real-Jordan canonical form $J_A^{\mathbb{R}}$. Provided the real-Jordan blocks $J_{2k}^{\mathbb{R}}(\alpha+\beta i)$ are chosen with $\beta > 0$, $J_A^{\mathbb{R}}$ is unique up to permutation of the diagonal (real-) Jordan blocks.

4. Provided the real-Jordan blocks $J^{\mathbb{R}}_{2k}(\alpha+\beta i)$ are chosen with $\beta > 0$, A, B are similar if and only if their real-Jordan canonical forms are the same up to the order of their Jordan and real-Jordan blocks.
5. If all the eigenvalues of A are real, then $J^{\mathbb{R}}_A$ is the same as J_A (up to the order of the Jordan blocks).
6. The real-Jordan canonical form of A can be computed from the Jordan canonical form of A. The nonreal eigenvalues occur in conjugate pairs, and if $\beta > 0$, then each size k Jordan block with eigenvalue $\alpha+\beta i$ can be paired with a size k Jordan block for $\alpha-\beta i$. Then $J_k(\alpha+\beta i)\oplus J_k(\alpha-\beta i)$ is replaced by $J^{\mathbb{R}}_{2k}(\alpha+\beta i)$. The Jordan blocks of $J^{\mathbb{R}}_A$ with real eigenvalues are the same as those of J_A.
7. The total number of Jordan and real-Jordan blocks in a real-Jordan canonical form of A is the number of Jordan blocks with a real eigenvalue plus half the number of Jordan blocks with a nonreal eigenvalue in a Jordan canonical form of A.
8. If $\beta \neq 0$, the size of the largest real-Jordan block with eigenvalue $\alpha+\beta i$ is twice the multiplicity of $x^2 - 2\alpha x + (\alpha^2+\beta^2)$ as a factor of the minimal polynomial $q_A(x)$ of A.
9. If $\beta \neq 0$, the sum of the sizes of all the real-Jordan blocks with eigenvalue $\alpha+\beta i$ in J_A equals twice the algebraic multiplicity $\alpha_A(\alpha+\beta i)$.
10. If $\beta \neq 0$, $\dim E(A, \alpha+\beta i) = \alpha_A(\alpha+\beta i)$.
11. If $A = A_1 \oplus \cdots \oplus A_m$, then $J^{\mathbb{R}}_{A_1} \oplus \cdots \oplus J^{\mathbb{R}}_{A_m}$ is a real-Jordan canonical form of A.

Examples:

1. Let $a = \begin{bmatrix} -10 & 6 & -4 & 4 & 0 \\ -17 & 10 & -4 & 6 & -1 \\ -4 & 2 & -3 & 2 & 1 \\ -11 & 6 & -11 & 6 & 3 \\ -4 & 2 & -4 & 2 & 2 \end{bmatrix}$. Since the characteristic and minimal polynomials of A are both $x^5 - 5x^4 + 12x^3 - 16x^2 + 12x - 4 = (x-1)\left(x^2 - 2x + 2\right)^2$,
$$J^{\mathbb{R}}_A = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 \\ -1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$
2. The requirement that $\beta \neq 0$ is important. $A = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ is *not* a real-Jordan matrix;
$$J_A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

6.4 Weyr Canonical Form

Definitions:

Let F be an algebraically closed field (e.g., $\mathbb{C}$), $A \in F^{n\times n}$, and let $\lambda \in F$ be an eigenvalue of A.

Define

$$w_k(A,\lambda) = \operatorname{rank}(A-\lambda I)^{k-1} - \operatorname{rank}(A-\lambda I)^k,\ k = 1,2,\dots,\nu_\lambda(A);$$

note that $w_1(A,\lambda) = n - \operatorname{rank}(A-\lambda I)$. The sequence $w(A,\lambda) = (w_1(A,\lambda),\dots,w_{\nu_\lambda(A)}(A,\lambda))$ is the **Weyr characteristic of A associated with λ.**

The **Weyr block $W_A(\lambda)$ of A associated with λ** is

$$W_A(\lambda) = \begin{bmatrix} \lambda I_{w_1} & G_{w_1,w_2} & & & \\ & \lambda I_{w_2} & G_{w_2,w_3} & & \\ & & \ddots & \ddots & \\ & & & \ddots & G_{w_{\nu-1},w_\nu} \\ & & & & \lambda I_{w_\nu} \end{bmatrix}$$

in which $w_k = w_k(A,\lambda)$, $k = 1,2,\dots,\nu$, $\nu = \nu_\lambda(A)$ is the index of A at λ, and

$$G_{w_i,w_j} = \begin{bmatrix} I_{w_j} \\ 0 \end{bmatrix} \in F^{w_i\times w_j}, \quad 1 \le i < j$$

A **Weyr matrix** is a direct sum of Weyr blocks with distinct eigenvalues.

A **Weyr canonical form of** A is the Weyr matrix $W_A(\lambda_1)\oplus\cdots\oplus W_A(\lambda_d)$, in which $\lambda_1,\dots,\lambda_d$ are the distinct eigenvalues of A in any desired order.

Facts:

Facts requiring proof for which no specific reference is given can be found in [HJ13, Sects. 3.4.2 and 3.4.3].

Notation: F is an algebraically closed field (e.g., $\mathbb{C}$), $A \in F^{n\times n}$, and $\lambda \in F$ is an eigenvalue of A.

1. A has a Weyr canonical form W_A (i.e., A is similar to a Weyr matrix), and W_A is unique up to the order of the eigenvalues (i.e., up to a permutation of the Weyr blocks).
2. A unique Weyr matrix to which A is similar may be obtained, for example, by imposing the lexicographical order $\lambda_1 \preccurlyeq \cdots \preccurlyeq \lambda_d$, in which $a+ib \preccurlyeq c+id$ if either $a < c$ or $a = c$ and $b \le d$.
3. $B \in F^{n\times n}$ is similar to A if and only if A and B have the same sets of distinct eigenvalues, and the Weyr characteristics of A and B associated with each distinct eigenvalue are the same.
4. In the Weyr characteristic $w(A,\lambda) = (w_1(A,\lambda),\dots,w_{\nu_\lambda(A)}(A,\lambda))$ of A for λ:
   (a) $w_k(A,\lambda)$ is the number of Jordan blocks of A of size at least k.
   (b) A has exactly $w_k(A,\lambda)-w_{k+1}(A,\lambda)$ Jordan blocks $J_k(\lambda)$ in its Jordan canonical form.
   (c) $w_1(A,\lambda) \ge \cdots \ge w_{\nu_\lambda(A)}(A,\lambda)$
   (d) $w_1(A,\lambda)$ is the geometric multiplicity of λ as an eigenvalue of A.
   (e) $w_1(A,\lambda)+\cdots+w_{\nu_\lambda(A)}(A,\lambda)$ is the algebraic multiplicity of λ as an eigenvalue of A.
5. Jordan and Weyr canonical forms of A are permutation similar.
6. A is nonderogatory if and only if $w_1(A,\lambda) = 1$ for every eigenvalue λ of A.
7. Jordan and Weyr canonical forms of a nonderogatory matrix are the same (up to the order of the blocks).

8. A is diagonalizable if and only if $w_2(A, \lambda) = 0$ for every eigenvalue λ of A.
9. Jordan and Weyr canonical forms of a diagonalizable matrix are the same (up to the order of the diagonal entries).
10. [HJ13, Problem 11 in Sect. 3.4] Jordan and Weyr canonical forms of A are the same (up to the order of the blocks) if and only if
    (a) A is nonderogatory, or
    (b) A is diagonalizable, or
    (c) there are matrices B and C such that
        (i) B is nonderogatory, and
        (ii) C is diagonalizable, and
        (iiii) B and C have no eigenvalues in common, and
        (iv) A is similar to $B \oplus C$.
11. A matrix that commutes with a Weyr matrix is block upper triangular, and its constituent blocks have a special structure; see [HJ13, Theorem 3.4.2.10]. A matrix that commutes with a Jordan matrix need not be block upper triangular; see Example 2.
12. Let $\mathcal{F} = \{A, A_1, A_2, \ldots\} \subset F^{n\times n}$ be a commuting family of matrices. There is a nonsingular S such that $S^{-1}\mathcal{F}S = \{W_A, S^{-1}A_1S, S^{-1}A_2S, \ldots\}$ is an upper triangular family and W_A is the Weyr canonical form of A. There need not be a nonsingular S such that $S^{-1}\mathcal{F}S = \{J_A, S^{-1}A_1S, S^{-1}A_2S, \ldots\}$ is an upper triangular family and J_A is the Jordan canonical form of A.

Examples:

1. The Weyr characteristic of the Jordan matrix

$$J = J_3(0) \oplus J_3(0) \oplus J_2(0) \oplus J_2(0) \oplus J_2(0) \oplus J_1(0)$$

associated with the eigenvalue zero is $w(J, 0) = (6, 5, 2)$. The Weyr canonical form of J is

$$W_J = \begin{bmatrix} 0_6 & G_{6,5} & \\ & 0_5 & G_{5,2} \\ & & 0_2 \end{bmatrix}$$

2. Let $J = J_2(\lambda) \oplus J_2(\lambda)$.
    (a) $W_J = \begin{bmatrix} \lambda I_2 & I_2 \\ 0_2 & \lambda I_2 \end{bmatrix}$.

    (b) A commutes with J if and only if $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$ in which each block A_{11}, A_{12}, A_{21}, $A_{22} \in F^{2\times 2}$ is upper triangular Toeplitz. For example, $A = \begin{bmatrix} 1 & 2 & 3 & 4 \\ 0 & 1 & 0 & 3 \\ -1 & 5 & 7 & -2 \\ 0 & -1 & 0 & 7 \end{bmatrix}$ commutes with $J = J_2(\lambda) \oplus J_2(\lambda)$.

    (c) A commutes with W_J if and only if $A = \begin{bmatrix} B_1 & B_2 \\ 0 & B_1 \end{bmatrix}$ with $B_1, B_2 \in F^{2\times 2}$; observe that A is block upper triangular. For example, $A = \begin{bmatrix} 1 & 2 & 3 & 4 \\ -3 & 0 & -1 & -2 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & -3 & 0 \end{bmatrix}$ commutes with $W_J = \begin{bmatrix} \lambda I_2 & I_2 \\ 0_2 & \lambda I_2 \end{bmatrix}$.

3. Let $J = J_2(0) \oplus J_2(0)$ and $A = \begin{bmatrix} 0 & I_2 \\ J_2(0) & 0 \end{bmatrix}$. Then $\mathcal{F} = \{J, A\}$ is a commuting family, but there is no simultaneous similarity of J and A that leaves J in Jordan canonical form and puts A into block upper triangular form; for details, see [HJ13, Problem 7 in Sect. 3.4].

6.5 Rational Canonical Form: Elementary Divisors

The elementary divisors rational canonical form is closely related to the Jordan canonical form (see Fact 7 below). A rational canonical form (either the elementary divisors or the invariant factors version, cf. Section 6.7) is used when it is desirable to stay within a field that is not algebraically closed, such as the rational numbers.

Definitions:

Let F be a field.

For a monic polynomial $p(x) = x^n + c_{n-1}x^{n-1} + \cdots + c_2x^2 + c_1x + c_0 \in F[x]$ (with $n \geq 1$), the **companion matrix** of $p(x)$ is the $n \times n$ matrix $C(p) = \begin{bmatrix} 0 & 0 & \cdots & -c_0 \\ 1 & 0 & \cdots & -c_1 \\ \vdots & \ddots & & \vdots \\ 0 & \cdots & 1 & -c_{n-1} \end{bmatrix}$.

An **elementary divisors rational canonical form matrix (ED-RCF matrix)** (over F) is a block diagonal matrix of the form $C(h_1^{m_1}) \oplus \cdots \oplus C(h_t^{m_t})$ where each $h_i(x)$ is a monic polynomial that is irreducible over F.

The **elementary divisors** of the ED-RCF matrix $C(h_1^{m_1}) \oplus \cdots \oplus C(h_t^{m_t})$ are the polynomials $h_i(x)^{m_i}$, $i = 1, \ldots t$.

An **elementary divisors rational canonical form** of matrix $A \in F^{n \times n}$, denoted $\mathrm{RCF}_{ED}(A)$, is an ED-RCF matrix that is similar to A. It is conventional to group the companion matrices associated with powers of the same irreducible polynomial together, and within such a group to order the blocks in size order.

The **elementary divisors** of A are the elementary divisors of $\mathrm{RCF}_{ED}(A)$.

Let V be a finite dimensional vector space over F, and let T be a linear operator on V.

An **ED-RCF basis** for T is an ordered basis $\mathcal{B}$ of V, with respect to which the matrix ${}_{\mathcal{B}}[T]_{\mathcal{B}}$ of T is an ED-RCF matrix. In this case, ${}_{\mathcal{B}}[T]_{\mathcal{B}}$ is an elementary divisors rational canonical form of T, denoted $\mathrm{RCF}_{ED}(T)$, and the **elementary divisors** of T are the elementary divisors of $\mathrm{RCF}_{ED}(T) ={}_{\mathcal{B}} [T]_{\mathcal{B}}$.

Let $q(x)$ be a monic polynomial over F.

A **primary decomposition** of a nonconstant monic polynomial $q(x)$ over F is a factorization $q(x) = (h_1(x))^{m_1} \cdots (h_r(x))^{m_r}$, where the $h_i(x), i = 1, \ldots, r$ are distinct monic irreducible polynomials over F.

The factors $(h_i(x))^{m_i}$ in a primary decomposition of $q(x)$ are the **primary factors** of $q(x)$.

Facts:

Facts requiring proof for which no specific reference is given can be found in [HK71, Chap. 7] or [DF04, Chap. 12].

1. The characteristic and minimal polynomials of the companion matrix $C(p)$ are both equal to $p(x)$.
2. Whether or not a matrix is an ED-RCF matrix depends on polynomial irreducibility, which depends on the field. See Example 1 below.
3. Every matrix $A \in F^{n \times n}$ is similar to an ED-RCF matrix, $\mathrm{RCF}_{ED}(A)$, and $\mathrm{RCF}_{ED}(A)$

is unique up to permutation of the companion matrix blocks on the diagonal. In particular, the elementary divisors of A are uniquely determined by A.

4. $A, B \in F^{n\times n}$ are similar if and only if they have the same elementary divisors.
5. (See Fact 6.2.3) For $A \in F^{n\times n}$, the elementary divisors and, hence, $\text{RCF}_{ED}(A)$ can be found from the irreducible factors $h_i(x)$ of the characteristic polynomial of A and the ranks of powers of $h_i(A)$. Specifically, the number of times $h_i(x)^k$ appears as an elementary divisor of A is
$$\frac{1}{\deg h_i(x)}(\text{rank}(h_i(A))^{k-1} + \text{rank}(h_i(A))^{k+1} - 2\,\text{rank}(h_i(A))^k).$$
6. If $A \in F^{n\times n}$ has n eigenvalues in F, then the elementary divisors of A are the polynomials $(x-\lambda)^k$, where the $J_k(\lambda)$ are the Jordan blocks of J_A.
7. There is a natural association between the diagonal blocks in the elementary divisors rational canonical form of A and the Jordan canonical form of A in $\hat{F}^{n\times n}$, where $\hat{F}$ is the algebraic closure of F. Let $h(x)^m$ be an elementary divisor of A, and factor $h(x)$ into monic linear factors over $\hat{F}$, $h(x) = (x-\lambda_1)\cdots(x-\lambda_t)$. If the roots of $h(x)$ are distinct (e.g., if the characteristic of F is 0 or F is a finite field), then the ED-RCF diagonal block $C(h^m)$ is associated with the Jordan blocks $J_m(\lambda_i), i = 1,\dots,t$. If the characteristic of F is p and $h(x)$ has repeated roots, then all roots have the same multiplicity p^k (for some positive integer k) and the ED-RCF diagonal block $C(h^m)$ is associated with the Jordan blocks $J_{p^k m}(\lambda_i), i = 1,\dots,t$.
8. [HK71, Sect. 4.5] Every monic polynomial $q(x)$ over F has a primary decomposition. The primary decomposition is unique up to the order of the monic irreducible polynomials, i.e., the multiset of primary factors of $q(x)$ is unique.
9. [HK71, Sect. 6.8] Let $q(x) \in F[x]$, let $h_i(x)^{m_i}, i = 1,\dots,r$ be the primary factors, and define $f_i(x) = \frac{q(x)}{h_i(x)^{m_i}}$. Then there exist polynomials $g_i(x)$ such that $f_1(x)g_1(x) + \cdots + f_r(x)g_r(x) = 1$.

Let $A \in F^{n\times n}$ and let $q_A(x) = (h_1(x))^{m_1}\cdots(h_r(x))^{m_r}$ be a primary decomposition of its minimal polynomial.

10. Every primary factor $h_i(x)^{m_i}$ of $q_A(x)$ is an elementary divisor of A.
11. Every elementary divisor of A is of the form $(h_i(x))^m$ with $m \leq m_i$ for some $i \in \{1,\dots,r\}$.
12. [HK71, Chap. 6.8] *Primary Decomposition Theorem*
    (a) $F^n = \ker(h_1(A)^{m_1}) \oplus \cdots \oplus \ker(h_r(A)^{m_r})$.
    (b) Let f_i and g_i be as defined in Fact 9. Then for $i = 1,\dots,r$, $E_i = f_i(A)g_i(A)$ is the projection onto $\ker(h_i(A)^{m_i})$ along $\ker(h_1(A)^{m_1}) \oplus \cdots \oplus \ker(h_{i-1}(A)^{m_{i-1}}) \oplus \ker(h_{i+1}(A)^{m_{i+1}}) \oplus \cdots \oplus \ker(h_r(A)^{m_r})$.
    (c) The $E_i = f_i(A)g_i(A)$ are mutually orthogonal idempotents (i.e., $E_i^2 = E_i$ and $E_iE_j = 0$ if $i \neq j$) and $I = E_1 + \cdots + E_r$.
13. [HK71, Chap. 6.7] If $A \in F^{n\times n}$ is diagonalizable, then $A = \mu_1 E_1 + \cdots + \mu_r E_R$ where the E_i are the projections defined in Fact 12 with primary factors $h_i(x)^{m_i} = (x-\mu_i)$ of $q_A(x)$.

Let V be an n-dimensional vector space over F, and let T be a linear operator on V.

14. Facts 3, 5 to 7, and 10 to 13 remain true when matrix A is replaced by linear operator T; in particular, $\text{RCF}_{ED}(T)$ exists and is independent (up to permutation of the companion matrix diagonal blocks) of the ordered basis of V used to compute it, and the elementary divisors of T are independent of basis.
15. If $\hat{T}$ denotes T restricted to $\ker(h_i(T)^{m_i})$, then the minimal polynomial of $\hat{T}$ is $h_i(T)^{m_i}$.

Examples:

1. Let $A = [-1] \oplus [-1] \oplus \begin{bmatrix} 0 & 0 & -1 \\ 1 & 0 & -3 \\ 0 & 1 & -3 \end{bmatrix} \oplus \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix} \oplus \begin{bmatrix} 0 & 0 & 0 & -4 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 4 \\ 0 & 0 & 1 & 0 \end{bmatrix}$. Over $\mathbb{Q}$, A is an ED-RCF matrix and its elementary divisors are $x+1, x+1, (x+1)^3, x^2-2, (x^2-2)^2$. A is not an ED-RCF matrix over $\mathbb{C}$ because x^2-2 is not irreducible over $\mathbb{C}$.

   JCF(A)=$[-1] \oplus [-1] \oplus \begin{bmatrix} -1 & 1 & 0 \\ 0 & -1 & 1 \\ 0 & 0 & -1 \end{bmatrix} \oplus [\sqrt{2}] \oplus [-\sqrt{2}] \oplus \begin{bmatrix} \sqrt{2} & 1 \\ 0 & \sqrt{2} \end{bmatrix} \oplus \begin{bmatrix} -\sqrt{2} & 1 \\ 0 & -\sqrt{2} \end{bmatrix}$, where the order of the Jordan blocks has been chosen to emphasize the connection to $\mathrm{RCF}_{ED}(A) = A$.

2. Let $A = \begin{bmatrix} -2 & 2 & -2 & 1 & 1 \\ 6 & -2 & 2 & -2 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ -12 & 7 & -8 & 5 & 4 \\ 0 & 0 & -1 & 0 & 2 \end{bmatrix} \in \mathbb{Q}^{5\times 5}$. We use Fact 5 to determine the elementary divisors rational canonical form of A. The following computations can be performed easily over $\mathbb{Q}$ in a computer algebra system such as Maple, Mathematica, or Sage (see Chapters 89, 90, 91). $p_A(x) = x^5 - 3x^4 + x^3 + 5x^2 - 6x + 2 = (x-1)^3\left(x^2-2\right)$. Table 6.2 gives the of ranks $h_i(A)^k$ where $h_i(x)$ is shown in the left column.

   TABLE 6.2 rank($h(A)^k$)

$k =$	1	2	3
$h_1(x) = x - 1$	3	2	2
$h_2(x) = x^2 - 2$	3	3	3

   $h(x) = x - 1$ Number of times $x-1$ appears as an elementary divisor is $5 + 2 - 2\cdot 3 = 1$.
   Number of $(x-1)^2$ appears as an elementary divisor is $3 + 2 - 2 \cdot 2 = 1$.

   $h(x) = x^2 - 2$ Number of times x^2-2 appears as an elementary divisor is $(5+3-2\cdot 3)/2 = 1$.

   Thus, $\mathrm{RCF}_{ED}(A) = C(x-1) \oplus C((x-1)^2) \oplus C(x^2-2) = [1] \oplus \begin{bmatrix} 0 & -1 \\ 1 & 2 \end{bmatrix} \oplus \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}$.

3. We find the projections $E_i, i = 1, 2$ in Fact 12 for A in the previous example. From the elementary divisors of A, $q_A(x) = (x-1)^2(x^2-2)$. Let $h_1(x) = (x-1)^2, h_2(x) = x^2 - 2$. Then $f_1(x) = x^2 - 2, f_2(x) = (x-1)^2$. *Note:* normally the $f_i(x)$ will not be primary factors; this happens here because there are only two primary factors. If we choose $g_1(x) = -(2x-1), g_2(x) = 2x + 3$, then $1 = f_1(x)g_1(x) + f_2(x)g_2(x)$ (g_1, g_2 can be found by the Euclidean algorithm). Then

   $$E_1 = f_1(A)g_1(A) = \begin{bmatrix} -2 & 1 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ -6 & 3 & -2 & 3 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad E_2 = f_2(A)g_2(A) = \begin{bmatrix} 3 & -1 & 1 & -1 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 6 & -3 & 2 & -2 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

   and it is easy to verify that $E_1^2 = E_1, E_2^2 = E_2, E_1E_2 = E_2E_1 = 0$, and $E_1 + E_2 = I$.

6.6 Smith Normal Form on $F[x]^{n\times n}$

For a matrix $A \in F^{n\times n}$, the Smith normal form of $xI_n - A$ is an important tool for the computation of the invariant factors rational canonical form of A discussed in Section 6.7. In this section, Smith normal form is discussed only for matrices in $F[x]^{n\times n}$, and the emphasis is on finding the Smith normal form of $xI_n - A$, where $A \in F^{n\times n}$. Smith normal form is used more generally for matrices over principal ideal domains (see Section 32.2); it is not used extensively as a canonical form within $F^{n\times n}$, since the Smith normal form of a matrix $A \in F^{n\times n}$ of rank k is $I_k \oplus 0_{n-k}$.

Definitions:

Let F be a field. For $M \in F[x]^{n\times n}$, the following operations are the **elementary row and column operations** on M:

(a) Interchange rows i, j, denoted $R_i \leftrightarrow R_j$ (analogous column operation denoted $C_i \leftrightarrow C_j$).

(b) Add a $p(x)$ multiple of row j to row i, denoted $R_i + p(x)R_j \rightarrow R_i$ (analogous column operation denoted $C_i + p(x)C_j \rightarrow C_i$).

(c) Multiply row i by a nonzero element b of F, denoted $bR_i \rightarrow R_i$ (analogous column operation denoted $bC_i \rightarrow C_i$).

A **Smith normal matrix** in $F[x]^{n\times n}$ is a diagonal matrix

$$D = \operatorname{diag}(1, \ldots, 1, a_1(x), \ldots, a_s(x), 0, \ldots, 0),$$

where the $a_i(x)$ are monic nonconstant polynomials such that $a_i(x)$ divides $a_{i+1}(x)$, $i = 1, \ldots, s-1$.

The **Smith normal form** of $M \in F[x]^{n\times n}$ is the Smith normal matrix obtained from M by elementary row and column operations.

For $A \in F^{n\times n}$, the monic nonconstant polynomials of the Smith normal form of $xI_n - A$ are the **Smith invariant factors** of A.

Facts:

Facts requiring proof for which no specific reference is given can be found in [HK71, Chap. 7] or [DF04, Chap. 12].

1. Let $M \in F[x]^{n\times n}$. Then M has a unique Smith normal form.
2. Let $A \in F^{n\times n}$. There are no zeros on the diagonal of the Smith normal form of $xI_n - A$.
3. (*Division Property*) If $a(x), b(x) \in F[x]$ and $b(x) \neq 0$, then there exist polynomials $q(x), r(x)$ such that $a(x) = q(x)b(x) + r(x)$ and $r(x) = 0$ or $\deg r(x) < \deg b(x)$.
4. The Smith normal form of $M = xI - A$ and, thus, the Smith invariant factors of A can be computed as follows:
    - For $k = 1, \ldots, n-1$
        - Use elementary row and column operations and the division property of $F[x]$ to place the greatest common divisor of the entries of $M[\{k, \ldots, n\}]$ in the kth diagonal position.
        - Use elementary row and column operations to create zeros in all nondiagonal positions in row k and column k.
    - Make the nth diagonal entry monic by multiplying the last column by a nonzero element of F.

    This process is illustrated in Example 1 next.

Examples:

1. Let $A = \begin{bmatrix} 1 & 1 & 1 & -1 \\ 0 & 3 & 2 & -2 \\ 2 & 0 & 4 & -2 \\ 4 & 0 & 6 & -3 \end{bmatrix}$. We use the method in Fact 4 to find the Smith normal form of $M = xI - A$ and Smith invariant factors of A.

   - $k = 1$: Use the row and column operations on M (in the order shown):
     $R_1 \leftrightarrow R_3$, $-\frac{1}{2}R_1 \to R_1$, $R_3 + (1-x)R_1 \to R_3$, $R_4 + 4R_1 \to R_4$,
     $C_3 + (-2 + \frac{x}{2})C_1 \to C_3$, $C_4 + C_1 \to C_4$
     to obtain $M_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & x-3 & -2 & 2 \\ 0 & -1 & \frac{x^2}{2} - \frac{5x}{2} + 1 & x \\ 0 & 0 & 2-2x & x-1 \end{bmatrix}$.
   - $k = 2$: Use the row and column operations on M_1 (in the order shown):
     $R_3 \leftrightarrow R_2$, $-1R_2 \to R_2$, $R_3 + (3-x)R_2 \to R_3$,
     $C_3 + (1 - \frac{5x}{2} + \frac{x^2}{2})C_2 \to C_3$, $C_4 + xC_2 \to C_4$
     to obtain $M_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \frac{x^3}{2} - 4x^2 + \frac{17x}{2} - 5 & x^2 - 3x + 2 \\ 0 & 0 & 2-2x & x-1 \end{bmatrix}$.
   - $k = 3$ (and final step): Use the row and column operations on M_2 (in the order shown):
     $R_3 \leftrightarrow R_4$, $-\frac{1}{2}R_3 \to R_3$, $R_4 + \frac{-1}{2}(x-2)(x-5)R_3 \to R_4$,
     $C_4 + \frac{1}{2}C_3 \to C_4$, $4C_4 \to C_4$
     to obtain the Smith normal form of M, $M_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & x-1 & 0 \\ 0 & 0 & 0 & x^3 - 4x^2 + 5x - 2 \end{bmatrix}$.

   The Smith invariant factors of A are $x - 1$, $x^3 - 4x^2 + 5x - 2$.

6.7 Rational Canonical Form: Invariant Factors

Like the elementary divisors version, the invariant factors rational canonical form does not require the field to be algebraically closed. It has two other advantages: This canonical form is unique (not just unique up to permutation), and (unlike elementary divisors rational canonical form) whether a matrix is in invariant factors rational canonical form is independent of the field (see Fact 2 next).

Definitions:

Let F be a field. An **invariant factors rational canonical form matrix (IF-RCF matrix)** is a block diagonal matrix of the form $C(a_1)\oplus\cdots\oplus C(a_s)$, where $a_i(x)$ divides $a_{i+1}(x)$ for $i = 1, \ldots, s-1$.

The **invariant factors** of the IF-RCF matrix $C(a_1)\oplus\cdots\oplus C(a_s)$ are the polynomials $a_i(x), i = 1, \ldots s$.

The **invariant factors rational canonical form** of matrix $A \in F^{n\times n}$, denoted $\text{RCF}_{IF}(A)$, is the IF-RCF matrix that is similar to A.

The **invariant factors** of A are the invariant factors of $\text{RCF}_{IF}(A)$.

Let V be a finite dimensional vector space over F and let T be a linear operator on V.

An **IF-RCF basis** for T is an ordered basis $\mathcal{B}$ of V, with respect to which the matrix ${}_{\mathcal{B}}[T]_{\mathcal{B}}$ of T is an IF-RCF matrix. In this case, ${}_{\mathcal{B}}[T]_{\mathcal{B}}$ is the **invariant factors rational canonical form of** T, denoted $\mathrm{RCF}_{IF}(T)$, and the **invariant factors** of T are the invariant factors of $\mathrm{RCF}_{IF}(T) ={}_{\mathcal{B}} [T]_{\mathcal{B}}$.

Facts:

Facts requiring proof for which no specific reference is given can be found in [HK71, Chap. 7] or [DF04, Chap. 12].

Notation: $A \in F^{n\times n}$.

1. Every square matrix A is similar to a unique IF-RCF matrix, $\mathrm{RCF}_{IF}(A)$.
2. $\mathrm{RCF}_{IF}(A)$ is independent of field. That is, if F is a subfield of a larger field K and $A \in F^{n\times n}$, then viewing $A \in K^{n\times n}$ instead of $F^{n\times n}$ does not change $\mathrm{RCF}_{IF}(A)$.
3. Let $B \in F^{n\times n}$. Then A, B are similar if and only if $\mathrm{RCF}_{IF}(A) = \mathrm{RCF}_{IF}(B)$.
4. The characteristic polynomial is the product of the invariant factors of A, i.e., $p_A(x) = a_1(x)\cdots a_s(x)$.
5. The minimal polynomial of A is the invariant factor of highest degree, i.e., $q_A(x) = a_s(x)$.
6. The elementary divisors of $A \in F^{n\times n}$ are the primary factors (over F) of the invariant factors of A.
7. The Smith invariant factors of A are the invariant factors of A.
8. [DF04, Chap. 12.2] $\mathrm{RCF}_{IF}(A)$ and a nonsingular matrix $S \in F^{n\times n}$ such that $S^{-1}AS = \mathrm{RCF}_{IF}(A)$ can be computed by Algorithm 2.

Algorithm 2: Rational Canonical Form (invariant factors)

```
1. Compute the Smith normal form $D$ of $M = xI - A$ as in Fact 6.6.4, keeping
   track of the elementary row operations, in the order performed (column
   operations need not be recorded).
2. The invariant factors are the nonconstant diagonal elements $a_1(x), \dots, a_s(x)$
   of $D$.
3. Let $d_1, \dots, d_s$ denote the degrees of $a_1(x), \dots, a_s(x)$.
4. Let $G = I$.
5. FOR $k = 1, \dots,$ number of row operations performed in Step 1
   (a) If the $k$th row operation is $R_i \leftrightarrow R_j$, then perform column operation
       $C_j \leftrightarrow C_i$ on $G$.
   (b) If the $k$th row operation is $R_i + p(x)R_j \to R_i$, then perform column
       operation $C_j - p(A)C_i \to C_j$ on $G$ (note index reversal).
   (c) If the $k$th row operation is $bR_i \to R_i$, then perform column operation
       $\frac{1}{b}C_i \to C_i$ on $G$.
6. $G$ will have 0s in the first $n - s$ columns; denote the remaining columns of $G$
   by $\mathbf{g}_1, \dots, \mathbf{g}_s$.
7. Initially $S$ has no columns.
8. FOR $k = 1, \dots, s$
   (a) Insert $\mathbf{g}_k$ as the next column of $S$ (working left to right).
   (b) FOR $i = 1, \dots, d_k - 1$.
       Insert $A$ times the last column inserted as the next column of $S$.
9. $\mathrm{RCF}_{IF}(A) = S^{-1}AS$.
```

9. Let V be an n-dimensional vector space over F, and let T be a linear operator on V. Facts 1, 2, and 4 to 6 remain true when matrix A is replaced by linear operator T; in particular, $\mathrm{RCF}_{IF}(T)$ exists and is unique (independent of the ordered basis of V used to compute it).

Examples:

1. We can use the elementary divisors already computed to find the invariant factors and IF-RCF of A in Example 6.5.2. The elementary divisors of A are $x-1, (x-1)^2, x^2-2$. We combine these, working down from the highest power of each irreducible polynomial. $a_2(x) = (x-1)^2(x^2-2) = x^4 - 2x^3 - x^2 + 4x - 2, a_1(x) = x - 1$. Then
$$\mathrm{RCF}_{IF}(A) = C(x-1) \oplus C(x^4 - 2x^3 - x^2 + 4x - 2) = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 2 \\ 0 & 1 & 0 & 0 & -4 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 2 \end{bmatrix}.$$
2. By Fact 7, for the matrix A in Example 6.6.1, $\mathrm{RCF}_{IF}(A) = C(x-1) \oplus C(x^3 - 4x^2 + 5x - 2)$.
3. We can use Algorithm 2 to find a matrix S such that $\mathrm{RCF}_{IF}(A) = S^{-1}AS$ for the matrix A in Example 6.6.1.

   - $k = 1$: Starting with $G = I_4$, perform the column operations (in the order shown):
     $C_1 \leftrightarrow C_3$, $-2C_1 \to C_1$, $C_1 - (I_4 - A)C_3 \to C_1$, $C_1 - 4C_4 \to C_1$,
     to obtain $G = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$.
   - $k = 2$: Use column operations on G (in the order shown):
     $C_3 \leftrightarrow C_2$, $-1C_2 \to C_2$, $C_2 - (3I_4 - A)C_3 \to C_2$,
     to obtain $G = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$.
   - $k = 3$ (and final step of Fact 6.6.4):
     Use column operations on G (in the order shown):
     $C_3 \leftrightarrow C_4$, $-2C_3 \to C_3$, $C_3 + \frac{1}{2}(A - 2I_4)(A - 5I_4)C_4 \to C_3$,
     to obtain $G = [\mathbf{g}_1, \mathbf{g}_2, \mathbf{g}_3, \mathbf{g}_4] = \begin{bmatrix} 0 & 0 & -\frac{3}{2} & 0 \\ 0 & 0 & -1 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$.

$$\text{Then } S = [\mathbf{g}_3, \mathbf{g}_4, A\mathbf{g}_4, A^2\mathbf{g}_4] = \begin{bmatrix} -\frac{3}{2} & 0 & 1 & 4 \\ -1 & 1 & 3 & 9 \\ 1 & 0 & 0 & 2 \\ 0 & 0 & 0 & 4 \end{bmatrix} \text{ and } \mathrm{RCF}_{IF}(A) = S^{-1}AS = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 \\ 0 & 1 & 0 & -5 \\ 0 & 0 & 1 & 4 \end{bmatrix}.$$

We discuss canonical forms for several equivalence relations other than similarity. See Chapter 6 for information about canonical forms for the equivalence relation of similarity, and see the introduction to Chapter 6 for a discussion of the concept of a canonical form for an equivalence relation on $\mathbb{C}^{m\times n}$.

7.1 Equivalence and Unitary Equivalence

Definitions:

Matrices $A, B \in \mathbb{C}^{m\times n}$ are **equivalent** if there are nonsingular matrices $S \in \mathbb{C}^{m\times m}$ and $T \in \mathbb{C}^{n\times n}$ such that $A = SBT$; they are **unitarily equivalent** if there are unitary matrices $V \in \mathbb{C}^{m\times m}$ and $W \in \mathbb{C}^{n\times n}$ such that $A = VBW$.

Facts:

See [HJ13, Chaps. 0 and 2] for the following facts.

1. Equivalence and unitary equivalence of matrices are equivalence relations.
2. *Canonical form under equivalence:* Each $A \in \mathbb{C}^{m\times n}$ is equivalent to an $m \times n$ block matrix of the form $\begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix}$, in which I_r is the $r \times r$ identity matrix and $r = \operatorname{rank} A$.
3. $A, B \in \mathbb{C}^{m\times n}$ are equivalent if and only if $\operatorname{rank} A = \operatorname{rank} B$.
4. *Canonical form under unitary equivalence:* Each $A \in \mathbb{C}^{m\times n}$ is unitarily equivalent to an $m\times n$ block matrix of the form $\begin{bmatrix} \Sigma_r & 0 \\ 0 & 0 \end{bmatrix}$, in which $r = \operatorname{rank} A$, $\Sigma_r = \operatorname{diag}(\sigma_1, \dots, \sigma_r)$ is a nonnegative diagonal matrix, and $\sigma_1 \geq \cdots \geq \sigma_r > 0$. The scalars $\sigma_1, \dots, \sigma_r$ are the positive singular values of A; they are uniquely determined as the nonincreasingly ordered positive square roots of the positive eigenvalues of A^*A (equivalently, of AA^*). See Chapters 5 and 24 for more information about singular values.
5. $A, B \in \mathbb{C}^{m\times n}$ are unitarily equivalent if and only if they have the same positive singular values.

Examples:

1. The $m \times n$ zero matrix is equivalent only to itself; it is the only rank-zero matrix.
2. The rank-one matrix $\begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix}$ is equivalent to $\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$; it is unitarily equivalent to $\begin{bmatrix} \sqrt{10} & 0 \\ 0 & 0 \end{bmatrix}$.

7.2 *Congruence (Conjunctivity) and Unitary Similarity

Definitions:

Matrices $A, B \in \mathbb{C}^{n\times n}$ are ***congruent** (**conjunctive**) if there is a nonsingular $S \in \mathbb{C}^{n\times n}$ such that $A = SBS^*$; they are **unitarily *congruent** (**unitarily similar**) if there is a unitary $U \in \mathbb{C}^{n\times n}$ such that $A = UBU^*$.

A matrix $A \in \mathbb{C}^{n\times n}$ is **normal** if $AA^* = A^*A$; it is **squared normal** if A^2 is normal; and it is **cubed normal** if A^3 is normal.

A matrix $A \in \mathbb{C}^{n\times n}$ is **quasitriangular** if it is block upper triangular and its diagonal blocks are either 1×1 or 2×2.

If $A \in \mathbb{C}^{n\times n}$ is nonsingular, then its ***cosquare** is $A^{-*}A$, in which $A^{-*} = (A^{-1})^* = (A^*)^{-1}$.

A matrix classification problem is **unitarily wild** if it contains the problem of classifying arbitrary square complex matrices under unitary similarity.

The upper triangular $k \times k$ Jordan block with eigenvalue μ is denoted by $J_k(\mu)$; see Section 6.2.

For each $k = 1, 2, \ldots$ define the $k \times k$ symmetric Hankel matrix

$$\Delta_k = \begin{bmatrix} 0 & & & 1 \\ & & \iddots & i \\ & 1 & \iddots & \\ 1 & i & & 0 \end{bmatrix} \in \mathbb{C}^{k\times k}.$$

The smallest blocks of this form are $\Delta_1 = [1]$ and $\Delta_2 = \begin{bmatrix} 0 & 1 \\ 1 & i \end{bmatrix}$.

For each $k = 1, 2, \ldots$ and $\mu \in \mathbb{C}$ define the $2k \times 2k$ block matrix

$$H_{2k}(\mu) = \begin{bmatrix} 0 & I_k \\ J_k(\mu) & 0 \end{bmatrix} \in \mathbb{C}^{2k\times 2k}.$$

The smallest block of this form is $H_2(\mu) = \begin{bmatrix} 0 & 1 \\ \mu & 0 \end{bmatrix}$.

Facts:

Facts for which no specific reference is given can be found in [HJ13, Chaps. 2 and 4]. For more information about *congruence, see Chapters 9 and 13; for more information about unitary similarity, see Chapter 8.

1. *Congruence is an equivalence relation.
2. Unitary *congruence is the same as unitary similarity.
3. Two Hermitian matrices of the same size are *congruent if and only if they have the same inertia (see Section 9.3), if and only if they have the same numbers of eigenvalues on each of the open rays $(0, \infty)$ and $(-\infty, 0)$.
4. Two normal matrices of the same size are *congruent if and only if they have the same numbers of eigenvalues on each of the open rays $\{re^{i\theta} : r > 0\}, \theta \in [0, 2\pi)$.

5. *Sylvester's Law of Inertia:* Each Hermitian matrix is *congruent to a unique matrix of the form $I_r \oplus (-I_s) \oplus 0_t$.
6. **Congruence canonical form:* Each $A \in \mathbb{C}^{n\times n}$ is *congruent to a direct sum, uniquely determined up to permutation of direct summands, of matrices of the following three types:

   Type 0: $J_k(0)$, $k = 1, 2, \ldots$;

   Type I: $\lambda\Delta_k$, $k = 1, 2, \ldots$, in which $|\lambda| = 1$; and

   Type II: $H_{2k}(\mu)$, $k = 1, 2, \ldots$, in which $|\mu| > 1$.
7. Algorithms to determine the *congruence canonical form of a given complex matrix are in [HS06].
8. If nonsingular complex matrices of the same size are *congruent, then their *cosquares are similar. The converse implication is false; see Example 1.
9. *Schur's triangularization theorem:* Each $A \in \mathbb{C}^{n\times n}$ is unitarily similar to an upper triangular matrix T. The main diagonal entries of T are the eigenvalues of A, which may be chosen to appear in any desired order.
10. *Real Schur form:* Each real $A \in \mathbb{R}^{n\times n}$ is real orthogonally similar to a real quasitriangular matrix, each of whose 2×2 diagonal blocks has a conjugate pair of non-real eigenvalues.
11. If $A \in \mathbb{C}^{n\times n}$ and $A\bar{A} = \bar{A}A$, then A is real orthogonally similar to a quasitriangular matrix; see [HJ13, Corollary 2.3.7] for details about the structure of its diagonal blocks.
12. Each normal $A \in \mathbb{C}^{n\times n}$ is unitarily similar to a diagonal matrix that is uniquely determined up to permutation of its diagonal entries, which are the eigenvalues of A.
13. Each real normal $A \in \mathbb{R}^{n\times n}$ is real orthogonally similar to a direct sum, uniquely determined up to permutation of direct summands, of real blocks of the form $[\lambda]$ or $B(a,b) = \begin{bmatrix} a & b \\ -b & a \end{bmatrix}$, in which λ, a, b are real and $b > 0$. Each block $[\lambda]$ corresponds to a real eigenvalue λ of A; each block $B(a,b)$ corresponds to a conjugate pair of non-real eigenvalues $a \pm ib$ of A.
14. If $A \in \mathbb{C}^{n\times n}$ is normal and either $A\bar{A} = \bar{A}A$ or $AA^T = A^TA$, then A is real orthogonally similar to a direct sum of a zero block and nonzero scalar multiples of blocks of four types: $[1]$, $H_2(-1)$, $B(a,b) = \begin{bmatrix} a & b \\ -b & a \end{bmatrix}$, and $C = \begin{bmatrix} 1 & i \\ -i & 1 \end{bmatrix}$, in which $a, b \in \mathbb{C}$, $a \neq 0 \neq b$, and $a^2 + b^2 = 1$. This direct sum is uniquely determined up to permutation of its blocks and replacement of any block $B(a,b)$ by $B(a,b)^T$; see [GH09, Sect. 3]. Each of the matrices $H_2(-1)$, $B(a,b)$, and C is real orthogonally similar to its transpose.
15. Each squared normal $A \in \mathbb{C}^{n\times n}$ is unitarily similar to a direct sum, uniquely determined up to permutation of direct summands, of blocks of the form $[\lambda]$ or $\tau H_2(\mu)$, in which $\tau \in \mathbb{R}$, $\lambda, \mu \in \mathbb{C}$, $\tau > 0$, and $|\mu| < 1$. Alternatively, the 2×2 blocks may be taken to have the form $\begin{bmatrix} \nu & r \\ 0 & -\nu \end{bmatrix}$, in which r is real and positive, and either $\operatorname{Re}\nu > 0$ or $\operatorname{Re}\nu = 0$ and $\operatorname{Im}\nu \geq 0$.
16. [HS09, Sect. 8.8] The problem of classifying cubed normal matrices under unitary similarity is unitarily wild, so it may be considered to be hopeless (see [Ser98, Sect. 2.3]).
17. [HS08] A canonical form under *congruence is known for matrices over an algebraically closed field and over $\mathbb{P}$-quaternions ($\mathbb{P}$ is a real closed field) with respect to any nonidentity involution. It is also known for matrices over a field $\mathbb{F}$ of characteristic different from 2 with involution (possibly the identity) up to classification of Hermitian forms over finite extensions of $\mathbb{F}$.

18. [Lit53] *Littlewood's algorithm:* Littlewood constructed an algorithm that transforms each square complex matrix A to a matrix A_{can} that is unitarily similar to A and is such that A is unitarily similar to B if and only if $A_{\text{can}} = B_{\text{can}}$. The matrix A_{can} is called *Littlewood's canonical form* of A under unitary similarity. See [HJ13, Theorem 3.4.3.1] for a related (but not canonical) form to which A is unitarily similar; it incorporates the block structure of the Weyr canonical form of A.
19. [Ser98] Littlewood's algorithm has been extended to matrices of systems $(U_1, \ldots, U_t; \mathcal{A}_1, \ldots, \mathcal{A}_r)$ in which each U_i is a complex inner product space and each $\mathcal{A}_i$ is a linear operator between any two of the spaces. Each system decomposes into a direct sum of indecomposable systems that is unique up to isomorphism of summands; the set of dimensions $(\dim U_1, \ldots, \dim U_t)$ of indecomposable systems has been described.

Examples:

1. The *cosquares of the matrices $A = [1]$ and $B = [-1]$ are the same, but A and B are not *congruent.
2. The *congruence canonical form of a normal matrix A is the direct sum of a zero matrix and a diagonal unitary matrix D. If $\operatorname{rank} A = k$ and the nonzero eigenvalues of A are $r_1 e^{i\theta_1}, \ldots, r_k e^{i\theta_k}$ (each $r_j > 0$ and each $\theta_j \in [0, 2\pi)$), then the diagonal entries of D are $e^{i\theta_1}, \ldots, e^{i\theta_k}$.
3. Fact 15 ensures that if $A \in \mathbb{C}^{n\times n}$ and A^2 is Hermitian, then A is unitarily similar to a direct sum of matrices of the form $[\lambda]$, $[i\lambda]$, or $\tau H_2(\mu)$, in which λ, μ, τ are real, $\tau > 0$, and $-1 < \mu < 1$.
4. It follows from the preceding example that if $A \in \mathbb{C}^{n\times n}$ and $A^2 = 0$, then A is unitarily similar to a direct sum of matrices of the form $[0]$ or $\tau H_2(0) = \tau J_2(0)$, in which τ is real and positive.
5. If $A \in \mathbb{C}^{n\times n}$ is symmetric and normal, Fact 14 ensures that it is real orthogonally similar to a diagonal matrix; that diagonal matrix is unitary if A is symmetric and unitary.

7.3 Congruence and Unitary Congruence

Definitions:

Matrices $A, B \in \mathbb{C}^{n\times n}$ are **congruent** if there is a nonsingular $S \in \mathbb{C}^{n\times n}$ such that $A = SBS^T$; they are **unitarily congruent** if there is a unitary $U \in \mathbb{C}^{n\times n}$ such that $A = UBU^T$.

A matrix $A \in \mathbb{C}^{n\times n}$ is **conjugate normal** if $AA^* = \overline{A^*A}$; it is **congruence normal** if $A\bar{A}$ is normal.

If $A \in \mathbb{C}^{n\times n}$ is nonsingular, then its **cosquare** is $A^{-T}A$, in which $A^{-T} = (A^{-1})^T = (A^T)^{-1}$.

For each $k = 1, 2, \ldots$ define the real $k \times k$ matrix

$$\Gamma_k = \begin{bmatrix} 0 & & & & & (-1)^{k+1} \\ & & & & \iddots & (-1)^k \\ & & & -1 & \iddots & \\ & & 1 & 1 & & \\ & -1 & -1 & & & \\ 1 & 1 & & & & 0 \end{bmatrix}.$$

The smallest blocks of this form are $\Gamma_1 = [1]$ and $\Gamma_2 = \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix}$.

Facts:

Facts for which no specific reference is given can be found in [HJ13, Chap. 4].

1. Congruence and unitary congruence are equivalence relations.
2. *Congruence canonical form:* Each square complex matrix is congruent to a direct sum, uniquely determined up to permutation of direct summands, of matrices of the following three types:

   Type 0: $J_k(0)$, $k = 1, 2, \ldots$;

   Type I: Γ_k, $k = 1, 2, \ldots$; and

   Type II: $H_{2k}(\mu)$, $k = 1, 2, \ldots$, in which $0 \neq \mu \neq (-1)^{k+1}$ and μ is determined up to replacement by μ^{-1}.
3. An algorithm to determine the congruence canonical form of a square complex matrix is in [HS06].
4. Nonsingular complex matrices of the same size are congruent if and only if their cosquares are similar.
5. *Real congruence canonical form:* Each square real matrix A is congruent, via a real matrix, to a direct sum of five types of real blocks that are determined by the *congruence canonical form of A. For details, see [HS08, Theorem 2.1(d)].
6. If real matrices $A, B \in \mathbb{R}^{n\times n}$ are *congruent, then they are congruent via a real congruence. If $S \in \mathbb{C}^{n\times n}$ is nonsingular and $A = SBS^*$, and if $S = RE$ is a circular polar decomposition (Fact 7.5.4) with real factor R, then $A = RBR^T$.
7. If real matrices $A, B \in \mathbb{R}^{n\times n}$ are unitarily similar, then they are real orthogonally similar. If $U \in \mathbb{C}^{n\times n}$ is unitary and $A = UBU^*$, and if $U = RE$ is a circular polar decomposition (Fact 7.5.4) with real factor R, then R is orthogonal and $A = RBR^T$.
8. *Youla's Theorem:* Each matrix $A \in \mathbb{C}^{n\times n}$ is unitarily congruent to a quasitriangular matrix of the form $\begin{bmatrix} \Delta & \star \\ 0 & \Gamma \end{bmatrix}$, in which $\Delta = [d_{ij}]$ is upper triangular and has real nonnegative diagonal entries d_{ii}, and $\Gamma = [\Gamma_{ij}]$ is block upper triangular with 2×2 diagonal blocks Γ_{ii}. Each d_{ii}^2 is a real nonnegative eigenvalue of $A\bar{A}$. The eigenvalues of each matrix $\Gamma_{ii}\bar{\Gamma}_{ii}$ are eigenvalues of $A\bar{A}$; they are either an equal real negative pair or a non-real conjugate pair. Each block Γ_{ii} may be chosen to have one of four special forms; see [HJ13, Theorem 4.4.9].
9. Each symmetric $A \in \mathbb{C}^{n\times n}$ is unitarily congruent to a nonnegative diagonal matrix that is unique up to permutation of its diagonal entries, which are the singular values of A.
10. Each skew-symmetric complex matrix is unitarily congruent to a direct sum, uniquely determined up to permutation of direct summands, of matrices of the form $[0]$ or $\sigma H_2(-1)$, in which σ is real and positive.
11. Each conjugate-normal matrix is unitarily congruent to a direct sum, uniquely determined up to permutation of direct summands, of matrices of the form $[\sigma]$ or $\tau\begin{bmatrix} a & b \\ -b & a \end{bmatrix}$, in which σ, τ, a, b are real scalars such that $\sigma > 0$, $\tau > 0$, $a \geq 0$, $0 < b \leq 1$, and $a^2 + b^2 = 1$. The parameters in the blocks of this direct sum are uniquely determined by the eigenvalues of $A\bar{A}$. Alternatively, the 2×2 blocks may be taken to be $\tau H_2(e^{i\theta})$ with $\tau > 0$ and $0 < \theta \leq \pi$.
12. A matrix is conjugate normal if and only if it is unitarily congruent to a real normal matrix.
13. Let $A \in \mathbb{C}^{n\times n}$ and let $B = \begin{bmatrix} 0 & A \\ \bar{A} & 0 \end{bmatrix}$. Then A is conjugate normal if and only if B is normal; A is normal if and only if B is conjugate normal.

14. [HS09] Each congruence-normal matrix is unitarily congruent to a direct sum of matrices of the form $[\sigma]$ or $\tau H_2(\mu)$, in which σ and τ are real, $\mu \in \mathbb{C}$, $\sigma \geq 0$, $\tau > 0$, and $\mu \neq 1$. This direct sum is uniquely determined up to permutation of its blocks and replacement of any nonzero parameter μ by μ^{-1}, with a corresponding replacement of τ by $\tau|\mu|$.
15. If $A \in \mathbb{C}^{n\times n}$ is congruence normal, the eigenvalues of $A\bar{A}$ need not determine the unitary congruence equivalence class of A; see Example 6.
16. Each conjugate-normal matrix is congruence normal.
17. If nonsingular complex matrices of the same size are unitarily congruent, then their cosquares are unitarily similar.
18. [HS09, Sect. 8.8] The problem of classifying, under unitary congruence, square complex matrices A such that $A\bar{A}A$ is normal is unitarily wild, so it may be considered to be hopeless.
19. [HS08] Canonical forms under congruence are known for matrices over any algebraically closed or real closed field.

Examples:

1. The matrices $[1]$ and $[-1]$ are congruent (via $S = [i]$).
2. Complex symmetric and skew-symmetric matrices are conjugate normal.
3. It follows from Fact 14 that if $A \in \mathbb{C}^{n\times n}$ and $A\bar{A}$ is Hermitian, then A is unitarily congruent to a direct sum of matrices of the form $[\sigma]$ or $\tau H_2(\mu)$, in which σ, τ, μ are real, $\sigma \geq 0$, $\tau > 0$, $\mu \in [-1, 1)$.
4. The preceding example ensures that if $A \in \mathbb{C}^{n\times n}$ and $A\bar{A} = 0$, then A is unitarily congruent to a direct sum of matrices of the form $[0]$ or $\tau H_2(0)$, in which τ is real and positive.
5. The matrix $H_2(\mu)$ is congruence normal for all complex μ; it is conjugate normal if and only if $|\mu| = 1$.
6. Consider the congruence-normal matrices $A = 2H_2(4)$ and $B = H_2(16)$. The matrices $A\bar{A}$ and $B\bar{B}$ have the same eigenvalues, but the cosquares $A^{-T}A$ and $B^{-T}B$ do not. Consequently, A and B are not congruent; in particular, they are not unitarily congruent.

7.4 Consimilarity

Suppose that $A, B \in \mathbb{C}^{n\times n}$, A is Hermitian, and B is symmetric. When is there a nonsingular $S \in \mathbb{C}^{n\times n}$ such that SAS^* and SBS^T are both diagonal? A calculation reveals that the following condition is necessary: there is a nonsingular $T \in \mathbb{C}^{n\times n}$ such that $T(A^{-1}B)\bar{T}^{-1}$ is diagonal. This condition is also sufficient to ensure the asserted simultaneous diagonalization, and it motivates the following definitions.

Definitions:

Matrices $A, B \in \mathbb{C}^{n\times n}$ are **consimilar** if there is a nonsingular $S \in \mathbb{C}^{n\times n}$ such that $A = SB\bar{S}^{-1}$.

A matrix $A \in \mathbb{C}^{n\times n}$ is **contriangularizable** if there is a nonsingular $S \in \mathbb{C}^{n\times n}$ such that $S^{-1}A\bar{S}$ is upper triangular; it is **condiagonalizable** if there is a nonsingular $S \in \mathbb{C}^{n\times n}$ such that $S^{-1}A\bar{S}$ is diagonal.

Facts:

Facts for which no specific reference is given can be found in [HJ13, Chap. 4].

1. Consimilarity is an equivalence relation.
2. Unitary consimilarity is the same as unitary congruence.

3. A matrix $A \in \mathbb{C}^{n\times n}$ is contriangularizable if and only if every eigenvalue of $A\bar{A}$ is real and nonnegative.
4. A matrix $A \in \mathbb{C}^{n\times n}$ is condiagonalizable if and only if every eigenvalue of $A\bar{A}$ is real and nonnegative, $A\bar{A}$ is diagonalizable by similarity, and $\operatorname{rank} A = \operatorname{rank} A\bar{A}$.
5. *Canonical form under consimilarity:* Each $A \in \mathbb{C}^{n\times n}$ is consimilar to a direct sum, uniquely determined up to permutation of direct summands, of matrices of the following three types:

   Type 0: $J_k(0)$, $k = 1, 2, \ldots$;
   Type I: $J_k(\sigma)$, $k = 1, 2, \ldots$, in which σ is real and positive; and
   Type II: $H_{2k}(\mu)$, $k = 1, 2, \ldots$, in which $\mu \in \mathbb{C}\backslash[0, \infty)$.
6. Matrices $A, B \in \mathbb{C}^{n\times n}$ are consimilar if and only if $A\bar{A}$ is similar to $B\bar{B}$, $\operatorname{rank} A = \operatorname{rank} B$, and $\operatorname{rank}((A\bar{A})^k A) = \operatorname{rank}((B\bar{B})^k B)$ for each $k = 1, \ldots, [n/2]$. If A and B are nonsingular, then A is consimilar to B if and only if $A\bar{A}$ is similar to $B\bar{B}$.
7. Each $A \in \mathbb{C}^{n\times n}$ is consimilar to $-A$, to $\bar{A}$, to A^T, to A^*, to a Hermitian matrix, and to a real matrix.
8. Matrices $A, B \in \mathbb{C}^{n\times n}$ are consimilar if and only if $\begin{bmatrix} 0 & A \\ \bar{A} & 0 \end{bmatrix}$ is similar to $\begin{bmatrix} 0 & B \\ \bar{B} & 0 \end{bmatrix}$.

Examples:

1. A real similarity of two square complex matrices is a consimilarity.
2. The matrices $[1]$ and $[-1]$ are consimilar (via $S = [i]$), but they are not similar.
3. The Jordan canonical form of $A = \begin{bmatrix} 1 & i \\ i & -1 \end{bmatrix}$ is $J_2(0)$. The canonical form of A under consimilarity is $J_1(2) \oplus J_1(0)$; $A = S \begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix} \bar{S}^{-1}$ with $S = \begin{bmatrix} 1 & i \\ i & 1 \end{bmatrix}$.

7.5 Polar Decompositions

The classical polar decomposition (polar form) of a not-necessarily-square matrix appears in Chapter 24. We discuss it here in the company of two other matrix factorizations that share some common features with it.

Definitions:

A matrix $E \in \mathbb{C}^{n\times n}$ is **coninvolutory** if $E\bar{E} = I$.

A matrix $Q \in \mathbb{C}^{n\times n}$ is **complex orthogonal** if $QQ^T = I$.

The region $\mathcal{D} = \{z \in \mathbb{C} : \operatorname{Re} z > 0\} \cup \{z \in \mathbb{C} : \operatorname{Re} z = 0 \text{ and } \operatorname{Im} z > 0\}$ is the open right half plane together with the open positive imaginary axis.

Facts:

Facts for which no specific reference is given can be found in [HJ91, Sect. 6.4]. Let $A \in \mathbb{C}^{n\times n}$.

1. *Classical polar decomposition*: There are unique positive semidefinite matrices P_L and P_R, and a unitary matrix U, such that $A = P_L U = U P_R$. We have $P_L = (AA^*)^{1/2}$ and $P_R = (A^*A)^{1/2}$. If A is nonsingular, then P_L and P_R are nonsingular, U is unique, and $U = P_L^{-1} A = A P_R^{-1}$.
2. *Algebraic polar decomposition; nonsingular case*: If A is nonsingular, there are unique complex symmetric matrices S_L and S_R with eigenvalues in $\mathcal{D}$, and a unique complex orthogonal matrix Q, such that $A = S_L Q = Q S_R$. We have $S_L = (AA^T)^{1/2}$, $S_R = (A^T A)^{1/2}$, and $Q = S_L^{-1} A = A S_R^{-1}$.

3. *Algebraic polar decomposition; singular case*: If A is singular, the following statements are equivalent:
   (a) There are complex symmetric matrices S_L and S_R, and complex orthogonal matrices Q_L and Q_R, such that $A = S_L Q_R = Q_L S_R$.
   (b) $A^T A$ is similar to AA^T.
4. *Circular polar decomposition; nonsingular case*: If A is nonsingular, there are unique coninvolutory matrices E_L and E_R with eigenvalues in $\mathcal{D}$, and a unique real matrix R, such that $A = E_L R = R E_R$. We have $E_L = (A\bar{A}^{-1})^{1/2}$, $E_R = (\bar{A}^{-1}A)^{1/2}$, and $R = \bar{E}_L A = A\bar{E}_R$.
5. *Circular polar decomposition; singular case*: If A is singular, there is a coninvolutory matrix E and a real matrix R such that $A = ER$ if and only if $\operatorname{range} A = \operatorname{range} \bar{A}$.

Examples:

1. Let $A = \begin{bmatrix} 1 & 2i \\ -2i & 1 \end{bmatrix}$. Then $P_L = P_R = \begin{bmatrix} 2 & i \\ -i & 2 \end{bmatrix}$ and $U = \begin{bmatrix} 0 & i \\ -i & 0 \end{bmatrix}$; $S_L = S_R = i\sqrt{3}I$ and $Q = \frac{-i}{\sqrt{3}}A$; $E_L = E_R = \frac{1}{\sqrt{3}}\begin{bmatrix} 2i & -1 \\ 1 & 2i \end{bmatrix}$ and $R = \sqrt{3}\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$.
2. The matrix $A = \begin{bmatrix} 0 & i \\ 0 & 1 \end{bmatrix}$ has neither an algebraic polar decomposition nor a circular polar decomposition.

8.1 Unitary Similarity 8-1
8.2 Normal Matrices and Spectral Theory 8-5
References.. 8-10

Unitary transformations preserve the inner product. Hence, they preserve metric quantities that stem from the inner product, such as length, distance, and angle. While a general similarity preserves algebraic features of a linear transformation, such as the characteristic and minimal polynomials, the rank, and the Jordan canonical form, unitary similarities also preserve metric features such as the norm, singular values, and the numerical range. Unitary similarities are desirable in computational linear algebra for stability reasons.

Normal transformations are those that have an orthogonal basis of eigenvectors and, thus, can be represented by diagonal matrices relative to an orthonormal basis. The class of normal transformations includes Hermitian, skew-Hermitian, and unitary transformations; studying normal transformations and matrices leads to a more unified understanding of all of these special types of transformations. Often, results that are discovered first for Hermitian matrices can be generalized to the class of normal matrices. Since normal matrices are unitarily similar to diagonal matrices, things that are obviously true for diagonal matrices often hold for normal matrices as well; for example, the singular values of a normal matrix are the absolute values of the eigenvalues. Normal matrices have two important properties — diagonalizability and an orthonormal basis of eigenvectors — that tend to make life easier in both theoretical and computational situations.

8.1 Unitary Similarity

In this section, all matrices are over the complex numbers and are square. All vector spaces are finite dimensional complex inner product spaces.

Definitions:

A matrix U is **unitary** if $U^*U = I$.

A matrix Q is **orthogonal** if $Q^TQ = I$. *Note:* This extends the definition of orthogonal matrix given earlier in Section 5.2 for real matrices.

Matrices A and B are **unitarily similar** if $B = U^*AU$ for some unitary matrix U. Although the term *unitarily equivalent* is sometimes used in the literature, it is best to reserve that term for the relation $B = UAV$, in which U and V are unitary; see Chapter 7.

The **numerical range** of A is $W(A) = \{\mathbf{v}^*A\mathbf{v} | \mathbf{v}^*\mathbf{v} = 1\}$ (see Chapter 25 for more information about the numerical range).

The **Frobenius (Eulidean) norm** of the matrix A is $\|A\|_F = \left(\sum_{i,j=1}^{n} |a_{ij}|^2\right)^{1/2} = \left(tr(A^*A)\right)^{1/2}$. (See Chapter 50 for more information on norms.)

The **operator norm** of the matrix A induced by the vector 2-norm $\|\cdot\|_2$ is $\|A\|_2 = \max\{\|A\mathbf{v}\| \mid \|\mathbf{v}\| = 1\}$; this norm is also called the **spectral norm**.

Facts:

Most of the material in this section can be found in one or more of the following: [HJ13, Chap. 2], [Hal87, Chap. 3], [Gan59, Chap. IX], [MM64, I.4, III.5]. Specific references are also given for some facts.

1. A real, orthogonal matrix is unitary.
2. The following are equivalent:
   (a) U is unitary.
   (b) U is invertible and $U^{-1} = U^*$.
   (c) The columns of U are orthonormal.
   (d) The rows of U are orthonormal.
   (e) For any vectors $\mathbf{x}$ and $\mathbf{y}$, we have $\langle U\mathbf{x}, U\mathbf{y}\rangle = \langle \mathbf{x}, \mathbf{y}\rangle$.
   (f) For any vector $\mathbf{x}$, we have $\|U\mathbf{x}\| = \|\mathbf{x}\|$.
3. If U is unitary, then U^*, U^T, and $\bar{U}$ are also unitary.
4. If U is unitary, then every eigenvalue of U has modulus 1 and $|\det(U)| = 1$. Also, $\|U\|_2 = 1$.
5. The product of two unitary matrices is unitary and the product of two orthogonal matrices is orthogonal.
6. The set of $n \times n$ unitary matrices, denoted $U(n)$, is a subgroup of $GL(n, \mathbb{C})$, called the unitary group. The subgroup of elements of $U(n)$ with determinant one is the special unitary group, denoted $SU(n)$. Similarly, the set of $n \times n$ real orthogonal matrices, denoted $O(n)$, is a subgroup of $GL(n, \mathbb{R})$, called the real, orthogonal group, and the subgroup of real, orthogonal matrices of determinant one is $SO(n)$, the special orthogonal group.
7. Let U be unitary. Then
   (a) $\|A\|_F = \|U^*AU\|_F$.
   (b) $\|A\|_2 = \|U^*AU\|_2$.
   (c) A and U^*AU have the same singular values, as well as the same eigenvalues.
   (d) $W(A) = W(U^*AU)$.
8. [Sch09] Any square, complex matrix A is unitarily similar to a triangular matrix. If $T = U^*AU$ is triangular, then the diagonal entries of T are the eigenvalues of A. The unitary matrix U can be chosen to get the eigenvalues in any desired order along the diagonal of T. Algorithm 1 gives a method for finding U, assuming that one knows how to find an eigenvalue and eigenvector, e.g., by exact methods for small matrices (Section 4.4), and how to find an orthonormal basis containing the given vector, e.g., by the Gram-Schmidt process (Section 5.5). This algorithm is designed to illuminate the result, not for computation with large matrices in finite precision arithmetic; for such problems, appropriate numerical methods should be used (cf. Section 56.2).

Algorithm 1: Unitary Triangularization

```
Input: $A \in \mathbb{C}^{n\times n}$.
Output: unitary $U$ such that $U^*AU = T$ is triangular.
1. $A_1 = A$.
2. FOR $k = 1, \ldots, n-1$
    (a) Find an eigenvalue and normalized eigenvector $\mathbf{x}$ of the $(n+1-k)\times(n+1-k)$ matrix $A_k$.
    (b) Find an orthonormal basis $\mathbf{x}, \mathbf{y}_2, \ldots, \mathbf{y}_{n+1-k}$ for $\mathbb{C}^{n+1-k}$.
    (c) $U_k = [\mathbf{x}, \mathbf{y}_2, \ldots, \mathbf{y}_{n+1-k}]$.
    (d) $\tilde{U}_k = I_{k-1} \oplus U_k \qquad (\tilde{U}_1 = U_1)$.
    (e) $B_k = U_k^* A_k U_k$.
    (f) $A_{k+1} = B_k(1)$, the $(n-k)\times(n-k)$ matrix obtained from $B_k$ by deleting the first row and column.
3. $U = \tilde{U}_1\tilde{U}_2, \ldots, \tilde{U}_{n-1}$.
```

9. (A strictly real version of the Schur unitary triangularization theorem) If A is a real matrix, then there is a real, orthogonal matrix Q such that Q^TAQ is block triangular, with the blocks of size 1×1 or 2×2. Each real eigenvalue of A appears as a 1×1 block of Q^TAQ and each nonreal pair of complex conjugate eigenvalues corresponds to a 2×2 diagonal block of Q^TAQ.
10. If $\mathcal{F}$ is a commuting family of matrices, then $\mathcal{F}$ is simultaneously unitarily triangularizable — i.e., there is a unitary matrix U such that U^*AU is triangular for every matrix A in $\mathcal{F}$. For the real version, see [HJ13, Theorem 2.3.6(b)]
11. [Lit53], [Mit53], [Sha91] Let $\lambda_1, \lambda_2, \ldots, \lambda_t$ be the distinct eigenvalues of A with multiplicities $m_1, m_2, \ldots, m_t$. Suppose U^*AU is block triangular with diagonal blocks $A_1, A_2, \ldots, A_t$, where A_i is size $m_i \times m_i$ and λ_i is the only eigenvalue of A_i for each i. Then the Jordan canonical form of A is the direct sum of the Jordan canonical forms of the blocks $A_1, A_2, \ldots, A_t$. *Note:* This conclusion also holds if the unitary similarity U is replaced by an ordinary similarity.
12. Let $\lambda_1, \lambda_2, \ldots, \lambda_n$ be the eigenvalues of the $n\times n$ matrix A and let $T = U^*AU$ be triangular. Then $\|A\|_F^2 = \sum_{i=1}^n |\lambda_i|^2 + \sum_{i<j} |t_{ij}|^2$. Hence, $\|A\|_F^2 \geq \sum_{i=1}^n |\lambda_i|^2$ and equality holds if and only if T is diagonal, or equivalently, if and only if A is normal (see Section 8.2).
13. A 2×2 matrix A with eigenvalues λ_1, λ_2 is unitarily similar to the triangular matrix $\begin{bmatrix} \lambda_1 & r \\ 0 & \lambda_2 \end{bmatrix}$, where $r = \sqrt{\|A\|_F^2 - (|\lambda_1|^2 + |\lambda_2|^2)}$. Note that r is real and nonnegative.
14. Two 2×2 matrices, A and B, are unitarily similar if and only if they have the same eigenvalues and $\|A\|_F = \|B\|_F$.
15. Any square matrix A is unitarily similar to a matrix in which all of the diagonal entries are equal to $\dfrac{tr(A)}{n}$.
16. [Spe40] Two $n\times n$ matrices, A and B, are unitarily similar if and only if $tr\ (\omega(A, A^*)) = tr\ (\omega(B, B^*))$ for every word $\omega(s,t)$ in two noncommuting variables.
17. [Pea62] Two $n\times n$ matrices, A and B, are unitarily similar if and only if $tr\ (\omega(A, A^*)) = tr\ (\omega(B, B^*))$ for every word $\omega(s,t)$ in two noncommuting variables of degree at most $2n^2$. Since the number of words of degree at most $2n^2$ is 4^{n^2}, this gives a complete set of unitary invariants for $n\times n$ complex matrices containing fewer than 4^{n^2} elements. The bound on the number of words needed was lowered to $\lceil \frac{(2n^2+4)}{3} \rceil$ by Laffey [Laf86]. More recently, Pappacena [Pap97] obtained the better bound $n\cdot\sqrt{\frac{2n^2}{n-1} + \frac{1}{4}} + \frac{n}{2} - 2$. See [DJ07] for a summary.

18. For 2×2 matrices, the number of words needed in Fact 17 is three; the words A, A^2 and AA^* are sufficient. This follows from Fact 14 and the fact that 2×2 matrices A and B have the same eigenvalues if and only if $tr(A) = tr(B)$ and $tr(A^2) = tr(B^2)$. For 3×3 matrices, Sibirskiĭ [Sib67] has given a set of seven words $(\{x,\ x^2,\ xx^*,\ x^3,\ x^2x^*,\ x^2(x^*)^2,\ x^2(x^*)^2xx^*\})$ that is sufficient, and has shown this set of seven words is minimal [DJ07]. For 4×4 matrices, 20 words are known to be sufficient; see [D07] or [HJ13, Theorem 2.2.8].

Examples:

1. The matrix $\frac{1}{\sqrt{2}}\begin{bmatrix} 1 & 1 \\ i & -i \end{bmatrix}$ is unitary but not orthogonal.
2. The matrix $\frac{1}{\sqrt{1+2i}}\begin{bmatrix} 1 & 1+i \\ 1+i & -1 \end{bmatrix}$ is orthogonal but not unitary.
3. Fact 13 shows that $A = \begin{bmatrix} 3 & 1 \\ 2 & 2 \end{bmatrix}$ is unitarily similar to $A = \begin{bmatrix} 4 & 1 \\ 0 & 1 \end{bmatrix}$.
4. For any nonzero r, the matrices $\begin{bmatrix} 3 & r \\ 0 & 2 \end{bmatrix}$ and $\begin{bmatrix} 3 & 0 \\ 0 & 2 \end{bmatrix}$ are similar, but not unitarily similar.
5. Let $A = \begin{bmatrix} -31 & 21 & 48 \\ -4 & 4 & 6 \\ -20 & 13 & 31 \end{bmatrix}$. Apply Algorithm 1 to A:

   Step 1. $A_1 = A$.

   Step 2. For

   $k = 1$: (a) $p_{A_1}(x) = x^3 - 4x^2 + 5x - 2 = (x-2)(x-1)^2$, so the eigenvalues are 1, 1, 2. From the reduced row echelon form of $A - I_3$, we see that $[3, 0, 2]^T$ is an eigenvector for 1 and, thus, $\mathbf{x} = [\frac{3}{\sqrt{13}}, 0, \frac{2}{\sqrt{13}}]^T$ is a normalized eigenvector.

   (b) One expects to apply the Gram–Schmidt process to a basis that includes $\mathbf{x}$ as the first vector to produce an orthonormal basis. In this example, it is obvious how to find an orthonormal basis for $\mathbb{C}^3$.

   (c) $U_1 = \begin{bmatrix} \frac{3}{\sqrt{13}} & 0 & -\frac{2}{\sqrt{13}} \\ 0 & 1 & 0 \\ \frac{2}{\sqrt{13}} & 0 & \frac{3}{\sqrt{13}} \end{bmatrix}$.

   (d) Unnecessary.

   (e) $B_1 = U_1^* A_1 U_1 = \begin{bmatrix} 1 & \frac{89}{\sqrt{13}} & 68 \\ 0 & 4 & 2\sqrt{13} \\ 0 & -\frac{3}{\sqrt{13}} & -1 \end{bmatrix}$.

   (f) $A_2 = \begin{bmatrix} 4 & 2\sqrt{13} \\ -\frac{3}{\sqrt{13}} & -1 \end{bmatrix}$.

   $k = 2$: (a) 1 is still an eigenvalue of A_2. From the reduced row echelon form of $A_2 - I_2$, we see that $[-2\sqrt{13}, 3]^T$ is an eigenvector for 1 and, thus, $\mathbf{x} = [-2\sqrt{\frac{13}{61}}, \frac{3}{\sqrt{61}}]^T$ is a normalized eigenvector.

   (b) Again, the orthonormal basis is obvious.

(c) $U_2 = \begin{bmatrix} -2\sqrt{\frac{13}{61}} & \frac{3}{\sqrt{61}} \\ \frac{3}{\sqrt{61}} & 2\sqrt{\frac{13}{61}} \end{bmatrix}$.

(d) $\tilde{U}_2 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -2\sqrt{\frac{13}{61}} & \frac{3}{\sqrt{61}} \\ 0 & \frac{3}{\sqrt{61}} & 2\sqrt{\frac{13}{61}} \end{bmatrix}$.

(e) $B_2 = \begin{bmatrix} 1 & -\frac{29}{\sqrt{13}} \\ 0 & 2 \end{bmatrix}$.

(f) Unnecessary.

Step 3. $U = \tilde{U}_1\tilde{U}_2 = \begin{bmatrix} \frac{3}{\sqrt{13}} & -\frac{6}{\sqrt{793}} & -\frac{4}{\sqrt{61}} \\ 0 & -2\sqrt{\frac{13}{61}} & \frac{3}{\sqrt{61}} \\ \frac{2}{\sqrt{13}} & \frac{9}{\sqrt{793}} & \frac{6}{\sqrt{61}} \end{bmatrix}$. $T = U^*AU = \begin{bmatrix} 1 & \frac{26}{\sqrt{61}} & \frac{2035}{\sqrt{793}} \\ 0 & 1 & -\frac{29}{\sqrt{13}} \\ 0 & 0 & 2 \end{bmatrix}$.

6. [HJ13, Sect. 2.3, Problem 7] Schur's theorem tells us that every complex, square matrix is unitarily similar to a triangular matrix. However, it is not true that every complex, square matrix is similar to a triangular matrix via a complex, orthogonal similarity. For, suppose $A = QTQ^T$, where Q is complex orthogonal and T is triangular. Let $\mathbf{q}$ be the first column of Q. Then $\mathbf{q}$ is an eigenvector of A and $\mathbf{q}^T\mathbf{q} = 1$. However, the matrix $A = \begin{bmatrix} 1 & i \\ i & -1 \end{bmatrix}$ has no such eigenvector; A is nilpotent and any eigenvector of A is a scalar multiple of $\begin{bmatrix} 1 \\ i \end{bmatrix}$.

8.2 Normal Matrices and Spectral Theory

In this section, all matrices are over the complex numbers and are square. All vector spaces are finite dimensional complex inner product spaces.

Definitions:

The matrix A is **normal** if $AA^* = A^*A$.

The matrix A is **Hermitian** if $A^* = A$.

The matrix A is **skew-Hermitian** if $A^* = -A$.

The linear operator, T, on the complex inner product space V is **normal** if $TT^* = T^*T$.

Two orthogonal projections, P and Q, are **pairwise orthogonal** if $PQ = QP = 0$. (See Section 5.4 for information about orthogonal projection.)

The matrices A and B are said to have **Property L** if their eigenvalues $\alpha_k, \beta_k, (k = 1, \ldots, n)$ may be ordered in such a way that the eigenvalues of $xA + yB$ are given by $x\alpha_k + y\beta_k$ for all complex numbers x and y.

Facts:

Most of the material in this section can be found in one or more of the following: [HJ13, Chap. 2], [Hal87, Chap. 3], [Gan59, Chap. IX], [MM64, I.4, III.3.5, III.5], [GJSW87]. Specific references are also given for some facts.

1. Diagonal, Hermitian, skew-Hermitian, and unitary matrices are all normal. Note that real symmetric matrices are Hermitian, real skew-symmetric matrices are skew-

Hermitian, and real, orthogonal matrices are unitary, so all of these matrices are normal.

2. If U is unitary, then A is normal if and only if U^*AU is normal.
3. Let T be a linear operator on the complex inner product space V. Let $\mathcal{B}$ be an ordered orthonormal basis of V and let $A = [T]_{\mathcal{B}}$. Then T is normal if and only if A is a normal matrix.
4. (Spectral Theorem) The following three versions are equivalent.
   (a) A matrix is normal if and only if it is unitarily similar to a diagonal matrix. (*Note:* This is sometimes taken as the definition of normal. See Fact 6 for a strictly real version.)
   (b) The matrix A is normal if and only if there is an orthonormal basis of eigenvectors of A.
   (c) Let $\lambda_1, \lambda_2, \ldots, \lambda_t$ be the distinct eigenvalues of A with algebraic multiplicities $m_1, m_2, \ldots, m_t$. Then A is normal if and only if there exist t pairwise orthogonal, orthogonal projections $P_1, P_2, \ldots, P_t$ such that $\sum_{i=1}^{t} P_i = I$, $\operatorname{rank}(P_i) = m_i$, and $A = \sum_{i=1}^{t} \lambda_i P_i$. (Note that the two orthogonal projections P and Q are pairwise orthogonal if and only if range(P) and range(Q) are orthogonal subspaces.)
5. (Principal Axes Theorem) A real matrix A is symmetric if and only if $A = QDQ^T$, where Q is a real, orthogonal matrix and D is a real, diagonal matrix. Equivalently, a real matrix A is symmetric if and only if there is a real, orthonormal basis of eigenvectors of A. Note that the eigenvalues of A appear on the diagonal of D, and the columns of Q are eigenvectors of A. The Principal Axes Theorem follows from the Spectral Theorem, and the fact that all of the eigenvalues of a Hermitian matrix are real.
6. (A strictly real version of the Spectral Theorem) If A is a real, normal matrix, then there is a real, orthogonal matrix Q such that Q^TAQ is block diagonal, with the blocks of size 1×1 or 2×2. Each real eigenvalue of A appears as a 1×1 block of Q^TAQ and each nonreal pair of complex conjugate eigenvalues $a \pm ib$ corresponds to a real 2×2 diagonal block $\begin{bmatrix} a & b \\ -b & a \end{bmatrix}$ of Q^TAQ.
7. The following are equivalent. See also Facts 4 and 8. See [GJSW87] and [EI98] for more equivalent conditions.
   (a) A is normal.
   (b) A^* can be expressed as a polynomial in A.
   (c) For any B, $AB = BA$ implies $A^*B = BA^*$.
   (d) Any eigenvector of A is also an eigenvector of A^*.
   (e) Each invariant subspace of A is also an invariant subspace of A^*.
   (f) For each invariant subspace, $\mathcal{V}$, of A, the orthogonal complement, $\mathcal{V}^\perp$, is also an invariant subspace of A.
   (g) $\langle A\mathbf{x}, A\mathbf{y}\rangle = \langle A^*\mathbf{x}, A^*\mathbf{y}\rangle$ for all vectors $\mathbf{x}$ and $\mathbf{y}$.
   (h) $\langle A\mathbf{x}, A\mathbf{x}\rangle = \langle A^*\mathbf{x}, A^*\mathbf{x}\rangle$ for every vector $\mathbf{x}$.
   (i) $\|A\mathbf{x}\| = \|A^*\mathbf{x}\|$ for every vector $\mathbf{x}$.
   (j) $A^* = UA$ for some unitary matrix U.
   (k) $\|A\|_F^2 = \sum_{i=1}^{n} |\lambda_i|^2$, where $\lambda_1, \lambda_2, \ldots, \lambda_n$ are the eigenvalues of A.
   (l) The singular values of A are $|\lambda_1|, |\lambda_2|, \ldots, |\lambda_n|$, where $\lambda_1, \lambda_2, \ldots, \lambda_n$ are the eigenvalues of A.
   (m) If $A = UP$ is a polar decomposition of A, then $UP = PU$. (See Section 9.4.)
   (n) A commutes with a normal matrix with distinct eigenvalues.

   (o) A commutes with a Hermitian matrix with distinct eigenvalues.

   (p) The Hermitian matrix $AA^* - A^*A$ is semidefinite (i.e., it does not have both positive and negative eigenvalues).

8. Let $H = \dfrac{A+A^*}{2}$ and $K = \dfrac{A-A^*}{2i}$. Then H and K are Hermitian and $A = H + iK$. The matrix A is normal if and only if $HK = KH$.
9. If A is normal, then

   (a) A is Hermitian if and only if all of the eigenvalues of A are real.

   (b) A is skew-Hermitian if and only if all of the eigenvalues of A are pure imaginary.

   (c) A is unitary if and only if all of the eigenvalues of A have modulus 1.

10. [HJ13, Sect. 2.5, Problem 57] If A is normal, then A is symmetric if and only if there is a real orthogonal matrix P such that P^TAP is diagonal. Thus, when a matrix is both normal and symmetric, it has an orthogonal basis of real eigenvectors.
11. [HJ13, Sect. 2.5, Problem 57] If A is normal, then A is skew-symmetric if and only if there is a real orthogonal matrix P such that P^TAP is a direct sum of 2×2 and 1×1 matrices, where each 2×2 diagonal block has the form $\begin{bmatrix} 0 & i\alpha \\ -i\alpha & 0 \end{bmatrix}$, while each 1×1 block is a zero. Each 2×2 block corresponds to a pair of eigenvalues, $\alpha, -\alpha$, of A, where $\alpha \neq 0$.
12. The matrix U is unitary if and only if $U = \exp(iH)$ where H is Hermitian.
13. If Q is a real matrix with $\det(Q) = 1$, then Q is orthogonal if and only if $Q = \exp(K)$, where K is a real, skew-symmetric matrix.
14. (Cayley's Formulas/Cayley Transform) If U is unitary and does not have -1 as an eigenvalue, then $U = (I + iH)(I - iH)^{-1}$, where $H = i(I - U)(I + U)^{-1}$ is Hermitian.
15. (Cayley's Formulas/Cayley Transform, real version) If Q is a real, orthogonal matrix which does not have -1 as an eigenvalue, then $Q = (I - K)(I + K)^{-1}$, where $K = (I - Q)(I + Q)^{-1}$ is a real, skew-symmetric matrix.
16. A triangular matrix is normal if and only if it is diagonal. More generally, if the block triangular matrix, $\begin{bmatrix} B_{11} B_{12} \\ 0 \; B_{22} \end{bmatrix}$ (where the diagonal blocks, B_{ii}, $i = 1, 2$, are square), is normal, then $B_{12} = 0$.
17. Let A be a normal matrix. Then the diagonal entries of A are the eigenvalues of A if and only if A is diagonal.
18. If A and B are normal and commute, then AB is normal. However, the product of two noncommuting normal matrices need not be normal. (See Example 3 next.)
19. If A is normal, then $\rho(A) = \|A\|_2$. Consequently, if A is normal, then $\rho(A) \geq |a_{ij}|$ for all i and j. The converses of both of these facts are false (see Example 4 next).
20. [MM64, p. 168], [MM55], [ST80] If A is normal, then $W(A)$ is the convex hull of the eigenvalues of A. The converse of this statement holds when $n \leq 4$, but not for $n \geq 5$.
21. [WW49], [MM64, p. 162] Let A be a normal matrix and suppose x is a vector such that $(Ax)_i = 0$ whenever $x_i = 0$. For each nonzero component, x_j, of x, define $\mu_j = \dfrac{(Ax)_j}{x_j}$. Note that μ_j is a complex number, which we regard as a point in the plane. Then any closed disk that contains all of the points μ_j must contain an eigenvalue of A.
22. [HW53] Let A and B be normal matrices with eigenvalues $\alpha_1, \ldots, \alpha_n$ and $\beta_1, \ldots, \beta_n$. Then

$$\min_{\sigma \in S_n} \sum_{i=1}^{n} |\alpha_i - \beta_{\sigma(i)}|^2 \leq \|A - B\|_F^2 \leq \max_{\sigma \in S_n} \sum_{i=1}^{n} |\alpha_i - \beta_{\sigma(i)}|^2,$$

where the minimum and maximum are over all permutations σ in the symmetric group S_n (i.e., the group of all permutations of $1, \ldots, n$).

23. [Sun82a], [Bha82] Let A and B be $n \times n$ normal matrices with eigenvalues $\alpha_1, \ldots, \alpha_n$ and $\beta_1, \ldots, \beta_n$. Let Λ_A, Λ_B be the diagonal matrices with diagonal entries $\alpha_1, \ldots, \alpha_n$ and $\beta_1, \ldots, \beta_n$, respectively. Let $\|\cdot\|$ be any unitarily invariant norm. Then, if $A - B$ is normal, we have
$$\min_P \|\Lambda_A - P^{-1}\Lambda_B P\| \leq \|A - B\| \leq \max_P \|\Lambda_A - P^{-1}\Lambda_B P\|,$$
where the maximum and minimum are over all $n \times n$ permutation matrices P.

   Observe that if A and B are Hermitian, then $A - B$ is also Hermitian and, hence, normal, so this inequality holds for all pairs of Hermitian matrices. However, Example 6 gives a pair of 2×2 normal matrices (with $A - B$ not normal) for which the inequality does not hold. Note that for the Frobenius norm, we get the Hoffman–Wielandt inequality in Fact 22, which does hold for all pairs of normal matrices.

   For the operator norm, $\|\cdot\|_2$, this gives the inequality
$$\min_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}| \leq \|A - B\|_2 \leq \max_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}|$$
(assuming $A - B$ is normal), which, for the case of Hermitian A and B, is a classical result of Weyl [Wey12].

24. [OS90], [BEK97], [BDM83], [BDK89], [Hol92], [AN86] Let A and B be normal matrices with eigenvalues $\alpha_1, \ldots, \alpha_n$ and $\beta_1, \ldots, \beta_n$, respectively. Using $\|A\|_2 \leq \|A\|_F \leq \sqrt{n}\|A\|_2$ together with the Hoffman–Wielandt inequality in Fact 22 yields
$$\frac{1}{\sqrt{n}} \min_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}| \leq \|A - B\|_2 \leq \sqrt{n} \max_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}|.$$
On the right-hand side, the factor $\sqrt{n}$ may be replaced by $\sqrt{2}$ and it is known that this constant is the best possible. On the left-hand side, the factor $\frac{1}{\sqrt{n}}$ may be replaced by the constant $\frac{1}{2.91}$, but the best possible value for this constant is still unknown. Thus, we have
$$\frac{1}{2.91} \min_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}| \leq \|A - B\|_2 \leq \sqrt{2} \max_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}|.$$
See also [Bha82], [Bha87], [BH85], [Sun82a], [Sun82b].

25. If A and B are normal matrices, then $AB = BA$ if and only if A and B have Property L. This was established for Hermitian matrices by Motzkin and Taussky [MT52] and then generalized to the normal case by Wiegmann [Wieg53]. For a stronger generalization see [Wiel53].

26. [Fri02] Let $a_{ij}, i = 1, \ldots, n, j = 1, \ldots, n$, be any set of $\frac{n(n+1)}{2}$ complex numbers. Then there exists an $n \times n$ normal matrix, N, such that $n_{ij} = a_{ij}$ for $i \leq j$. Thus, any upper triangular matrix A can be completed to a normal matrix.

27. [Bha87, p. 54] Let A be a normal $n \times n$ matrix and let B be an arbitrary $n \times n$ matrix such that $\|A - B\|_2 < \epsilon$. Then every eigenvalue of B is within distance ϵ of an eigenvalue of A. Example 7 next shows that this need not hold for an arbitrary pair of matrices.

28. There are various ways to measure the "nonnormality" of a matrix. For example, if A has eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_n$, the quantity $\sqrt{\|A\|_F^2 - \sum_{i=1}^n |\lambda_i|^2}$ is a natural

measure of nonnormality, as is $\|A^*A - AA^*\|_2$. One could also consider $\|A^*A - AA^*\|$ for other choices of norm, or look at $\min\{\|A - N\| : N \text{ is normal}\}$. Fact 8 suggests $\|HK - KH\|$ as a possible measure of nonnormality, while the polar decomposition (see Fact 7) $A = UP$ of A suggests $\|UP - PU\|$. See [EP87] for more measures of nonnormality and comparisons between them.

29. [Lin97], [FR96] For any $\epsilon > 0$ there is a $\delta > 0$ such that, for any $n \times n$ complex matrix A with $\|AA^* - A^*A\|_2 < \delta$, there is a normal matrix N with $\|N - A\|_2 < \epsilon$. Thus, a matrix which is approximately normal is close to a normal matrix.
30. [Hu94] (Compare to Fact 7.) The following properties of matrix A are equivalent.
    (a) A^* can be expressed as a degree one (linear) polynomial in A.
    (b) There are complex scalars α and β and a Hermitian matrix H such that $|\beta| = 1$ and $A = \alpha I + \beta H$.
    (c) A is normal and its eigenvalues all lie on a line in the complex plane.

Examples:

1. Let $A = \begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix}$ and $U = \frac{1}{\sqrt{2}}\begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$. Then $U^*AU = \begin{bmatrix} 4 & 0 \\ 0 & 2 \end{bmatrix}$ and $A = 4P_1 + 2P_2$, where the $P_i's$ are the pairwise orthogonal, orthogonal projection matrices
$$P_1 = U\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}U^* = \frac{1}{2}\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \quad \text{and} \quad P_2 = U\begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}U^* = \frac{1}{2}\begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}.$$
2. $A = \begin{bmatrix} 1 & 4+2i & 6 \\ 0 & 8+2i & 0 \\ 2 & -2i & 4i \end{bmatrix} = H + iK$, where $H = \begin{bmatrix} 1 & 2+i & 4 \\ 2-i & 8 & i \\ 4 & -i & 0 \end{bmatrix}$ and $K = \begin{bmatrix} 0 & 1-2i & -2i \\ 1+2i & 2 & -1 \\ 2i & -1 & 4 \end{bmatrix}$ are Hermitian.
3. $A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ and $B = \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix}$ are both normal matrices, but the product $AB = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$ is not normal.
4. Let $A = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$. Then $\rho(A) = 2 = \|A\|_2$, but A is not normal.
5. Let $Q = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}$. Put $U = \frac{1}{\sqrt{2}}\begin{bmatrix} 1 & i \\ i & 1 \end{bmatrix}$ and $D = \begin{bmatrix} e^{i\theta} & 0 \\ 0 & e^{-i\theta} \end{bmatrix}$. Then $Q = UDU^* = U\left(\exp i\begin{bmatrix} \theta & 0 \\ 0 & -\theta \end{bmatrix}\right)U^* = \exp i\left(U\begin{bmatrix} \theta & 0 \\ 0 & -\theta \end{bmatrix}U^*\right)$. Put $H = U\begin{bmatrix} \theta & 0 \\ 0 & -\theta \end{bmatrix}U^* = \begin{bmatrix} 0 & -i\theta \\ i\theta & 0 \end{bmatrix}$. Then H is Hermitian and $Q = \exp(iH)$. Also, $K = iH = \begin{bmatrix} 0 & \theta \\ -\theta & 0 \end{bmatrix}$ is a real, skew-symmetric matrix and $Q = \exp(K)$.
6. Here is an example from [Sun82b] showing that the condition that $A - B$ is normal cannot be dropped from Fact 23. Let $A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ and $B = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$. Then A is Hermitian with eigenvalues ± 1 and B is skew-Hermitian with eigenvalues $\pm i$. So, we have $\|\Lambda_A - P^{-1}\Lambda_B P\|_2 = \sqrt{2}$, regardless of the permutation P. However, $A - B = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$ and $\|A - B\|_2 = 2$.
7. This example shows that Fact 27 does not hold for general pairs of matrices. Let $\alpha > \beta > 0$ and put $A = \begin{bmatrix} 0 & \alpha \\ \beta & 0 \end{bmatrix}$ and $B = \begin{bmatrix} 0 & \alpha - \beta \\ 0 & 0 \end{bmatrix}$. Then the eigenvalues of A are $\pm\sqrt{\alpha\beta}$ and both

eigenvalues of B are zero. We have $A - B = \begin{bmatrix} 0 & \beta \\ \beta & 0 \end{bmatrix}$ and $\|A - B\|_2 = \beta$. But, since $\alpha > \beta$, we have $\sqrt{\alpha\beta} > \beta = \|A - B\|_2$.

Information on self-adjoint (i.e., Hermitian) and positive definite linear operators (usually called positive linear operators in the literature) can be found in Section 5.3. For a finite dimensional inner product space, an orthonormal basis provides a correspondence between matrix results and linear operators (see Fact 5.3.6).

9.1 Hermitian Matrices

All matrices in this section are either real or complex, unless explicitly stated otherwise.

Definitions:

A matrix $A \in \mathbb{C}^{n\times n}$ is **Hermitian** or **self-adjoint** if $A^* = A$, or element-wise, $\bar{a}_{ij} = a_{ji}$, for $i, j = 1, \ldots, n$. The set of Hermitian matrices of order n is denoted by $\mathcal{H}_n$. Note that a matrix $A \in \mathbb{R}^{n\times n}$ is Hermitian if and only if $A^T = A$.

A matrix $A \in \mathbb{C}^{n\times n}$ is **symmetric** if $A^T = A$, or element-wise, $a_{ij} = a_{ji}$, for $i, j = 1, \ldots, n$. The set of real symmetric matrices of order n is denoted by $\mathcal{S}_n$. Since $\mathcal{S}_n$ is a subset of $\mathcal{H}_n$, all theorems for matrices in $\mathcal{H}_n$ apply to $\mathcal{S}_n$ as well.

Let V be a complex inner product space with inner product $\langle \mathbf{v}, \mathbf{w}\rangle$ and let $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \in V$. The matrix $G = [g_{ij}] \in \mathbb{C}^{n\times n}$ defined by $g_{ij} = \langle \mathbf{v}_i, \mathbf{v}_j\rangle,\ \ i, j \in \{1, 2, \ldots, n\}$ is called the **Gram matrix** of the vectors $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n$.

The inner product $\langle \mathbf{x}, \mathbf{y}\rangle$ of two vectors $\mathbf{x}, \mathbf{y} \in \mathbb{C}^n$ will mean the standard inner product, i.e., $\langle \mathbf{x}, \mathbf{y}\rangle = \mathbf{y}^*\mathbf{x}$, unless stated otherwise. The term orthogonal will mean orthogonal with respect to this inner product, unless stated otherwise.

Facts:

For facts without a specific reference, see [HJ13, pp. 49, 131–135, 227–229, 232], [Lax96, pp. 80–83], and [GR01, pp. 169–171]. Many are an immediate consequence of the definition.

1. A real symmetric matrix is Hermitian, and a real Hermitian matrix is symmetric.
2. Let A, B be Hermitian.

   (a) Then $A + B$ is Hermitian.
   (b) If $AB = BA$, then AB is Hermitian.
   (c) If $c \in \mathbb{R}$, then cA is Hermitian.

3. $A + A^*$, $A^* + A$, AA^*, and A^*A are Hermitian for all $A \in \mathbb{C}^{n\times n}$.
4. If $A \in \mathcal{H}_n$, then $\langle A\mathbf{x}, \mathbf{y}\rangle = \langle \mathbf{x}, A\mathbf{y}\rangle$ for all $\mathbf{x}, \mathbf{y} \in \mathbb{C}^n$.
5. If $A \in \mathcal{H}_n$, then $A^k \in \mathcal{H}_n$ for all $k \in \mathbb{N}$.
6. If $A \in \mathcal{H}_n$ is invertible, then $A^{-1} \in \mathcal{H}_n$.
7. The main diagonal entries of a Hermitian matrix are real.
8. All eigenvalues of a Hermitian matrix are real.
9. Eigenvectors corresponding to distinct eigenvalues of a Hermitian matrix are orthogonal.
10. *Spectral Theorem — Diagonalization version:* If $A \in \mathcal{H}_n$, there is a unitary matrix $U \in \mathbb{C}^{n\times n}$ such that $U^*AU = D$, where D is a real diagonal matrix whose diagonal entries are the eigenvalues of A. If $A \in \mathcal{S}_n$, the same conclusion holds with an orthogonal matrix $Q \in \mathbb{R}^{n\times n}$, i.e., $Q^TAQ = D$.
11. *Spectral Theorem — Orthonormal basis version:* If $A \in \mathcal{H}_n$, there is an orthonormal basis of $\mathbb{C}^n$ consisting of eigenvectors of A. If $A \in \mathcal{S}_n$, the same conclusion holds with $\mathbb{C}^n$ replaced by $\mathbb{R}^n$.
12. [Lay12, p. 398] *Spectral Theorem — Sum of rank one projections version:* Let $A \in \mathcal{H}_n$ with eigenvalues $\lambda_1, \lambda_2, , \dots, \lambda_n$, and corresponding orthonormal eigenvectors $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$. Then
$$A = \lambda_1\, \mathbf{u}_1\mathbf{u}_1^* + \lambda_2\, \mathbf{u}_2\mathbf{u}_2^* + \cdots + \lambda_n\, \mathbf{u}_n\mathbf{u}_n^*.$$
    If $A \in \mathcal{S}_n$, then
$$A = \lambda_1\, \mathbf{u}_1\mathbf{u}_1^T + \lambda_2\, \mathbf{u}_2\mathbf{u}_2^T + \cdots + \lambda_n\, \mathbf{u}_n\mathbf{u}_n^T.$$
13. If $A \in \mathcal{H}_n$, then rank A equals the number of nonzero eigenvalues of A.
14. Each $A \in \mathbb{C}^{n\times n}$ can be written uniquely as $A = H + iK$, where $H, K \in \mathcal{H}_n$.
15. Given $A \in \mathbb{C}^{n\times n}$, then $A \in \mathcal{H}_n$ if and only if $\mathbf{x}^*A\mathbf{x}$ is real for all $\mathbf{x} \in \mathbb{C}^n$.
16. Any Gram matrix is Hermitian. Some examples of how Gram matrices arise are given in Chapter 83 and [Lax96, p. 124].
17. The properties given above for $\mathcal{H}_n$ and $\mathcal{S}_n$ are generally not true for symmetric matrices in $\mathbb{C}^{n\times n}$, but there is a substantial theory associated with them. (See [HJ13, Sects. 4.4 and 4.6].)

Examples:

1. The matrix $\begin{bmatrix} 3 & 2-i \\ 2+i & -5 \end{bmatrix} \in \mathcal{H}_2$ and $\begin{bmatrix} 6 & 0 & 2 \\ 0 & -1 & 5 \\ 2 & 5 & 3 \end{bmatrix} \in \mathcal{S}_3$.
2. Let D be an open set in $\mathbb{R}^n$ containing the point $\mathbf{x}_0$, and let $f : D \to \mathbb{R}$ be a twice continuously differentiable function on D. Define $H \in \mathbb{R}^{n\times n}$ by $h_{ij} = \dfrac{\partial^2 f}{\partial x_i \partial x_j}(\mathbf{x}_0.)$. Then H is a real symmetric matrix, and is called the *Hessian* of f.
3. Let $G = (V, E)$ be a simple undirected graph with vertex set $V = \{1, 2, 3, \dots, n\}$. The $n \times n$ *adjacency matrix* $\mathcal{A}_G = [a_{ij}]$ (see Section 39.3) is defined by
$$a_{ij} = \begin{cases} 1 & \text{if } ij \in E \\ 0 & \text{otherwise.} \end{cases}$$

In particular, all diagonal entries of $\mathcal{A}_G$ are 0. Since ij is an edge of G if and only if ji is, the adjacency matrix is real symmetric. Observe that for each $i \in V$, $\sum_{j=1}^{n} a_{ij} = \delta(i)$, i.e., the sum of the i^{th} row is the degree of vertex i.

9.2 Order Properties of Eigenvalues of Hermitian Matrices

Definitions:

Given $A \in \mathcal{H}_n$, the **Rayleigh quotient** $R_A : \mathbb{C}^n \backslash \{0\} \to \mathbb{R}$ is $R_A(x) = \dfrac{\mathbf{x}^* A\mathbf{x}}{\mathbf{x}^*\mathbf{x}} = \dfrac{\langle A\mathbf{x}, \mathbf{x}\rangle}{\langle \mathbf{x}, \mathbf{x}\rangle}$.

Given $A \in \mathcal{H}_n$, denote the n eigenvalues of A by $\lambda_1(A), \lambda_2(A), \ldots, \lambda_n(A)$, where $\lambda_1(A) \geq \lambda_2(A) \geq \cdots \geq \lambda_n(A)$.

Facts:

For facts without a specific reference, see [HJ13, Sects. 4.2, 4.3]; however, in that source the eigenvalues are labeled from smallest to greatest and the definition of majorizes (see Preliminaries) has a similar reversal of notation.

1. *Rayleigh–Ritz Theorem:* If $A \in \mathcal{H}_n$, then

$$\lambda_n(A) \leq \frac{\mathbf{x}^* A\mathbf{x}}{\mathbf{x}^*\mathbf{x}} \leq \lambda_1(A), \quad \text{for all nonzero } \mathbf{x} \in \mathbb{C}^n,$$

$$\lambda_1(A) = \max_{x \neq 0} \frac{\mathbf{x}^* A\mathbf{x}}{\mathbf{x}^*\mathbf{x}} = \max_{\|\mathbf{x}\|_2 = 1} \mathbf{x}^* A\mathbf{x},$$

and

$$\lambda_n(A) = \min_{x \neq 0} \frac{\mathbf{x}^* A\mathbf{x}}{\mathbf{x}^*\mathbf{x}} = \min_{\|\mathbf{x}\|_2 = 1} \mathbf{x}^* A\mathbf{x}.$$

2. *Courant–Fischer Theorem:* Let $A \in \mathcal{H}_n$, let $k \in \{1, \ldots, n\}$, and let W denote a subspace of $\mathbb{C}^n$. Then

$$\lambda_k(A) = \max_{\dim W = k} \ \min_{0 \neq \mathbf{x} \in W} \frac{\mathbf{x}^* A\mathbf{x}}{\mathbf{x}^*\mathbf{x}}$$

and

$$\lambda_k(A) = \min_{\dim W = n-k+1} \ \max_{0 \neq \mathbf{x} \in W} \frac{\mathbf{x}^* A\mathbf{x}}{\mathbf{x}^*\mathbf{x}}.$$

3. [HJ13, p. 239], [Bha01, p. 291] *Weyl Inequalities:* Let $A, B \in \mathcal{H}_n$. Then for every pair of integers j, k such that $1 \leq j, k \leq n$ and $j + k \leq n + 1$,

$$\lambda_{j+k-1}(A + B) \leq \lambda_j(A) + \lambda_k(B)$$

and for every pair of integers j, k such that $1 \leq j, k \leq n$ and $j + k \geq n + 1$,

$$\lambda_{j+k-n}(A + B) \geq \lambda_j(A) + \lambda_k(B).$$

4. *Weyl Inequalities:* These inequalities are a prominent special case of Fact 3. Let $A, B \in \mathcal{H}_n$. Then for each $j \in \{1, 2, \ldots, n\}$,

$$\lambda_j(A) + \lambda_n(B) \leq \lambda_j(A + B) \leq \lambda_j(A) + \lambda_1(B).$$

5. *Interlacing Inequalities:* Let $A \in \mathcal{H}_n$, let $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$ be the eigenvalues of A, and for any $i \in \{1, 2, \ldots, n\}$, let $\mu_1 \geq \mu_2 \geq \cdots \geq \mu_{n-1}$ be the eigenvalues of $A(i)$, where $A(i)$ is the principal submatrix of A obtained by deleting its i^{th} row and column. Then
$$\lambda_1 \geq \mu_1 \geq \lambda_2 \geq \mu_2 \geq \lambda_3 \geq \ldots \geq \lambda_{n-1} \geq \mu_{n-1} \geq \lambda_n.$$
6. Let $A \in \mathcal{H}_n$ and let B be any principal submatrix of A. If λ_k is the k^{th} largest eigenvalue of A and μ_k is the k^{th} largest eigenvalue of B, then $\lambda_k \geq \mu_k$.
7. Let $A \in \mathcal{H}_n$ with eigenvalues $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$. Let $\mathcal{S}$ be a k-dimensional subspace of $\mathbb{C}^n$ with $k \in \{1, 2, \ldots, n\}$. Then
   (a) If there is a constant c such that $\mathbf{x}^* A\mathbf{x} \geq c\mathbf{x}^*\mathbf{x}$ for all $\mathbf{x} \in \mathcal{S}$, then $\lambda_k \geq c$.
   (b) If there is a constant c such that $\mathbf{x}^* A\mathbf{x} \leq c\mathbf{x}^*\mathbf{x}$ for all $\mathbf{x} \in \mathcal{S}$, then $\lambda_{n-k+1} \leq c$.
8. Let $A \in \mathcal{H}_n$.
   (a) If $\mathbf{x}^* A\mathbf{x} \geq 0$ for all $\mathbf{x}$ in a k-dimensional subspace of $\mathbb{C}^n$, then A has at least k nonnegative eigenvalues.
   (b) If $\mathbf{x}^* A\mathbf{x} > 0$ for all nonzero $\mathbf{x}$ in a k-dimensional subspace of $\mathbb{C}^n$, then A has at least k positive eigenvalues.
9. Let $A \in \mathcal{H}_n$, let $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_n)$ be the vector of eigenvalues of A arranged in decreasing order, and let $\alpha = (a_1, a_2, \ldots, a_n)$ be the vector consisting of the diagonal entries of A arranged in decreasing order. Then $\lambda \succeq \alpha$. (See Preliminaries for the definition of $\succeq$.)
10. Let $\alpha = (a_1, a_2, \ldots, a_n)$, $\beta = (b_1, b_2, \ldots, b_n)$ be decreasing sequences of real numbers such that $\alpha \succeq \beta$. Then there exists an $A \in \mathcal{H}_n$ such that the eigenvalues of A are $a_1, a_2, \ldots, a_n$, and the diagonal entries of A are $b_1, b_2, \ldots, b_n$.
11. [Lax96, pp. 133–136] or [Bha01, p. 291] (See also Chapter 21.) Let $A, B \in \mathcal{H}_n$ with eigenvalues $\lambda_1(A) \geq \lambda_2(A) \geq \cdots \geq \lambda_n(A)$ and $\lambda_1(B) \geq \lambda_2(B) \geq \cdots \geq \lambda_n(B)$. Then
   (a) $|\lambda_i(A) - \lambda_i(B)| \leq ||A - B||_2, \; i = 1, \ldots, n.$
   (b) $\displaystyle\sum_{i=1}^{n} [\lambda_i(A) - \lambda_i(B)]^2 \leq ||A - B||_F^2.$

Examples:

1. Setting $\mathbf{x} = \mathbf{e}_i$ in the Rayleigh-Ritz theorem, we obtain $\lambda_n \leq a_{ii} \leq \lambda_1$. Thus, for any $A \in \mathcal{H}_n$, we have $\lambda_1 \geq \max\{a_{ii} | \, i \in \{1, 2, \ldots, n\}\}$ and $\lambda_n \leq \min\{a_{ii} | \, i \in \{1, 2, \ldots, n\}\}$.
2. Setting $\mathbf{x} = [1, 1, \ldots, 1]^T$ in the Rayleigh-Ritz theorem, we find that $\lambda_n \leq \frac{1}{n} \sum_{i,j=1}^{n} a_{ij} \leq \lambda_1$. If we take A to be the adjacency matrix of a graph, then this inequality implies that the largest eigenvalue of the graph is greater than or equal to its average degree.
3. The Weyl inequalities in Fact 3 are a special case of the following general class of inequalities:
$$\sum_{k \in K} \lambda_k(A + B) \leq \sum_{i \in I} \lambda_i(A) + \sum_{j \in J} \lambda_j(B),$$
where I, J, K are certain subsets of $\{1, 2, \ldots, n\}$. In 1962, A. Horn conjectured which inequalities of this form are valid for all Hermitian A, B, and this conjecture was proved correct in papers by A. Klyachko in 1998 and by A. Knutson and T. Tao in 1999. Two detailed accounts of the problem and its solution are given in [Bha01] and [Ful00].
4. Let $A = \begin{bmatrix} 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix}$ have eigenvalues $\lambda_1 \geq \lambda_2 \geq \lambda_3 \geq \lambda_4$. Since $A(4) = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$ has eigenvalues 3, 0, 0, by the interlacing inequalities, $\lambda_1 \geq 3 \geq \lambda_2 \geq 0 \geq \lambda_3 \geq 0 \geq \lambda_4$. In particular, $\lambda_3 = 0$.

Applications:

1. To use the Rayleigh–Ritz theorem effectively to estimate the largest or smallest eigenvalue of a Hermitian matrix, one needs to take into account the relative magnitudes of the entries of the matrix. For example, let $A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 2 & 2 \\ 1 & 2 & 3 \end{bmatrix}$. In order to estimate λ_1, we should try to maximize the Rayleigh quotient. A vector $\mathbf{x} \in \mathbb{R}^3$ is needed for which no component is zero, but such that each component is weighted more than the last. In a few trials, one is led to $\mathbf{x} = [1, 2, 3]^T$, which gives a Rayleigh quotient of 5. So $\lambda_1 \geq 5$. This is close to the actual value of λ_1, which is $\frac{1}{4} \csc^2 \frac{\pi}{14} \approx 5.049$.

   This example is only meant to illustrate the method; its primary importance is as a tool for estimating the largest (smallest) eigenvalue of a large Hermitian matrix when it can neither be found exactly nor be computed numerically.
2. The interlacing inequalities can sometimes be used to efficiently find all the eigenvalues of a Hermitian matrix. The Laplacian matrix (from spectral graph theory, see Section 39.4) of a star is $L = \begin{bmatrix} n-1 & -1 & -1 & \cdots & -1 & -1 \\ -1 & 1 & 0 & \cdots & 0 & 0 \\ -1 & 0 & 1 & & 0 & 0 \\ \vdots & \vdots & & \ddots & & \vdots \\ -1 & 0 & 0 & & 1 & 0 \\ -1 & 0 & 0 & \ldots & 0 & 1 \end{bmatrix}$.

   Since $L(1)$ is an identity matrix, the interlacing inequalities relative to $L(1)$ are: $\lambda_1 \geq 1 \geq \lambda_2 \geq 1 \geq \ldots \geq \lambda_{n-1} \geq 1 \geq \lambda_n$. Therefore, $n-2$ of the eigenvalues of L are equal to 1. Since the columns sum to 0, another eigenvalue is 0. Finally, since tr $L = 2n - 2$, the remaining eigenvalue is n.
3. Fact 6 is applied in spectral graph theory to establish the useful fact that the k^{th} largest eigenvalue of a graph is greater than or equal to the k^{th} largest eigenvalue of any induced subgraph.

9.3 Congruence and Inertia

Definitions:

Two matrices $A, B \in \mathcal{H}_n$ are ***congruent** if there is an invertible matrix $C \in \mathbb{C}^{n\times n}$ such that $B = C^*AC$, denoted $A \overset{c}{\sim} B$. If C is real, then A and B are also called **congruent**.

Let $A \in \mathcal{H}_n$. The **inertia** of A is the ordered triple $\text{in}(A) = (\pi(A), \nu(A), \delta(A))$, where $\pi(A)$ is the number of positive eigenvalues of A, $\nu(A)$ is the number of negative eigenvalues of A, and $\delta(A)$ is the number of zero eigenvalues of A.

Facts:

Many of the following can be found in [HJ13, pp. 281–282] and a variation of Sylvester's Law in [Lax96, pp. 77–78].

1. Unitary similarity is a special case of *congruence.
2. *Congruence is an equivalence relation.
3. For $A \in \mathcal{H}_n$, $\pi(A) + \nu(A) + \delta(A) = n$.
4. For $A \in \mathcal{H}_n$, $\operatorname{rank} A = \pi(A) + \nu(A)$.
5. The inertias of an invertible Hermitian matrix and its inverse are the same.

6. The inertias of similar Hermitian matrices are the same.
7. Let $A \in \mathcal{H}_n$ with inertia (r, s, t). Then A is *congruent to $I_r \oplus (-I_s) \oplus 0_t$. A matrix C that implements this *congruence is found as follows. Let U be a unitary matrix for which $U^*AU = D$ is a diagonal matrix with $d_{11}, \ldots, d_{rr}$ the positive eigenvalues, $d_{r+1,r+1}, \ldots, d_{r+s,r+s}$ the negative eigenvalues, and $d_{ii} = 0,\ k > r + s$. Let
$$s_i = \begin{cases} 1/\sqrt{d_{ii}}, & i = 1, \ldots, r \\ 1/\sqrt{-d_{ii}}, & i = r+1, \ldots, s \\ 1, & i > r+s \end{cases}$$
and let $S = \operatorname{diag}(s_1, s_2, \ldots, s_n)$. Then $C = US$.
8. *Sylvester's Law of Inertia:* Two matrices $A, B \in \mathcal{H}_n$ are *congruent if and only if they have the same inertia.
9. *Subadditivity of Inertia:* Let $A, B \in \mathcal{H}_n$. Then
$$\pi(A+B) \le \pi(A) + \pi(B) \quad \text{and} \quad \nu(A+B) \le \nu(A) + \nu(B).$$
This is a straightforward corollary of 9.2.3.
10. If $A \in \mathcal{H}_n$ and B is a principal submatrix of A, then $\pi(B) \le \pi(A)$ and $\nu(B) \le \nu(A)$. This is a corollary of 9.2.5.

Examples:

1. Let $A = \begin{bmatrix} 0 & 0 & 3 \\ 0 & 0 & 4 \\ 3 & 4 & 0 \end{bmatrix}$. Since $\operatorname{rank} A = 2$, $\pi(A) + \nu(A) = 2$, so $\delta(A) = 1$. Since $\operatorname{tr} A = 0$, we have $\pi(A) = \nu(A) = 1$, and $\operatorname{in}(A) = (1, 1, 1)$. Letting
$$C = \begin{bmatrix} \frac{3}{5\sqrt{10}} & \frac{3}{5\sqrt{10}} & \frac{4}{5} \\ \frac{4}{5\sqrt{10}} & \frac{4}{5\sqrt{10}} & -\frac{3}{5} \\ \frac{1}{\sqrt{10}} & -\frac{1}{\sqrt{10}} & 0 \end{bmatrix}$$
we have
$$C^*AC = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$
Now suppose
$$B = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}.$$
Clearly $\operatorname{in}(B) = (1, 1, 1)$ also. By Sylvester's law of inertia, B must be *congruent to A.

9.4 Positive Definite Matrices

Definitions:

A matrix $A \in \mathcal{H}_n$ is

- **positive definite** if $\mathbf{x}^*A\mathbf{x} > 0$ for all nonzero $\mathbf{x} \in \mathbb{C}^n$.
- **positive semidefinite** if $\mathbf{x}^*A\mathbf{x} \ge 0$ for all $\mathbf{x} \in \mathbb{C}^n$.
- **indefinite** if neither A nor $-A$ is positive semidefinite.

The set of positive definite matrices of order n is denoted by PD_n, and the set of positive semidefinite matrices of order n by PSD_n. If the dependence on n is not significant, these can be abbreviated as PD and PSD.

Finally, PD (PSD) is also used to abbreviate "positive definite" ("positive semidefinite").

Let k be a positive integer. If A, B are PSD and $B^k = A$, then B is called a **PSD k^{th} root** of A and is denoted $A^{1/k}$.

A **correlation matrix** is a PSD matrix in which every main diagonal entry is 1.

Facts:

For facts without a specific reference, see [HJ13, Sects. 7.1 and 7.2] and [Fie86, pp. 51–57].

1. $A \in \mathcal{S}_n$ is PD if $\mathbf{x}^T A\mathbf{x} > 0$ for all nonzero $\mathbf{x} \in \mathbb{R}^n$, and is PSD if $\mathbf{x}^T A\mathbf{x} \geq 0$ for all $\mathbf{x} \in \mathbb{R}^n$.
2. Let $A, B \in \mathrm{PSD}_n$.
   (a) Then $A + B \in \mathrm{PSD}_n$.
   (b) If, in addition, $A \in \mathrm{PD}_n$, then $A + B \in \mathrm{PD}_n$.
   (c) If $c \geq 0$, then $cA \in \mathrm{PSD}_n$.
   (d) If, in addition, $A \in \mathrm{PD}_n$ and $c > 0$, then $cA \in \mathrm{PD}_n$.
3. If $A_1, A_2, \ldots, A_k \in \mathrm{PSD}_n$, then so is $A_1 + A_2 + \cdots + A_k$. If, in addition, there is an $i \in \{1, 2, \ldots, k\}$ such that $A_i \in \mathrm{PD}_n$, then $A_1 + A_2 + \cdots + A_k \in \mathrm{PD}_n$.
4. Let $A \in \mathcal{H}_n$. Then A is PD if and only if every eigenvalue of A is positive, and A is PSD if and only if every eigenvalue of A is nonnegative.
5. If A is PD, then $\operatorname{tr} A > 0$ and $\det A > 0$. If A is PSD, then $\operatorname{tr} A \geq 0$ and $\det A \geq 0$.
6. A PSD matrix is PD if and only if it is invertible.
7. *Inheritance Principle:* Any principal submatrix of a PD (PSD) matrix is PD (PSD).
8. All principal minors of a PD (PSD) matrix are positive (nonnegative).
9. Each diagonal entry of a PD (PSD) matrix is positive (nonnegative). If a diagonal entry of a PSD matrix is 0, then every entry in the row and column containing it is also 0.
10. Let $A \in \mathcal{H}_n$. Then A is PD if and only if every leading principal minor of A is positive. A is PSD if and only if every principal minor of A is nonnegative. (The matrix $\begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix}$ shows that it is not sufficient that every leading principal minor be nonnegative in order for A to be PSD.)
11. Let A be PD (PSD). Then A^k is PD (PSD) for all $k \in \mathbb{N}$.
12. Let $A \in \mathrm{PSD}_n$ and express A as $A = UDU^*$, where U is unitary and D is the diagonal matrix of eigenvalues. Given any positive integer k, there exists a unique **PSD k^{th} root** of A given by $A^{1/k} = UD^{1/k}U^*$. If A is real so is $A^{1/k}$. (See also Section 17.2.)
13. If A is PD, then A^{-1} is PD.
14. Let $A \in \mathrm{PSD}_n$ and let $C \in \mathbb{C}^{n\times m}$. Then C^*AC is PSD.
15. Let $A \in \mathrm{PD}_n$ and let $C \in \mathbb{C}^{n\times m}$, $n \geq m$. Then C^*AC is PD if and only if rank C = m; i.e., if and only if C has linearly independent columns.
16. Let $A \in \mathrm{PD}_n$ and $C \in \mathbb{C}^{n\times n}$. Then C^*AC is PD if and only if C is invertible.
17. Let $A \in \mathcal{H}_n$. Then A is PD if and only if there is an invertible $B \in \mathbb{C}^{n\times n}$ such that $A = B^*B$.
18. *Cholesky Factorization:* Let $A \in \mathcal{H}_n$. Then A is PD if and only if there is an invertible lower triangular matrix L with positive diagonal entries such that $A = LL^*$. (See Chapter 51 for information on the computation of the Cholesky factorization.)

19. Let $A \in \mathrm{PSD}_n$ with rank A = r < n. Then A can be factored as $A = B^*B$ with $B \in \mathbb{C}^{r\times n}$. If A is a real matrix, then B can be taken to be real and $A = B^TB$. Equivalently, there exist vectors $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n \in \mathbb{C}^r$ (or $\mathbb{R}^r$) such that $a_{ij} = \mathbf{v}_i^*\mathbf{v}_j$ (or $\mathbf{v}_i^T\mathbf{v}_j$). Note that A is the Gram matrix (see Section 9.1) of the vectors $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$. In particular, any rank 1 PSD matrix has the form $\mathbf{x}\mathbf{x}^*$ for some nonzero vector $\mathbf{x} \in \mathbb{C}^n$.
20. [Lax96, p. 123]; see also [HJ13, p. 441] The Gram matrix G of a set of vectors $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$ is PSD. If $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$ are linearly independent, then G is PD.
21. [HJ13, p. 449] *Polar Form:* Let $A \in \mathbb{C}^{m\times n}, m \geq n$. Then A can be factored $A = UP$, where $P \in \mathrm{PSD}_n$, and $U \in \mathbb{C}^{m\times n}$ has orthonormal columns. Moreover, P is uniquely determined by A and equals $(A^*A)^{1/2}$. If A is real, then P and U may be taken to be real. (See also Section 24.1.)
22. Any matrix $A \in \mathrm{PD}_n$ is diagonally congruent to a correlation matrix via the diagonal matrix $D = (1/\sqrt{a_{11}}, \dots, 1/\sqrt{a_{nn}})$.
23. [BJT93] *Parameterization of Correlation Matrices in $\mathcal{S}_3$:* Let $0 \leq \alpha, \beta, \gamma \leq \pi$. Then the matrix
$$C = \begin{bmatrix} 1 & \cos\alpha & \cos\gamma \\ \cos\alpha & 1 & \cos\beta \\ \cos\gamma & \cos\beta & 1 \end{bmatrix}$$
is PSD if and only if $\alpha \leq \beta + \gamma, \quad \beta \leq \alpha + \gamma, \quad \gamma \leq \alpha + \beta, \quad \alpha + \beta + \gamma \leq 2\pi$. Furthermore, C is PD if and only if all of these inequalities are strict.
24. [HJ13, p. 495] and [Fie86, p. 55] Let $A = \begin{bmatrix} B & C \\ C^* & D \end{bmatrix} \in \mathcal{H}_n$, and assume that B is invertible. Then A is PD if and only if the matrices B and its Schur complement $S = D - C^*B^{-1}C$ are PD.
25. [Joh92] and [LB96, pp. 93–94] Let $A = \begin{bmatrix} B & C \\ C^* & D \end{bmatrix}$ be PSD. Then any column of C lies in the span of the columns of B.
26. [HJ13, p. 486] Let $A \in \mathrm{PD}_n$ and $B \in \mathcal{H}_n$. Then AB is diagonalizable and all eigenvalues of AB are real.
27. Any diagonalizable matrix A with real eigenvalues can be factored as $A = BC$, where B is PSD and C is Hermitian.
28. If $A, B \in \mathrm{PD}_n$, then every eigenvalue of AB is positive.
29. [Lax96, p. 120] and [Bha07, p. 8] Let $A, B \in \mathcal{H}_n$. If A is PD and $AB + BA$ is PD, then B is PD. It is not true that if A, B are both PD, then $AB + BA$ is PD as can be seen by the example $A = \begin{bmatrix} 1 & 2 \\ 2 & 5 \end{bmatrix}, \ B = \begin{bmatrix} 5 & 2 \\ 2 & 1 \end{bmatrix}$.
30. [HJ13, p. 488] and [Lax96, pp. 125–126] The real valued function $f(X) = \log(\det X)$ is concave on the set PD_n; i.e., $f((1-t)X + tY) \geq (1-t)f(X) + tf(Y)$ for all $t \in [0, 1]$ and all $X, Y \in PD_n$ with equality if and only if $X = Y$.
31. [Lax96, p. 129] If $A \in \mathrm{PD}_n$ is real, $\displaystyle\int_{\mathbb{R}^n} e^{-\mathbf{x}^TA\mathbf{x}}\, d\mathbf{x} = \frac{\pi^{n/2}}{\sqrt{\det A}}$.
32. [Fie60] Let $A = [a_{ij}], \ B = [b_{ij}] \in \mathrm{PD}_n$, with $A^{-1} = [\alpha_{ij}], \ B^{-1} = [\beta_{ij}]$. Then
$$\sum_{i,j=1}^{n} (a_{ij} - b_{ij})(\alpha_{ij} - \beta_{ij}) \leq 0,$$
with equality if and only if $A = B$.
33. [Ber73, p. 55] Consider PD_n to be a subset of $\mathbb{C}^{n^2}$ (or for real matrices of $\mathbb{R}^{n^2}$). Then the (topological) boundary of PD_n is PSD_n.

Examples:

1. If $A = [a]$ is 1×1, then A is PD if and only if $a > 0$, and is PSD if and only if $a \geq 0$; so PD and PSD matrices are a generalization of positive numbers and nonnegative numbers.
2. If one attempts to define PD (or PSD) for nonsymmetric real matrices according to the usual definition, many of the previous facts for (Hermitian) PD matrices no longer hold. For example, suppose $A = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$. Then $\mathbf{x}^T A\mathbf{x} = 0$ for all $\mathbf{x} \in \mathbb{R}^2$. But $\sigma(A) = \{i, -i\}$, which does not agree with Fact 4.
3. The matrix $A = \begin{bmatrix} 17 & 8 \\ 8 & 17 \end{bmatrix}$ factors as $\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} 25 & 0 \\ 0 & 9 \end{bmatrix} \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$, so $A^{1/2} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} 5 & 0 \\ 0 & 3 \end{bmatrix} \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} = \begin{bmatrix} 4 & 1 \\ 1 & 4 \end{bmatrix}$.
4. Let $X_1, X_2, \ldots, X_n$ be real-valued random variables on a probability space, each with mean zero and finite second moment. Define the matrix

   $$a_{ij} = E(X_i X_j), \quad i, j \in \{1, 2, \ldots, n\}.$$

   The real symmetric matrix A is called the *covariance matrix* of $X_1, X_2, \ldots, X_n$, and is necessarily PSD. If we let $X = (X_1, X_2, \ldots, X_n)^T$, then we may abbreviate the definition to $A = E(XX^T)$.

Applications:

1. [HFKLMO95, p. 181] or [MT88, p. 253] *Test for Maxima and Minima in Several Variables:* Let D be an open set in $\mathbb{R}^n$ containing the point $\mathbf{x}_0$, let $f : D \to \mathbb{R}$ be a twice continuously differentiable function on D, and assume that all first derivatives of f vanish at $\mathbf{x}_0$. Let H be the Hessian matrix of f (Example 2 of Section 9.1). Then

   (a) f has a relative minimum at $\mathbf{x}_0$ if $H(\mathbf{x}_0)$ is PD.
   (b) f has a relative maximum at $\mathbf{x}_0$ if $-H(\mathbf{x}_0)$ is PD.
   (c) f has a saddle point at $\mathbf{x}_0$ if $H(\mathbf{x}_0)$ is indefinite.

   Otherwise, the test is inconclusive.
2. Section 1.3 of the textbook [Str86] is an elementary introduction to real PD matrices emphasizing the significance of the Cholesky-like factorization LDL^T of a PD matrix. This representation is then used as a framework for many applications throughout the first three chapters of this text.
3. Let A be a real matrix in PD_n. A *multivariate normal distribution* is one whose probability density function in $\mathbb{R}^n$ is given by

   $$f(\mathbf{x}) = \frac{1}{\sqrt{(2\pi)^n \det A}} e^{-\frac{1}{2}\mathbf{x}^T A^{-1}\mathbf{x}}.$$

   It follows from Fact 31 that $\int_{\mathbb{R}^n} f(\mathbf{x})\, d\mathbf{x} = 1$. A *Gaussian family* $X_1, X_2, \ldots X_n$, where each X_i has mean zero, is a set of random variables that have a multivariate normal distribution. The entries of the matrix A satisfy the identity $a_{ij} = E(X_i X_j)$, so the distribution is completely determined by its covariance matrix.

9.5 Further Topics in Positive Definite Matrices

Definitions:

Let $A, B \in F^{n\times n}$, where F is a field. The **Hadamard product** or **Schur product** of A and B, denoted $A \circ B$, is the matrix in $F^{n\times n}$ whose $(i, j)^{th}$ entry is $a_{ij}b_{ij}$.

A function $f : \mathbb{R} \to \mathbb{C}$ is called **positive semidefinite** if for each $n \in \mathbb{N}$ and all $x_1, x_2, \dots, x_n \in \mathbb{R}$, the $n \times n$ matrix $[f(x_i - x_j)]$ is PSD.

Let $A, B \in \mathcal{H}_n$. We write $A \succ B$ if $A - B$ is PD, and $A \succeq B$ if $A - B$ is PSD. The partial ordering on $\mathcal{H}_n$ induced by $\succeq$ is called the **partial semidefinite ordering** or the **Loewner ordering**.

Let V be an n-dimensional inner product space over $\mathbb{C}$ or $\mathbb{R}$. A set $K \subseteq V$ is called a **cone** if

(a) For each $\mathbf{x}, \mathbf{y} \in K$, $\mathbf{x} + \mathbf{y} \in K$.
(b) If $\mathbf{x} \in K$ and $c \geq 0$, then $c\mathbf{x} \in K$.

A cone is frequently referred to as a convex cone.

A cone K is **closed** if K is a closed subset of V, is **pointed** if $K \cap -K = \{0\}$, and is **full** if it has a nonempty interior.

The set

$$K^* = \{\mathbf{y} \in V \mid \langle \mathbf{x}, \mathbf{y}\rangle \geq 0 \quad \forall\, \mathbf{x} \in K\}$$

is called the **dual space**.

Facts:

1. [HJ13, p. 479] or [Lax96, pp. 124, 234] *Schur Product Theorem:* If A, B are PSD, then so is $A \circ B$. If A is PD and B is PSD with $b_{ii} > 0$, $i = 1, \dots, n$, then $A \circ B$ is PD. In particular, if A and B are both PD, then so is $A \circ B$.
2. [HJ13, p. 480] *Moutard's Theorem:* Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$. Then A is PSD if and only if

$$\sum_{i,j=1}^{n} a_{ij}\, b_{ij} \geq 0$$

for every $B \in \mathrm{PSD}_n$.
3. [HJ91, pp. 245–246] If $A \in \mathrm{PD}_m$ and $B \in \mathrm{PD}_n$, then the Kronecker (tensor) product (see Section 11.4) $A \otimes B \in \mathrm{PD}_{mn}$. If $A \in \mathrm{PSD}_m$ and $B \in \mathrm{PSD}_n$, then $A \otimes B \in \mathrm{PSD}_{mn}$.
4. [HJ13, p. 505] or [Lax96, pp. 126–127, 131–132] *Hadamard's Determinantal Inequality:* If $A \in \mathrm{PD}_n$, then $\det A \leq \prod_{i=1}^{n} a_{ii}$. Equality holds if and only if A is a diagonal matrix.
5. [FJ00, pp. 199–200] or [HJ13, p. 506] *Fischer's Determinantal Inequality:* If $A \in \mathrm{PD}_n$ and α is any subset of $\{1, 2, \dots, n\}$, then $\det A \leq \det A[\alpha] \det A[\alpha^c]$ (where $\det A[\emptyset] = 1$). Equality occurs if and only if $A[\alpha, \alpha^c]$ is a zero matrix. (See Section 1.2 for the definition of $A[\alpha]$ and $A[\alpha, \beta]$.)
6. [FJ00, pp. 199–200] or [HJ13, p. 507] *Koteljanskii's Determinantal Inequality:* Let $A \in \mathrm{PD}_n$ and let α, β be any subsets of $\{1, 2, \dots, n\}$. Then $\det A[\alpha \cup \beta] \det A[\alpha \cap \beta] \leq \det A[\alpha] \det A[\beta]$. Note that if $\alpha \cap \beta = \emptyset$, Koteljanskii's inequality reduces to Fischer's inequality. Koteljanskii's inequality is also called the Hadamard–Fischer inequality. For other determinantal inequalities for PD matrices, see [FJ00] and [HJ13, Sect. 7.8].
7. [Bha07, pp. 169–172] and [Fel71, pp. 620–623] *Bochner's Theorem:* The Fourier transform of a finite positive measure is a positive semidefinite function; moreover, any positive semidefinite function which is continuous at 0 is the Fourier transform of a finite positive measure.
8. [Lax96, p. 118] Let $A, B, C, D \in \mathcal{H}_n$.

   (a) If $A \prec B$ and $C \prec D$, then $A + C \prec B + D$.

   (b) If $A \prec B$ and $B \prec C$, then $A \prec C$.
   (c) If $A \prec B$ and $S \in \mathbb{C}^{n\times n}$ is invertible, then $S^*AS \prec S^*BS$.

   The three statements obtained by replacing each occurrence of $\prec$ by $\preceq$ are also valid.

9. [Lax96, pp. 118–119, 121–122] and [HJ13, p. 495] Let $A, B \in \mathrm{PD}_n$ with $A \prec B$. Then
   (a) $A^{-1} \succ B^{-1}$.
   (b) $A^{1/2} \prec B^{1/2}$.
   (c) $\det A < \det B$.
   (d) tr $A <$ tr B.

   If $A \preceq B$, then statement (a) holds with $\succ$ replaced by $\succeq$, statement (b) holds with $\prec$ replaced by $\preceq$, and statements (c) and (d) hold with $<$ replaced by $\leq$.
10. [HJ13, p. 495] Let $A, B \in \mathcal{H}_n$ with eigenvalues $\lambda_1(A) \geq \lambda_2(A) \geq \cdots \geq \lambda_n(A)$ and $\lambda_1(B) \geq \lambda_2(B) \geq \cdots \geq \lambda_n(B)$. If $A \prec B$, then $\lambda_k(A) < \lambda_k(B)$, $k = 1, \ldots, n$. If $A \preceq B$, then $\lambda_k(A) \leq \lambda_k(B)$, $k = 1, \ldots, n$.
11. [HJ13, p. 499] Let A be PD and let $\alpha \subseteq \{1, 2, \ldots, n\}$. Then $A^{-1}[\alpha] \succeq (A[\alpha])^{-1}$.
12. [HJ13, p. 500] If A is PD, then $A^{-1} \circ A \succeq I \succeq (A^{-1} \circ A)^{-1}$.
13. [Hal83, p. 89] If K is a cone in an inner product space V, its dual space is a closed cone and is called the **dual cone** of K. If K is a closed cone, then $(K^*)^* = K$.
14. [Ber73, pp. 49–50, 55] and [HW87, p. 82] For each pair $A, B \in \mathcal{H}_n$, define $\langle A, B\rangle =$ tr (AB).
   (a) $\mathcal{H}_n$ is an inner product space over the real numbers with respect to $\langle\cdot,\cdot\rangle$.
   (b) PSD_n is a closed, pointed, full cone in $\mathcal{H}_n$.
   (c) $(\mathrm{PSD}_n)^* = \mathrm{PSD}_n$.

Examples:

1. The matrix $C = [\cos|i-j|] \in \mathcal{S}_n$ is PSD, as can be verified with Fact 9.4.19 and the addition formula for the cosine. But a quick way to see it is to consider the measure $\mu(x) = \frac{1}{2}[\delta(x+1) + \delta(x-1)]$; i.e., $\mu(E) = 0$ if $-1, 1 \notin E$, $\mu(E) = 1$ if $-1, 1 \in E$, and $\mu(E) = 1/2$ if exactly one of $-1, 1 \in E$. Since the Fourier transform of μ is $\cos t$, if we let $x_1, x_2, \ldots, x_n$ be $1, 2, \ldots, n$ in the definition of positive definite function, we see immediately by Bochner's Theorem that the matrix $[\cos(i-j)] = [\cos|i-j|] = C$ is PSD. By Hadamard's determinantal inequality $\det C \leq \prod_{i=1}^n c_{ii} = 1$.
2. Since $\begin{bmatrix} 1 & 1 \\ 1 & 2 \end{bmatrix} \prec \begin{bmatrix} 2 & 2 \\ 2 & 7 \end{bmatrix}$, taking inverses we have $\begin{bmatrix} .7 & -.2 \\ -.2 & .2 \end{bmatrix} \prec \begin{bmatrix} 2 & -1 \\ -1 & 1 \end{bmatrix}$.
3. The matrix $A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 2 & 2 \\ 1 & 2 & 3 \end{bmatrix}$ is *PD* with inverse $A^{-1} = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 1 \end{bmatrix}$. Then $(A[\{1,3\}])^{-1} = \begin{bmatrix} 1.5 & -.5 \\ -.5 & .5 \end{bmatrix} \preceq \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix} = A^{-1}[\{1,3\}]$.

   Also, $A^{-1} \circ A = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 4 & -2 \\ 0 & -2 & 3 \end{bmatrix} \succeq \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \succeq \frac{1}{13}\begin{bmatrix} 8 & 3 & 2 \\ 3 & 6 & 4 \\ 2 & 4 & 7 \end{bmatrix} = (A^{-1} \circ A)^{-1}$.
4. If $A \succeq B \succeq 0$, it does not follow that $A^2 \succeq B^2$. For example, if $A = \begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}$ and $B = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$, then B and $A - B$ are PSD, but $A^2 - B^2$ is not.

Applications:

1. Hadamard's determinantal inequality can be used to obtain a sharp bound on the determinant of a matrix in $\mathbb{C}^{n\times n}$ if only the magnitudes of the entries are known. [HJ13, p. 506] or [Lax96, p. 127].

   Hadamard's Determinantal Inequality for Matrices in $\mathbb{C}^{n\times n}$*:*
   Let $B \in \mathbb{C}^{n\times n}$. Then $|\det B| \le \prod_{i=1}^{n}(\sum_{j=1}^{n}|b_{ij}|^2)^{1/2}$ with equality holding if and only if the rows of B are orthogonal.

   In the case that B is invertible, the inequality follows from Hadamard's determinantal inequality for positive definite matrices by using $A = BB^*$; if B is singular, the inequality is obvious.

   The inequality can be alternatively expressed as $|\det B| \le \prod_{i=1}^{n}\|\mathbf{b}_i\|_2$, where $\mathbf{b}_i$ are the rows of B. If B is a real matrix, it has the geometric meaning that among all parallelepipeds with given side lengths $\|\mathbf{b}_i\|_2,\ i = 1,\ldots,n$, the one with the largest volume is rectangular.

   There is a corresponding inequality in which the right-hand side is the product of the lengths of the columns of B.
2. [Fel71, pp. 620–623] A special case of Bochner's theorem, important in probability theory, is: A continuous function ϕ is the characteristic function of a probability distribution if and only if it is positive semidefinite and $\phi(0) = 1$.
3. Understanding the cone PSD_n is important in semidefinite programming. (See Chapter 69.)

Uriel G. Rothblum
Technion

Nonnegativity is a natural property of many measured quantities (physical and virtual). Consequently, nonnegative matrices arise in modelling transformations in numerous branches of science and engineering — these include probability theory (Markov chains), population models, iterative methods in numerical analysis, economics (input–output models), epidemiology, statistical mechanics, stability analysis, and physics. This chapter is concerned with properties of such matrices. The theory of the subject was originated in the pioneering work of Perron and Frobenius in [Per07a, Per07b, Fro08, Fro09, and Fro12]. There have been books, chapters in books, and hundreds of papers on the subject (e.g., [BNS89], [BP94], [Gan59, Chap. XIII], [Har02] [HJ85, Chap. 8], [LT85, Chap. 15], [Min88], [Sen81], [Var62, Chap. 1]). A brief outline of proofs of the classic result of Perron and a description of several applications of the theory can be found in the survey paper [Mac00]. Generalizations of many facts reported herein to cone-invariant matrices can be found in Chapter 36.

10.1 Notation, Terminology, and Preliminaries

Definitions:

For a positive integer n, $\langle n\rangle = \{1, \dots, n\}$.

For a matrix $A \in \mathbb{C}^{m\times n}$:

A is **nonnegative (positive)**, written $A \geq 0$ ($A > 0$), if all of A's elements are nonnegative (positive).

A is **semipositive**, written $A \gneq 0$ if $A \geq 0$ and $A \neq 0$.

$|A|$ will denote the nonnegative matrix obtained by taking element-wise absolute values of A's coordinates.

For a square matrix $A = [a_{ij}] \in \mathbb{C}^{n\times n}$:

The k-**eigenspace** of A at a complex number λ, denoted $N_\lambda^k(A)$, is $\ker(A-\lambda I)^k$; a **generalized eigenvector** of P at λ is a vector in $\cup_{k=0}^{\infty} N_\lambda^k(A)$.

The **index** of A at λ, denoted $\nu_A(\lambda)$, is the smallest integer k with $N_\lambda^k(A) = N_\lambda^{k+1}(A)$.

The **ergodicity coefficient of** A, denoted $\tau(A)$, is $\max\{|\lambda| : \lambda \in \sigma(A)$ and $|\lambda| \neq \rho(A)\}$ (with the maximum over the empty set defined to be 0 and $\rho(A)$ being the spectral radius of A).

A **group inverse** of a square matrix A, denoted $A^{\#}$, is a matrix X satisfying $AXA = A$, $XAX = X$, and $AX = XA$ (whenever there exists such an X, it is unique).

The **digraph of** A, denoted $\Gamma(A)$, is the graph with vertex-set $V(A) = \langle n \rangle$ and arc-set $E(A) = \{(i,j) : i,j \in \langle n \rangle$ and $a_{ij} \neq 0\}$; in particular, $i = 1, \ldots, n$ are called **vertices**.

Vertex $i \in \langle n \rangle$ **has access to** vertex $j \in \langle n \rangle$, written $i \mapsto j$, if either $i = j$ or $\Gamma(A)$ contains a simple walk (path) from i to j; we say that i and j **communicate**, written $i \sim j$, if each has access to the other.

A subset C of $\langle n \rangle$ is **final** if no vertex in C has access to a vertex not in C.

Vertex-communication is an equivalence relation. It partitions $\langle n \rangle$ into equivalence classes, called the **access equivalence classes** of A.

$\Gamma(A)$ is **strongly connected** if there is only one access equivalence class.

An access equivalence class C **has access to** an access equivalence class C', written $C \mapsto C'$ if some, or equivalently every, vertex in C has access to some, or equivalently every, vertex in C'; in this case we also write $i \mapsto C'$ and $C \mapsto i'$ when $i \in C$ and $i' \in C'$.

An access equivalence class C of A is **final** if it is final as a subset of $\langle n \rangle$; that is, it does not have access to any access equivalence class but itself.

The **reduced digraph** of $\Gamma(A)$, denoted $R[\Gamma(A)]$, is the digraph whose vertex-set is the set of access equivalence classes of A and whose arcs are the pairs (C, C') with C and C' as distinct classes satisfying $C \mapsto C'$.

For a sequence $\{a_m\}_{m=0,1,\ldots}$ of complex numbers and a complex number a:

a is a $(C,0)$-**limit** of $\{a_m\}_{m=0,1,\ldots}$, written $\lim_{m\to\infty} a_m = a \ (C,0)$, if $\lim_{m\to\infty} a_m = a$ (in the sense of a regular limit).

a is the $(C,1)$-**limit** of $\{a_m\}_{m=0,1,\ldots}$, written $\lim_{m\to\infty} a_m = a \ (C,1)$, if $\lim_{m\to\infty} m^{-1} \sum_{s=0}^{m-1} a_s = a$.

Inductively for $k = 2, 3, \ldots$, a is a (C,k)-**limit** of $\{a_m\}_{m=0,1,\ldots}$, written $\lim_{m\to\infty} a_m = a \ (C,k)$, if $\lim_{m\to\infty} m^{-1} \sum_{s=0}^{m-1} a_s = a \ (C, k-1)$.

For $0 \leq \beta < 1$, $\{a_m\}_{m=0,1,\ldots}$ **converges geometrically to** a **with (geometric) rate** β if for each $\beta < \gamma < 1$, the set of real numbers $\{\frac{a_m - a}{\gamma^m} : m = 0, 1, \ldots\}$ is bounded. (For simplicity, we avoid the reference of geometric convergence for (C,k)-limits.)

For a square nonnegative matrix P:

$\rho(P)$ (the spectral radius of P) is called the **Perron value** of P (see Facts 10.2.1(b) and 10.2.5(a) and 10.3.2(a)).

A **distinguished eigenvalue** of P is a (necessarily nonnegative) eigenvalue of P that is associated with a semipositive (right) eigenvector.

For more information about generalized eigenvectors, see Section 6.1. An example illustrating the digraph definitions is given in Figure 10.1; additional information about digraphs can be found in Chapter 40.

10.2 Irreducible Matrices

See Section 38.3, Section 40.5, and Section 40.6 for additional information.

Definitions:

A nonnegative square matrix P is **irreducible** if it is not permutation similar to any matrix having the (nontrivial) block-partition

$$\begin{bmatrix} A & B \\ 0 & C \end{bmatrix}$$

with A and C square.

The **period** of an irreducible nonnegative square matrix P (also known as the **index of imprimitivity** of P) is the greatest common divisor of lengths of the cycles of $\Gamma(P)$, the digraph of P.

An irreducible nonnegative square matrix P is **aperiodic** if its period is 1.

Note: We exclude from further consideration the (irreducible) trivial 0 matrix of dimension 1×1.

Facts:

Facts requiring proofs for which no specific reference is given can be found in [BP94, Chap. 2].

1. (*Positive Matrices — Perron's Theorem*) [Per07a, Per07b] Let P be a positive square matrix with spectral radius ρ and ergodicity coefficient τ.
   (a) P is irreducible and aperiodic.
   (b) ρ is positive and is a simple eigenvalue of P; in particular, the index of P at ρ is 1.
   (c) There exist positive right and left eigenvectors of P corresponding to ρ, in particular, ρ is a distinguished eigenvalue of both P and P^T.
   (d) ρ is the only distinguished eigenvalue of P.
   (e) ρ is the only eigenvalue λ of P with $|\lambda| = \rho$.
   (f) If $\mathbf{x} \in \mathbb{R}^n$ satisfies $\mathbf{x} \geq 0$ and either $(\rho I - P)\mathbf{x} \geq 0$ or $(\rho I - P)\mathbf{x} \leq 0$, then $(\rho I - P)\mathbf{x} = 0$.
   (g) If $\mathbf{v}$ and $\mathbf{w}$ are positive right and left eigenvectors of P corresponding to ρ (note that $\mathbf{w}$ is a row vector), then $\lim_{m\to\infty}(\frac{P}{\rho})^m = \frac{\mathbf{vw}}{\mathbf{wv}}$ and the convergence is geometric with rate $\frac{\tau}{\rho}$.
   (h) $Q \equiv \rho I - P$ has a group inverse; further, if $\mathbf{v}$ and $\mathbf{w}$ are positive right and left eigenvectors of P corresponding to ρ, then $Q + \frac{\mathbf{vw}}{\mathbf{wv}}$ is nonsingular, $Q^{\#} = (Q + \frac{\mathbf{vw}}{\mathbf{wv}})^{-1}(I - \frac{\mathbf{vw}}{\mathbf{wv}})$, and $\frac{\mathbf{vw}}{\mathbf{wv}} = I - QQ^{\#}$.
   (i) $\lim_{m\to\infty} \sum_{t=0}^{m-1} (\frac{P}{\rho})^t - m\frac{\mathbf{vw}}{\mathbf{wv}} = (\rho I - P)^{\#}$ and the convergence is geometric with rate $\frac{\tau}{\rho}$.
2. (*Characterizing Irreducibility*) Let P be a nonnegative $n \times n$ matrix with spectral radius ρ. The following are equivalent:
   (a) P is irreducible.
   (b) $\sum_{s=0}^{n-1} P^s > 0$.
   (c) $(I + P)^{n-1} > 0$.
   (d) The digraph of P is strongly connected, i.e., P has a single access equivalence class.
   (e) Every eigenvector of P corresponding to ρ is a scalar multiple of a positive vector.
   (f) For some $\mu > \rho$, $\mu I - P$ is nonsingular and $(\mu I - P)^{-1} > 0$.
   (g) For every $\mu > \rho$, $\mu I - P$ is nonsingular and $(\mu I - P)^{-1} > 0$.
3. (*Characterizing Aperiodicity*) Let P be an irreducible nonnegative $n \times n$ matrix. The following are equivalent:
   (a) P is aperiodic.

   (b) $P^m > 0$ for some m.
   (c) $P^m > 0$ for all $m \geq n^2 - 2n + 2$.
   (d) $P^{n^2-2n+2} > 0$.

4. (*The Period*) Let P be an irreducible nonnegative $n \times n$ matrix with period q.
   (a) q is the greatest common divisor of $\{m : m$ is a positive integer and $(P^m)_{ii} > 0\}$ for any one, or equivalently all, $i \in \{1, \ldots, n\}$.
   (b) There exists a partition $C_1, \ldots, C_q$ of $\{1, \ldots, n\}$ such that:
      i. For $s, t = 1, \ldots, q$, $P[C_s, C_t] \neq 0$ if and only if $t = s + 1$ (with $q + 1$ identified with 1); in particular, P is permutation similar to a block rectangular matrix having a representation

$$\begin{bmatrix} 0 & P[C_1, C_2] & 0 & \ldots & 0 \\ 0 & 0 & P[C_2, C_3] & \ldots & 0 \\ \vdots & \vdots & \vdots & \ldots & \vdots \\ 0 & 0 & 0 & \ldots & P[C_{q-1}, C_q] \\ P[C_q, C_1] & 0 & 0 & \ldots & 0 \end{bmatrix}.$$

      ii. $P^q[C_s]$ is irreducible for $s = 1, \ldots, q$ and $P^q[C_s, C_t] = 0$ for $s, t = 1, \ldots, n$ with $s \neq t$; in particular, P^q is permutation similar to a block diagonal matrix having irreducible blocks on the diagonal.

5. (*Spectral Properties — The Perron–Frobenius Theorem*) [Fro12] Let P be an irreducible nonnegative square matrix with spectral radius ρ and period q.
   (a) ρ is positive and is a simple eigenvalue of P; in particular, the index of P at ρ is 1.
   (b) There exist positive right and left eigenvectors of P corresponding to ρ; in particular, ρ is a distinguished eigenvalue of both P and P^T.
   (c) ρ is the only distinguished eigenvalue of P and of P^T.
   (d) If $\mathbf{x} \in \mathbb{R}^n$ satisfies $\mathbf{x} \geq 0$ and either $(\rho I - P)\mathbf{x} \geq 0$ or $(\rho I - P)\mathbf{x} \leq 0$, then $(\rho I - P)\mathbf{x} = 0$.
   (e) The eigenvalues of P with modulus ρ are $\{\rho e^{(2\pi i)k/q} : k = 0, \ldots, q-1\}$ (here, i is the complex root of -1) and each of these eigenvalues is simple. In particular, if P is aperiodic ($q = 1$), then every eigenvalue $\lambda \neq \rho$ of P satisfies $|\lambda| < \rho$.
   (f) The multiset of eigenvalues is invariant under multiplication by $e^{(2\pi i)k/q}$.
   (g) $Q \equiv \rho I - P$ has a group inverse; further, if $\mathbf{v}$ and $\mathbf{w}$ are positive right and left eigenvectors of P corresponding to ρ, then $Q + \frac{\mathbf{vw}}{\mathbf{wv}}$ is nonsingular, $Q^{\#} = (Q + \frac{\mathbf{vw}}{\mathbf{wv}})^{-1}(I - \frac{\mathbf{vw}}{\mathbf{wv}})$, and $\frac{\mathbf{vw}}{\mathbf{wv}} = I - QQ^{\#}$.

6. (*Convergence Properties of Powers*) Let P be an irreducible nonnegative square matrix with spectral radius ρ, index ν, period q, and ergodicity coefficient τ. Also, let $\mathbf{v}$ and $\mathbf{w}$ be positive right and left eigenvectors of P corresponding to ρ and let $P^\star \equiv \frac{\mathbf{vw}}{\mathbf{wv}}$.
   (a) $\lim_{m\to\infty}(\frac{P}{\rho})^m = P^\star$ (C,1).
   (b) $\lim_{m\to\infty} \frac{1}{q}\sum_{t=m}^{m+q-1}(\frac{P}{\rho})^t = P^\star$ and the convergence is geometric with rate $\frac{\tau}{\rho} < 1$. In particular, if P is aperiodic ($q = 1$), then $\lim_{m\to\infty}(\frac{P}{\rho})^m = P^\star$ and the convergence is geometric with rate $\frac{\tau}{\rho} < 1$.
   (c) For each $k = 0, \ldots, q-1$, $\lim_{m\to\infty}(\frac{P}{\rho})^{mq+k}$ exists and the convergence of these sequences to their limit is geometric with rate $(\frac{\tau}{\rho})^q < 1$.
   (d) $\lim_{m\to\infty}\sum_{t=0}^{m-1}(\frac{P}{\rho})^t - mP^\star = (I - \rho^{-1}P)^{\#}$ (C,1); further, if P is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate $\frac{\tau}{\rho} < 1$.

7. (*Bounds on the Perron Value*) Let P be an irreducible nonnegative $n \times n$ matrix with spectral radius ρ, let μ be a nonnegative scalar, and let $\diamond \in \{<, \lneq, \leq, =, \geq, \gneq, >\}$. The following are equivalent:
   (a) $\rho \diamond \mu$.
   (b) There exists a vector $\mathbf{u} \gneq 0$ in $\mathbb{R}^n$ with $P\mathbf{u} \diamond \mu\mathbf{u}$.
   (c) There exists a vector $\mathbf{u} > 0$ in $\mathbb{R}^n$ with $P\mathbf{u} \diamond \mu\mathbf{u}$.

   In particular,
$$\rho = \max_{\mathbf{x} \gneq 0} \min_{\{i : x_i > 0\}} \frac{(P\mathbf{x})_i}{x_i} = \min_{\mathbf{x} \gneq 0} \max_{\{i : x_i > 0\}} \frac{(P\mathbf{x})_i}{x_i}$$
$$= \max_{\mathbf{x} > 0} \min_{i} \frac{(P\mathbf{x})_i}{x_i} = \min_{\mathbf{x} > 0} \max_{i} \frac{(P\mathbf{x})_i}{x_i}.$$
   Since $\rho(P^T) = \rho(P)$, the above properties (and characterizations) of ρ can be expressed by applying the above conditions to P^T.

   Consider the sets $\Omega(P) \equiv \{\mu \geq 0 : \exists \mathbf{x} \gneq 0, P\mathbf{x} \geq \mu\mathbf{x}\}$, $\Omega_1(P) \equiv \{\mu \geq 0 : \exists \mathbf{x} > 0,\ P\mathbf{x} \geq \mu\mathbf{x}\}, \Sigma(P) \equiv \{\mu \geq 0 : \exists \mathbf{x} \gneq 0, P\mathbf{x} \leq \mu\mathbf{x}\}$, $\Sigma_1(P) \equiv \{\mu \geq 0 : \exists \mathbf{x} > 0, P\mathbf{x} \leq \mu\mathbf{x}\}$; these sets were named the Collatz–Wielandt sets in [BS75], giving credit to ideas used in [Col42], [Wie50]. The above properties (and characterizations) of ρ can be expressed through maximal/minimal elements of the Collatz–Wielandt sets of P and P^T. (For further details see Chapter 36.)
8. (*Bounds on the Spectral Radius*) Let A be a complex $n \times n$ matrix and let P be an irreducible nonnegative $n \times n$ matrix such that $|A| \leq P$.
   (a) $\rho(A) \leq \rho(P)$.
   (b) [Wie50], [Sch96] $\rho(A) = \rho(P)$ if and only if there exist a complex number μ with $|\mu| = 1$ and a complex diagonal matrix D with $|D| = I$ such that $A = \mu D^{-1} P D$; in particular, in this case $|A| = P$.
   (c) If A is real and μ and $\diamond \in \{<, \lneq\}$ satisfy the condition stated in Fact 7b or 7c, then $\rho(A) < \mu$.
   (d) If A is real and μ and $\diamond \in \{\leq, =\}$ satisfy the condition stated in Fact 7b or 7c, then $\rho(A) \leq \mu$.
9. (*Functional Inequalities*) Consider the function $\rho(.)$ mapping irreducible, nonnegative $n \times n$ matrices to their spectral radius.
   (a) $\rho(.)$ is strictly increasing in each element (of the domain matrices), i.e., if A and B are irreducible, nonnegative $n \times n$ matrices with $A \gneq B \geq 0$, then $\rho(A) > \rho(B)$.
   (b) [Coh78] $\rho(.)$ is (jointly) convex in the diagonal elements, i.e., if A and D are $n \times n$ matrices, with D diagonal, A and $A + D$ nonnegative and irreducible and if $0 < \alpha < 1$, then $\rho[\alpha A + (1 - \alpha)(A + D)] \leq \alpha\rho(A) + (1 - \alpha)\rho(A + D)$.

   For further functional inequalities that concern the spectral radius see Fact 10.3.8.
10. (*Taylor Expansion of the Perron Value*) [HRR92] The function $\rho(.)$ mapping irreducible nonnegative $n \times n$ matrices $X = [x_{ij}]$ to their spectral radius is differentiable of all orders and has a converging Taylor expansion. In particular, if P is an irreducible nonnegative $n \times n$ matrix with spectral radius ρ and corresponding positive right and left eigenvectors $\mathbf{v} = [v_i]$ and $\mathbf{w} = [w_j]$, normalized so that $\mathbf{wv} = 1$, and if F is an $n \times n$ matrix with $P + \epsilon F \geq 0$ for all sufficiently small positive ϵ, then $\rho(P + \epsilon F) = \sum_{k=0}^{\infty} \rho_k \epsilon^k$ with $\rho_0 = \rho, \rho_1 = \mathbf{w}F\mathbf{v}, \rho_2 = \mathbf{w}F(\rho I - P)^{\#}F\mathbf{v}, \rho_3 = \mathbf{w}F(\rho I - P)^{\#}(\mathbf{w}F\mathbf{v}I - F)(\rho I - P)^{\#}F\mathbf{v}$; in particular, $\frac{\partial\rho(X)}{\partial x_{ij}}|_{X=P} = w_i v_j$.

   An algorithm that iteratively generates all coefficients of the above Taylor expansion is available; see [HRR92].

11. (*Bounds on the Ergodicity Coefficient*) [RT85] Let P be an irreducible nonnegative $n \times n$ matrix with spectral radius ρ, corresponding positive right eigenvector $\mathbf{v}$, and ergodicity coefficient τ; let D be a diagonal $n \times n$ matrix with positive diagonal elements; and let $\|.\|$ be a norm on $\mathbb{R}^n$. Then

$$\tau \leq \max_{\mathbf{x}\in\mathbb{R}^n, \|\mathbf{x}\|\leq 1, \mathbf{x}^T D^{-1}\mathbf{v}=0} \|\mathbf{x}^T D^{-1} P D\|.$$

Examples:

1. We illustrate Fact 1 using the matrix

$$P = \begin{bmatrix} \frac{1}{2} & \frac{1}{6} & \frac{1}{3} \\ \frac{1}{4} & \frac{1}{4} & \frac{1}{2} \\ \frac{3}{4} & \frac{1}{8} & \frac{1}{8} \end{bmatrix}.$$

The eigenvalues of P are $1, \frac{1}{48}\left(-3-\sqrt{33}\right), \frac{1}{48}\left(-3+\sqrt{33}\right)$, so $\rho(A) = 1$. Also, $\mathbf{v} = [1,1,1]^T$ and $\mathbf{w} = [57, 18, 32]$ are positive right and left eigenvectors, respectively, corresponding to eigenvalue 1 and

$$\frac{\mathbf{vw}}{\mathbf{wv}} = \begin{bmatrix} \frac{57}{107} & \frac{18}{107} & \frac{32}{107} \\ \frac{57}{107} & \frac{18}{107} & \frac{32}{107} \\ \frac{57}{107} & \frac{18}{107} & \frac{32}{107} \end{bmatrix}.$$

2. We illustrate Fact 4 using the matrix

$$P = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}.$$

$\Gamma(P)$ has a 2-cycle and a 3-cycle, so the period of $\Gamma(P)$ is 1, i.e., P is aperiodic. Observe that $n = 3$, $n^2 - 2n + 2 = 5$, $P^4 = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 1 & 1 \\ 1 & 1 & 0 \end{bmatrix} \not> 0$ and $P^5 = \begin{bmatrix} 2 & 1 & 1 \\ 2 & 2 & 1 \\ 1 & 1 & 1 \end{bmatrix} > 0$.

3. We illustrate parts of Facts 5 and 6 using the matrix

$$P \equiv \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

The spectral radius of P is 1 with corresponding right and left eigenvectors $\mathbf{v} = (1,1)^T$ and $\mathbf{w} = (1,1)$, respectively, the period of P is 2, and $(I-P)^{\#} = \frac{I-P}{4}$. Evidently,

$$P^m = \begin{cases} I & \text{if } m \text{ is even} \\ P & \text{if } m \text{ is odd}. \end{cases}$$

In particular,

$$\lim_{m\to\infty} P^{2m} = I \quad \text{and} \quad \lim_{m\to\infty} P^{2m+1} = P$$

and

$$\frac{1}{2}[P^m + P^{m+1}] = \frac{I+P}{2} = \begin{bmatrix} .5 & .5 \\ .5 & .5 \end{bmatrix} = \mathbf{v}(\mathbf{wv})^{-1}\mathbf{w} \quad \text{for each } m = 0, 1, \ldots,$$

assuring that, trivially,

$$\lim_{m\to\infty} \frac{1}{2} \sum_{t=m}^{m+1} P^t = \begin{bmatrix} .5 & .5 \\ .5 & .5 \end{bmatrix} = \mathbf{v}(\mathbf{wv})^{-1}\mathbf{w}.$$

In this example, $\tau(P)$ is 0 (as the maximum over the empty set) and the convergence of the above sequences is geometric with rate 0. Finally,

$$\sum_{t=0}^{m-1} P^t = \begin{cases} \frac{m(I+P)}{2} & \text{if } m \text{ is even} \\ \frac{m(I+P)}{2} + \frac{I-P}{2} & \text{if } m \text{ is odd,} \end{cases}$$

implying that

$$\lim_{m\to\infty} P^m = \frac{(I+P)}{2} = \mathbf{v}(\mathbf{w}\mathbf{v})^{-1}\mathbf{w} \text{ (C,1)}$$

and

$$\lim_{m\to\infty} \sum_{t=0}^{m-1} P^t - m\left(\frac{I+P}{2}\right) = \frac{I-P}{4} \quad \text{(C,1)} .$$

4. We illustrate parts of Fact 10 using the matrix P of Example 2 and $F \equiv \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$. Then $\rho(P+\epsilon F) = \sqrt{1+\epsilon} = 1 + \frac{1}{2}\epsilon + \sum_{k=2}^{\infty} \epsilon^k \frac{(-1)^{k+1}}{k2^{2k-2}} \binom{2k-3}{k-2}$.
5. [RT85, Theorem 4.1] and [Hof67] With $\|.\|$ as the 1-norm on $\mathbb{R}^n$ and $d_1, \ldots, d_n$ as the (positive) diagonal elements of D, the bound in Fact 11 on the coefficient of ergodicity $\tau(P)$ of P becomes

$$\max_{r,s=1,\ldots,n, r\neq s} \frac{1}{d_s v_r + d_r v_s} \left(\sum_{k=1}^{n} d_k |v_s P_{rk} - v_r P_{sk}| \right) .$$

With $D = I$, a relaxation of this bound on $\tau(P)$ yields the expression

$$\leq \min \left\{ \rho - \sum_{j=1}^{n} \min_i \left(\frac{P_{ij} v_j}{v_i} \right), \sum_{j=1}^{n} \max_i \left(\frac{P_{ij} v_j}{v_i} \right) - \rho \right\} .$$

6. [RT85, Theorem 4.3] For a positive vector $\mathbf{u} \in \mathbb{R}^n$, consider the function $M^{\mathbf{u}} : \mathbb{R}^n \to \mathbb{R}$ defined for $\mathbf{a} \in \mathbb{R}^n$ by

$$M^{\mathbf{u}}(\mathbf{a}) = \max\{\mathbf{x}^T\mathbf{a} : \mathbf{x} \in \mathbb{R}^n, \|\mathbf{x}\| \leq 1, \mathbf{x}^T\mathbf{u} = 0\}.$$

This function has a simple explicit representation obtained by sorting the ratios $\frac{a_j}{u_j}$, i.e., identifying a permutation $j(1), \ldots, j(n)$ of $1, \ldots, n$ such that

$$\frac{a_{j(1)}}{u_{j(1)}} \leq \frac{a_{j(2)}}{u_{j(2)}} \leq \cdots \leq \frac{a_{j(n)}}{u_{j(n)}}.$$

With $k^\star$ as the smallest integer in $\{1, \ldots, n\}$ such that $2\sum_{p=1}^{k^\star} u_{j(p)} > \sum_{t=1}^{n} u_t$ and

$$\mu \equiv 1 + \left(\sum_{t=1}^{n} u_t - 2\sum_{p=1}^{k^\star} u_{j(p)} \right) ,$$

we have that

$$M^{\mathbf{u}}(\mathbf{a}) = \sum_{p=1}^{k^\star-1} a_{j(p)} + \mu a_{j(k^\star)} - \sum_{p=k^\star+1}^{n} a_{j(p)}.$$

With $\|.\|$ as the ∞-norm on $\mathbb{R}^n$ and $(D^{-1}PD)_1, \ldots, (D^{-1}PD)_n$ as the columns of $D^{-1}PD$, the bound in Fact 11 on the coefficient of ergodicity $\tau(P)$ of P becomes

$$\max_{r=1,\ldots,n} M^{D^{-1}\mathbf{w}}[(D^{-1}PD)_r].$$

10.3 Reducible Matrices

Definitions:

For a nonnegative $n \times n$ matrix P with spectral radius ρ:

A **basic class of** P is an access equivalence class B of P with $\rho(P[B]) = \rho$.

The **period** of an access equivalence class C of P (also known as the **index of imprimitivity** of C) is the period of the (irreducible) matrix $P[C]$.

The **period** of P (also known as the **index of imprimitivity** of P) is the least common multiple of the periods of its basic classes.

P is **aperiodic** if its period is 1.

The **index** of P, denoted ν_P, is $\nu_P(\rho)$.

The **co-index** of P, denoted $\bar{\nu}_P$, is $\max\{\nu_P(\lambda) : \lambda \in \sigma(P), |\lambda| = \rho \text{ and } \lambda \neq \rho\}$ (with the maximum over the empty set defined as 0).

The **basic reduced digraph** of P, denoted $R^*(P)$, is the digraph whose vertex-set is the set of basic classes of P and whose arcs are the pairs (B, B') of distinct basic classes of P for which there exists a simple walk in $R[\Gamma(P)]$ from B to B'.

The **height** of a basic class is the largest number of vertices on a simple walk in $R^*(P)$ which ends at B.

The **principal submatrix of** P at a distinguished eigenvalue λ, denoted $P[\lambda]$, is the principal submatrix of P corresponding to a set of vertices of $\Gamma(P)$ having no access to a vertex of an access equivalence class C that satisfies $\rho(P[C]) > \lambda$.

P is **convergent** or **transient** if $\lim_{m\to\infty} P^m = 0$.

P is **semiconvergent** if $\lim_{m\to\infty} P^m$ exists.

P is **weakly expanding** if $P\mathbf{u} \geq \mathbf{u}$ for some $\mathbf{u} > 0$.

P is **expanding** if for some $P\mathbf{u} > \mathbf{u}$ for some $\mathbf{u} > 0$.

An $n \times n$ **matrix polynomial of degree** d in the (integer) variable m is a polynomial in m with coefficients that are $n \times n$ matrices (expressible as $S(m) = \sum_{t=0}^{d} m^t B_t$ with $B_1, \ldots, B_d$ as $n \times n$ matrices and $B_d \neq 0$).

Facts:

Facts requiring proofs for which no specific reference is given can be found in [BP94, Chap. 2].

1. The set of basic classes of a nonnegative matrix is always nonempty.
2. (*Spectral Properties of the Perron Value*) Let P be a nonnegative $n \times n$ matrix with spectral radius ρ and index ν.
   (a) [Fro12] ρ is an eigenvalue of P.

   (b) [Fro12] There exist semipositive right and left eigenvectors of P corresponding to ρ, i.e., ρ is a distinguished eigenvalue of both P and P^T.

   (c) [Rot75] ν is the largest number of vertices on a simple walk in $R^*(P)$.

   (d) [Rot75] For each basic class B having height h, there exists a generalized eigenvector $\mathbf{v}^B$ in $N_\rho^h(P)$, with $(\mathbf{v}^B)_i > 0$ if $i \mapsto B$ and $(\mathbf{v}^B)_i = 0$ otherwise.

   (e) [Rot75] The dimension of $N_\rho^\nu(P)$ is the number of basic classes of P. Further, if $B_1, \ldots, B_p$ are the basic classes of P and $\mathbf{v}^{B_1}, \ldots, \mathbf{v}^{B_r}$ are generalized eigenvectors of P at ρ that satisfy the conclusions of Fact 2(d) with respect to $B_1, \ldots, B_r$, respectively, then $\mathbf{v}^{B_1}, \ldots, \mathbf{v}^{B_p}$ form a basis of $N_\rho^\nu(P)$.

(f) [RiSc78, Sch86] If $B_1, \ldots, B_p$ is an enumeration of the basic classes of P with nondecreasing heights (in particular, $s < t$ assures that we do not have $B_t \mapsto B_s$), then there exist generalized eigenvectors $\mathbf{v}^{B_1}, \ldots, \mathbf{v}^{B_p}$ of P at ρ that satisfy the assumptions and conclusions of Fact 2(e) and a nonnegative $p \times p$ upper triangular matrix M with all diagonal elements equal to ρ, such that

$$P[\mathbf{v}^{B_1}, \ldots, \mathbf{v}^{B_p}] = [\mathbf{v}^{B_1}, \ldots, \mathbf{v}^{B_p}]M$$

(in particular, $\mathbf{v}^{B_1}, \ldots, \mathbf{v}^{B_p}$ is a basis of $N_\rho^\nu(P)$). Relationships between the matrix M and the Jordan Canonical Form of P are beyond the scope of the current review; see [Sch56], [Sch86], [HS89], [HS91a], [HS91b], [HRS89], and [NS94].

(g) [Vic85], [Sch86], [Tam04] If $B_1, \ldots, B_r$ are the basic classes of P having height 1 and $\mathbf{v}^{B_1}, \ldots, \mathbf{v}^{B_r}$ are generalized eigenvectors of P at ρ that satisfy the conclusions of Fact 2(d) with respect to $B_1, \ldots, B_r$, respectively, then $\mathbf{v}^{B_1}, \ldots, \mathbf{v}^{B_r}$ are linearly independent, nonnegative eigenvectors of P at ρ that span the cone $(\mathbb{R}_0^+)^n \cap N_\rho^1(P)$; that is, each vector in the cone $(\mathbb{R}_0^+)^n \cap N_\rho^1(P)$ is a linear combination with nonnegative coefficients of $\mathbf{v}^{B_1}, \ldots, \mathbf{v}^{B_r}$ (in fact, the sets $\{\alpha \mathbf{v}^{B_s} : \alpha \geq 0\}$ for $s = 1, \ldots, r$ are the the extreme rays of the cone $(\mathbb{R}_0^+)^n \cap N_\rho^1(P)$).

3. (*Spectral Properties of Eigenvalues* $\lambda \neq \rho(P)$ with $|\lambda| = \rho(P)$) Let P be a nonnegative $n \times n$ matrix with spectral radius ρ, index ν, co-index $\bar{\nu}$, period q, and coefficient of ergodicity τ.

(a) [Rot81a] The following are equivalent:

   i. $\{\lambda \in \sigma(P) \setminus \{\rho\} : |\lambda| = \rho\} = \emptyset$.

   ii. $\bar{\nu} = 0$.

   iii. P is aperiodic ($q = 1$).

(b) [Rot81a] If $\lambda \in \sigma(P) \setminus \{\rho\}$ and $|\lambda| = \rho$, then $(\frac{\lambda}{\rho})^h = 1$ for some $h \in \{2, \ldots, n\}$; further, $q = \min\{h = 2, \ldots, n : (\frac{\lambda}{\rho})^h = 1$ for each $\lambda \in \sigma(P) \setminus \{\rho\}$ with $|\lambda| = \rho\} \leq n$ (here the minimum over the empty set is taken to be 1).

(c) [Rot80] If $\lambda \in \sigma(P) \setminus \{\rho\}$ and $|\lambda| = \rho$, then $\nu_P(\lambda)$ is bounded by the largest number of vertices on a simple walk in $R^*(P)$ with each vertex corresponding to a (basic) access equivalence class C that has $\lambda \in \sigma(P[C])$; in particular, $\bar{\nu} \leq \nu$.

4. (*Distinguished Eigenvalues*) Let P be a nonnegative $n \times n$ matrix.

(a) [Vic85] λ is a distinguished eigenvalue of P if and only if there is a final set C with $\rho(P[C]) = \lambda$.

It is noted that the set of distinguished eigenvalues of P and P^T need not coincide (and the above characterization of distinguished eigenvalues is not invariant of the application of the transpose operator). (See Example 1 next.)

(b) [HS88b] If λ is a distinguished eigenvalue, $\nu_P(\lambda)$ is the largest number of vertices on a simple walk in $R^*(P[\lambda])$.

(c) [HS88b] If $\mu > 0$, then $\mu \leq \min\{\lambda : \lambda$ is a distinguished eigenvalue of $P\}$ if and only if there exists a vector $\mathbf{u} > 0$ with $P\mathbf{u} \geq \mu\mathbf{u}$.

(For additional characterizations of the minimal distinguished eigenvalue, see the concluding remarks of Facts 12(h) and 12(i).)

Additional properties of distinguished eigenvalues λ of P that depend on $P[\lambda]$ can be found in [HS88b] and [Tam04].

5. (*Convergence Properties of Powers*) Let P be a nonnegative $n \times n$ matrix with positive spectral radius ρ, index ν, co-index $\bar{\nu}$, period q, and coefficient of ergodicity τ (for the case where $\rho = 0$, see Fact 12(j)).

(a) [Rot81a] There exists an $n \times n$ matrix polynomial $S(m)$ of degree $\nu - 1$ in the (integer) variable m such that $\lim_{m\to\infty}[(\frac{P}{\rho})^m - S(m)] = 0$ (C, p) for every $p \geq \bar{\nu}$; further, if P is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate $\frac{\tau}{\rho} < 1$.

(b) [Rot81a] There exist matrix polynomials $S^0(m), \dots, S^{q-1}(m)$ of degree $\nu - 1$ in the (integer) variable m, such that for each $k = 0, \dots, q-1$, $\lim_{m\to\infty}[(\frac{P}{\rho})^{mq+k} - S^t(m)] = 0$ and the convergence of these sequences to their limit is geometric with rate $(\frac{\tau}{\rho})^q < 1$.

(c) [Rot81a] There exists a matrix polynomial $T(m)$ of degree ν in the (integer) variable m with $\lim_{m\to\infty}[\sum_{s=0}^{m-1}(\frac{P}{\rho})^s - T(m)] = 0$ (C, p) for every $p \geq \bar{\nu}$; further, if P is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate $\frac{\tau}{\rho} < 1$.

(d) [FrSc80] The limit of $\frac{P^m}{\rho^m m^{\nu-1}}[I + \frac{P}{\rho} + \cdots + (\frac{P}{\rho})^{q-1}]$ exists and is semipositive.

(e) [Rot81b] Let $\mathbf{x} = [x_i]$ be a nonnegative vector in $\mathbb{R}^n$ and let $i \in \langle n \rangle$. With $K(i, \mathbf{x}) \equiv \{j \in \langle n \rangle : j \mapsto i\} \cap \{j \in \langle n \rangle : u \mapsto j$ for some $u \in \langle n \rangle$ with $x_u > 0\}$,

$$r(i|\mathbf{x}, P) \equiv \inf\{\alpha > 0 \colon \lim_{m\to\infty} \alpha^{-m}(P^m\mathbf{x})_i = 0\} = \rho(P[K(i,\mathbf{x})])$$

and if $r \equiv r(i|\mathbf{x}, P) > 0$,

$$k(i|\mathbf{x}, P) \equiv \inf\{k = 0, 1, \dots : \lim_{m\to\infty} m^{-k} r^{-m}(P^m\mathbf{x})_i = 0\} = \nu_{P[K(i,\mathbf{x})]}(r).$$

Explicit expressions for the polynomials mentioned in Facts 5(a) to 5(d) in terms of characteristics of the underlying matrix P are available in Fact 12(a)ii for the case where $\nu = 1$ and in [Rot81a] for the general case. In fact, [Rot81a] provides (explicit) polynomial approximations of additional high-order partial sums of normalized powers of nonnegative matrices.

6. (*Bounds on the Perron Value*) Let P be a nonnegative $n \times n$ matrix with spectral radius ρ and let μ be a nonnegative scalar.

(a) For $\diamond \in \{<, \leq, =, \geq, >\}$,

$$[P\mathbf{u} \diamond \mu\mathbf{u} \text{ for some vector } \mathbf{u} > 0] \Rightarrow [\rho \diamond \mu] \ ;$$

further, the inverse implication holds for $\diamond$ as $<$, implying that

$$\rho = \max_{\mathbf{x} \gneq 0} \min_{\{i \,:\, x_i > 0\}} \frac{(A\mathbf{x})_i}{x_i}.$$

(b) For $\diamond \in \{\lneq, \leq, =, \geq, \gneq\}$,

$$[\rho \diamond \mu] \Rightarrow [P\mathbf{u} \diamond \mu\mathbf{u} \text{ for some vector } \mathbf{u} \gneq 0] \ ;$$

further, the inverse implication holds for $\diamond$ as $\geq$.

(c) $\rho < \mu$ if and only if $P\mathbf{u} < \rho\mathbf{u}$ for some vector $\mathbf{u} \geq 0$.

Since $\rho(P^T) = \rho(P)$, the above properties (and characterizations) of ρ can be expressed by applying the above conditions to P^T. (See Example 3 next.)
Some of the above results can be expressed in terms of the Collatz–Wielandt sets. (See Fact 10.2.7 and Chapter 36.)

7. (*Bounds on the Spectral Radius*) Let P be a nonnegative $n \times n$ matrix and let A be a complex $n \times n$ matrix such that $|A| \leq P$. Then $\rho(A) \leq \rho(P)$.

8. (*Functional Inequalities*) Consider the function $\rho(.)$ mapping nonnegative $n \times n$ matrices to their spectral radius.
   (a) $\rho(.)$ is nondecreasing in each element (of the domain matrices); that is, if A and B are nonnegative $n \times n$ matrices with $A \geq B \geq 0$, then $\rho(A) \geq \rho(B)$.
   (b) [Coh78] $\rho(.)$ is (jointly) convex in the diagonal elements; that is, if A and D are $n \times n$ matrices, with D diagonal, A and $A + D$ nonnegative, and if $0 < \alpha < 1$, then $\rho[\alpha A + (1-\alpha)(A+D)] \leq \alpha\rho(A) + (1-\alpha)\rho(A+D)$.
   (c) [EJD88] If $A = [a_{ij}]$ and $B = [b_{ij}]$ are nonnegative $n \times n$ matrices, $0 < \alpha < 1$ and $C = [c_{ij}]$ with $c_{ij} = a_{ij}^{\alpha} b_{ij}^{1-\alpha}$ for each $i, j = 1, \ldots, n$, then $\rho(C) \leq \rho(A)^{\alpha}\rho(B)^{1-\alpha}$.

   Further functional inequalities about $\rho(.)$ can be found in [EJD88] and [EHP90].
9. (*Resolvent Expansions*) Let P be a nonnegative square matrix with spectral radius ρ and let $\mu > \rho$. Then $\mu I - P$ is invertible and

$$(\mu I - P)^{-1} = \sum_{t=0}^{\infty} \frac{P^t}{\mu^{t+1}} \geq \frac{I}{\mu} + \frac{P}{\mu^2} \geq \frac{I}{\mu} \geq 0$$

   (the invertibility of $\mu I - P$ and the power series expansion of its inverse do not require nonnegativity of P).

   For explicit expansions of the resolvent about the spectral radius, that is, for explicit power series representations of $[(z+\rho)I - P]^{-1}$ with $|z|$ positive and sufficiently small, see [Rot81c] and [HNR90] (the latter uses such expansions to prove Perron–Frobenius-type spectral results for nonnegative matrices).
10. (*Puiseux Expansions of the Perron Value*) [ERS95] The function $\rho(.)$ mapping irreducible nonnegative $n \times n$ matrices $X = [x_{ij}]$ to their spectral radius has a converging Puiseux (fractional power series) expansion at each point; i.e., if P is a nonnegative $n \times n$ matrix and if F is an $n \times n$ matrix with $P + \epsilon F \geq 0$ for all sufficiently small positive ϵ, then $\rho(P + \epsilon F)$ has a representation $\sum_{k=0}^{\infty} \rho_k \epsilon^{k/q}$ with $\rho_0 = \rho(P)$ and q as a positive integer.
11. (*Bounds on the Ergodicity Coefficient*) [RT85, extension of Theorem 3.1] Let P be a nonnegative $n \times n$ matrix with spectral radius ρ, corresponding semipositive right eigenvector $\mathbf{v}$, and ergodicity coefficient τ, let D be a diagonal $n \times n$ matrix with positive diagonal elements, and let $\|.\|$ be a norm on $\mathbb{R}^n$. Then

$$\tau \leq \max_{\mathbf{x} \in \mathbb{R}^n, \|\mathbf{x}\| \leq 1, \mathbf{x}^T D^{-1}\mathbf{v} = 0} \|\mathbf{x}^T D^{-1} P D\|.$$

12. (*Special Cases*) Let P be a nonnegative $n \times n$ matrix with spectral radius ρ, index ν, and period q.
   (a) (Index 1) Suppose $\nu = 1$.
      i. $\rho I - P$ has a group inverse.
      ii. [Rot81a] With $P^{\star} \equiv I - (\rho I - P)(\rho I - P)^{\#}$, all of the convergence properties stated in Fact 10.2.6 apply.
      iii. If $\rho > 0$, then $\frac{P^m}{\rho^m}$ is bounded in m (element-wise).
      iv. $\rho = 0$ if and only if $P = 0$.
   (b) (*Positive eigenvector*) The following are equivalent:
      i. P has a positive right eigenvector corresponding to ρ.
      ii. The final classes of P are precisely its basic classes.
      iii. There is no vector $\mathbf{w}$ satisfying $\mathbf{w}^T P \lneq \rho \mathbf{w}^T$.

   Further, when the above conditions hold:

   i. $\nu = 1$ and the conclusions of Fact 12(a) hold.
   ii. If P satisfies the above conditions and $P \neq 0$, then $\rho > 0$ and there exists a diagonal matrix D having positive diagonal elements such that $S \equiv \frac{1}{\rho} D^{-1} P D$ is stochastic (that is, $S \geq 0$ and $S\mathbf{1} = \mathbf{1}$; see Chapter 4).

(c) [Sch53] There exists a vector $\mathbf{x} > 0$ with $P\mathbf{x} \leq \rho x$ if and only if every basic class of P is final.

(d) (*Positive generalized eigenvector*) [Rot75], [Sch86], [HS88a] The following are equivalent:

   i. P has a positive right generalized eigenvector at ρ.
   ii. Each final class of P is basic.
   iii. $P\mathbf{u} \geq \rho\mathbf{u}$ for some $\mathbf{u} > 0$.
   iv. Every vector $\mathbf{w} \geq 0$ with $\mathbf{w}^T P \leq \rho \mathbf{w}^T$ must satisfy $\mathbf{w}^T P = \rho \mathbf{w}^T$.
   v. ρ is the only distinguished eigenvalue of P.

(e) (*Convergent/Transient*) The following are equivalent:

   i. P is convergent.
   ii. $\rho < 1$.
   iii. $I - P$ is invertible and $(I-P)^{-1} \geq 0$.
   iv. There exists a positive vector $\mathbf{u} \in R^n$ with $P\mathbf{u} < \mathbf{u}$.

   Further, when the above conditions hold, $(I-P)^{-1} = \sum_{t=0}^{\infty} P^t \geq I$.

(f) (*Semiconvergent*) The following are equivalent:

   i. P is semiconvergent.
   ii. Either $\rho < 1$ or $\rho = \nu = 1$ and 1 is the only eigenvalue λ of P with $|\lambda| = 1$.

(g) (*Bounded*) P^m is bounded in m (element-wise) if and only if either $\rho < 1$ or $\rho = 1$ and ν=1.

(h) (*Weakly Expanding*) [HS88a], [TW89], [DR05] The following are equivalent:

   i. P is weakly expanding.
   ii. There is no vector $\mathbf{w} \in R^n$ with $\mathbf{w} \geq 0$ and $w^T P \lneq w^T$.
   iii. Every distinguished eigenvalue λ of P satisfies $\lambda \geq 1$.
   iv. Every final class C of P has $\rho(P[C]) \geq 1$.
   v. If C is a final set of P, then $\rho(P[C]) \geq 1$.

   Given $\mu > 0$, the application of the above equivalence to $\frac{P}{\mu}$ yields characterizations of instances where each distinguished eigenvalue of P is bigger than or equal to μ.

(i) (*Expanding*) [HS88a], [TW89], [DR05] The following are equivalent:

   i. P is expanding.
   ii. There exists a vector $\mathbf{u} \in R^n$ with $\mathbf{u} \geq 0$ and $P\mathbf{u} > \mathbf{u}$.
   iii. There is no vector $\mathbf{w} \in R^n$ with $\mathbf{w} \gneq 0$ and $w^T P \leq w^T$.
   iv. Every distinguished eigenvalue λ of P satisfies $\lambda > 1$.
   v. Every final class C of P has $\rho(P[C]) > 1$.
   vi. If C is a final set of P, then $\rho(P[C]) > 1$.

   Given $\mu > 0$, the application of the above equivalence to $\frac{P}{\mu}$ yields characterizations of instances where each distinguished eigenvalue of P is bigger than μ.

(j) (*Nilpotent*) The following are equivalent conditions:

   i. P is nilpotent; that is, $P^m = 0$ for some positive integer m.

ii. P is permutation similar to an upper triangular matrix all of whose diagonal elements are 0.

iii. $\rho = 0$.

iv. $P^n = 0$.

v. $P^\nu = 0$.

(k) (*Symmetric*) Suppose P is symmetric.

i. $\rho = \max_{\mathbf{u} \gneq 0} \frac{\mathbf{u}^T P \mathbf{u}}{\mathbf{u}^T \mathbf{u}}$.

ii. $\rho = \frac{\mathbf{u}^T P \mathbf{u}}{\mathbf{u}^T \mathbf{u}}$ for $\mathbf{u} \gneq 0$ if and only if $\mathbf{u}$ is an eigenvector of P corresponding to ρ.

iii. [CHR97, Theorem 1] For $\mathbf{u}, \mathbf{w} \gneq 0$ with $w_i = \sqrt{u_i (Pu)_i}$ for $i = 1, \ldots, n$, $\frac{\mathbf{u}^T P \mathbf{u}}{\mathbf{u}^T \mathbf{u}} \leq \frac{\mathbf{w}^T P \mathbf{w}}{\mathbf{w}^T \mathbf{w}}$ and equality holds if and only if $\mathbf{u}[\mathcal{S}]$ is an eigenvector of $P[\mathcal{S}]$ corresponding to ρ, where $\mathcal{S} \equiv \{i : u_i > 0\}$.

Examples:

1. We illustrate parts of Fact 2 using the matrix

$$P = \begin{bmatrix} 2 & 2 & 2 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 2 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

The eigenvalues of P are 2, 1, and 0; so, $\rho(P) = 2 \in \sigma(P)$ as is implied by Fact 2(a). The vectors $\mathbf{v} = [1, 0, 0, 0, 0, 0]^T$ and $\mathbf{w} = [0, 0, 0, 1, 1, 1]$ are semipositive right and left eigenvectors corresponding to the eigenvalue 2; their existence is implied by Fact 2(b).

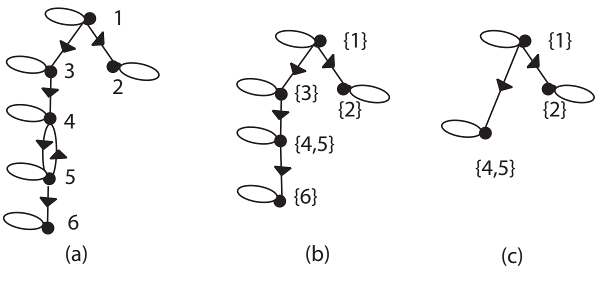

FIGURE 10.1 (a) The digraph $\Gamma(P)$, (b) reduced digraph $R[\Gamma(P)]$, and (c) basic reduced digraph $R^*(P)$.

The basic classes are $B_1 = \{1\}, B_1 = \{2\}$ and $B_3 = \{4, 5\}$. The digraph corresponding to P, its reduced digraph, and the basic reduced digraph of P are illustrated in Figure 10.1. From Figure 10.1(c), the largest number of vertices in a simple walk in the basic reduced digraph of P is 2 (going from B_1 to either B_2 or B_3); hence, Fact 2(c) implies that $\nu_P(2) = 2$. The height of basic class B_1 is 1 and the height of basic classes B_2 and B_3 is 2. Semipositive generalized eigenvectors of P at (the eigenvalue) 2 that satisfy the assumptions of Fact 2(f) are $\mathbf{u}^{B_1} = [1, 0, 0, 0, 0, 0]^T$, $\mathbf{u}^{B_2} = [1, 1, 0, 0, 0, 0]^T$, and $\mathbf{u}^{B_3} = [1, 0, 2, 1, 1, 0]^T$. The implied equality

$$P[\mathbf{u}^{B_1}, \ldots, \mathbf{u}^{B_p}] = [\mathbf{u}^{B_1}, \ldots, \mathbf{u}^{B_p}]M$$

of Fact 2(f) holds as

$$\begin{bmatrix} 2&2&2&0&0&0\\ 0&2&0&0&0&0\\ 0&0&1&2&0&0\\ 0&0&0&1&1&0\\ 0&0&0&1&1&1\\ 0&0&0&0&0&1 \end{bmatrix} \begin{bmatrix} 1&1&1\\ 0&1&0\\ 0&0&2\\ 0&0&1\\ 0&0&1\\ 0&0&0 \end{bmatrix} = \begin{bmatrix} 2&4&6\\ 0&2&0\\ 0&0&4\\ 0&0&2\\ 0&0&2\\ 0&0&0 \end{bmatrix} = \begin{bmatrix} 1&1&1\\ 0&1&0\\ 0&0&2\\ 0&0&1\\ 0&0&1\\ 0&0&0 \end{bmatrix} \begin{bmatrix} 2&2&4\\ 0&2&0\\ 0&0&2 \end{bmatrix}.$$

In particular, Fact 2(e) implies that $\mathbf{u}^{B_1}, \mathbf{u}^{B_2}, \mathbf{u}^{B_3}$ form a basis of $N_{\rho(P)}^{\nu(P)} = N_2^2$. We note that while there is only a single basic class of height 1, $\dim[N_\rho^1(P)] = 2$ and $\mathbf{u}^{B_1}, 2\mathbf{u}^{B_2} - \mathbf{u}^{B_3} = [-1, 2, -2, -1, -1, 0]^T$ form a basis of $N_\rho^1(P)$. Still, Fact 2(g) assures that $(\mathbb{R}_0^+)^n \cap N_\rho^1(P)$ is the cone $\{\alpha\mathbf{u}^{B_1} : \alpha \geq 0\}$ (consisting of its single ray).

Fact 4(a) and Figure 10.1 imply that the distinguished eigenvalues of P are 1 and 2, while 2 is the only distinguished eigenvalue of P^T.

2. Let $H = \begin{bmatrix} 0&1\\ 1&0 \end{bmatrix}$; properties of H were demonstrated in Example 10.2.2. We will demonstrate Facts 2(c), 5(b), and 5(a) on the matrix

$$P \equiv \begin{bmatrix} H & I\\ 0 & H \end{bmatrix}.$$

The spectral radius of P is 1 and its basic classes of P are $B_1 = \{1, 2\}$ and $B_2 = \{3, 4\}$ with B_1 having access to B_2. Thus, the index of 1 with respect to P, as the largest number of vertices on a walk of the marked reduced graph of P, is 2 (Fact 2(c)). Also, as the period of each of the two basic classes of P is 2, the period of P is 2. To verify the convergence properties of P, note that

$$P^m = \begin{cases} \begin{bmatrix} I & mH\\ 0 & I \end{bmatrix} & \text{if } m \text{ is even}\\[2ex] \begin{bmatrix} H & mI\\ 0 & H \end{bmatrix} & \text{if } m \text{ is odd,} \end{cases}$$

immediately providing matrix–polynomials $S^0(m)$ and $S^1(m)$ of degree 1 such that $\lim_{m\to\infty} P^{2m} - S^0(m) = 0$ and $\lim_{m\to\infty} P^{2m+1} - S^1(m) = 0$. In this example, $\tau(P)$ is 0 (as the maximum over the empty set) and the convergence of the above sequences is geometric with rate 0.

The above representation of P^m shows that

$$P^m = \begin{bmatrix} H^m & mH^{m+1}\\ 0 & H^m \end{bmatrix}$$

and Example 10.2.2 shows that

$$\lim_{m\to\infty} H^m = \frac{I+H}{2} = \begin{bmatrix} .5 & .5\\ .5 & .5 \end{bmatrix} \quad \text{(C,1)}.$$

We next consider the upper-right blocks of P^m. We observe that

$$\begin{aligned} \frac{1}{m}\sum_{t=0}^{m-1} P^t[B_1, B_2] &= \begin{cases} \frac{mI}{4} + \frac{(m-2)H}{4} & \text{if } m \text{ is even}\\ \frac{(m-1)^2 I}{4m} + \frac{(m^2-1)H}{4m} & \text{if } m \text{ is odd,} \end{cases}\\ &= \begin{cases} \frac{m(I+H)}{4} - \frac{H}{2} & \text{if } m \text{ is even}\\ \frac{m(I+H)}{4} - \frac{I}{2} + \frac{I-H}{4m} & \text{if } m \text{ is odd,} \end{cases} \end{aligned}$$

implying that

$$\lim_{m\to\infty}\frac{1}{m}\sum_{t=0}^{m-1}P^t[B_1,B_2]-m\left(\frac{I+H}{4}\right)+\frac{I+H}{4}=0\quad(\mathrm{C},1)\,.$$

As $m-1=\frac{1}{m}\sum_{t=0}^{m-1}t$ for each $m=1,2,\ldots,$ the above shows that

$$\lim_{m\to\infty}\frac{1}{m}\sum_{t=0}^{m-1}\left\{P^t[B_1,B_2]-t\left(\frac{I+H}{4}\right)\right\}=0\quad(\mathrm{C},1),$$

and, therefore (recalling that (C,1)-convergence implies (C,2)-convergence),

$$\lim_{m\to\infty}\left\{P^m-\begin{bmatrix}.5&.5&-.25m&-.25m\\.5&.5&-.25m&-.25m\\0&0&.5&.5\\0&0&.5&.5\end{bmatrix}\right\}=0\quad(\mathrm{C},2).$$

3. Fact 6 implies many equivalencies, in particular, as the spectral radius of a matrix equals that of its transpose. For example, for a nonnegative $n\times n$ matrix P with spectral radius ρ and nonnegative scalar μ, the following are equivalent:
   (a) $\rho<\mu$.
   (b) $P\mathbf{u}<\mu\mathbf{u}$ for some vector $\mathbf{u}>0$.
   (c) $\mathbf{w}^TP<\mu\mathbf{w}^T$ for some vector $\mathbf{w}>0$.
   (d) $P\mathbf{u}<\rho\mathbf{u}$ for some vector $\mathbf{u}\geq 0$.
   (e) $\mathbf{w}^TP<\rho\mathbf{w}^T$ for some vector $\mathbf{w}\geq 0$.
   (f) There is no vector $\mathbf{u}\gneq 0$ satisfying $P\mathbf{u}\geq\mu\mathbf{u}$.
   (g) There is no vector $\mathbf{w}\gneq 0$ satisfying $\mathbf{w}^TP\geq\mu\mathbf{w}^T$.

10.4 Stochastic and Substochastic Matrices

For more information about stochastic matrices see Chapter 72 (including examples).

Definitions:

A square $n\times n$ matrix $P=[p_{ij}]$ is **stochastic** if it is nonnegative and $P\mathbf{1}=\mathbf{1}$ where $\mathbf{1}=[1,\ldots,1]^T\in R^n$. (Stochastic matrices are sometimes referred to as **row-stochastic**, while **column-stochastic** matrices are matrices whose transpose is (row-)stochastic.)

A square $n\times n$ matrix P is **doubly stochastic** if both P and its transpose are stochastic. The set of doubly stochastic matrices of order n is denoted Ω_n.

A square $n\times n$ matrix P is **substochastic** if it is nonnegative and $P\mathbf{1}\leq\mathbf{1}$.

A transient substochastic matrix is also called **stopping**.

An **ergodic class** of a stochastic matrix P is a basic class of P.

A **transient class** of a stochastic matrix P is an access equivalence class of P which is not ergodic.

A **state** of an $n\times n$ stochastic matrix P is an index $i\in\{1,\ldots,n\}$. Such a state is **ergodic** or **transient** depending on whether it belongs to an ergodic class or to a transient class.

A **stationary distribution** of a stochastic matrix P is a nonnegative vector $\boldsymbol{\pi}$ that satisfies $\boldsymbol{\pi}^T\mathbf{1}=1$ and $\boldsymbol{\pi}^TP=\boldsymbol{\pi}^T$.

Facts:

Facts requiring proofs for which no specific reference is given follow directly from facts in Sections 10.2 and 10.3 or can be found in [BP94, Chap. 8].

1. Let $P = [p_{ij}]$ be an $n \times n$ stochastic matrix.
   (a) $\rho(P) = 1$, $1 \in R^n$ is a right eigenvector of P corresponding to 1 and the stationary distributions of P are nonnegative eigenvectors of P corresponding to 1.
   (b) $\nu_P(1) = 1$.
   (c) $I - P$ has a group inverse.
   (d) The height of every ergodic class is 1.
   (e) The final classes of P are precisely its ergodic classes.
   (f) i. For every ergodic class C, P has a unique stationary distribution $\boldsymbol{\pi}^C$ of P with $(\boldsymbol{\pi}^C)_i > 0$ if $i \in C$ and $(\boldsymbol{\pi}^C)_i = 0$ otherwise.
      ii. If $C^1, \ldots, C^p$ are the ergodic classes of P, then the corresponding stationary distributions $\boldsymbol{\pi}^{C^1}, \ldots, \boldsymbol{\pi}^{C^p}$ (according to Fact 1(f)i) form a basis of the set of left eigenvectors of P corresponding to the eigenvalue 1; further, every stationary distribution of P is a convex combination of these vectors.
   (g) i. Let T and R be the sets of transient and ergodic states of P, respectively. The matrix $I - P[T]$ is nonsingular and for each ergodic class C of P, the vector u^C given by

$$(\mathbf{u}^C)[K] = \begin{cases} e & \text{if } K = C \\ 0 & \text{if } K = R \setminus C \\ (I - P[T])^{-1} P[T, C] e & \text{if } K = T \end{cases}$$

      is a right eigenvector of P corresponding to the eigenvalue 1; in particular, $(\mathbf{u}^C)_i > 0$ if i has access to C and $(\mathbf{u}^C)_i = 0$ if i does not have access to C.
      ii. If $C^1, \ldots, C^p$ are the ergodic classes of P, then the corresponding vectors $\mathbf{u}^{C^1}, \ldots, \mathbf{u}^{C^p}$ (referred to in Fact 1(g)i) form a basis of the set of right eigenvectors of P corresponding to the eigenvalue 1; further, $\sum_{t=1}^{p} \mathbf{u}^{C^t} = e$.
   (h) Let $C^1, \ldots, C^p$ be the ergodic classes of P, $\boldsymbol{\pi}^{C^1}, \ldots, \boldsymbol{\pi}^{C^p}$ the corresponding stationary distributions (referred to in Fact 1(f)i), and $\mathbf{u}^{C^1}, \ldots, \mathbf{u}^{C^p}$ the corresponding eigenvectors referred to in Fact 1(g)i. Then the matrix

$$P^\star = \left[\mathbf{u}^{C^1}, \ldots, \mathbf{u}^{C^p}\right] \begin{bmatrix} \boldsymbol{\pi}^{C^1} \\ \vdots \\ \boldsymbol{\pi}^{C^p} \end{bmatrix}$$

   is stochastic and satisfies $P^\star[\langle n \rangle, C] = 0$ if C is a transient class of P, $P^\star[i, C] \neq 0$ if C is an ergodic class and i has access to C, and $P^\star[i, C] = 0$ if C is an ergodic class and i does not have access to C.
   (i) The matrix $P^\star$ from Fact 1(h) has the representation $I - (I-P)^\#(I-P)$; further, $I - P + P^\star$ is nonsingular and $(I - P)^\# = (I - P + P^\star)^{-1}(I - P^\star)$.
   (j) With $P^\star$ as the matrix from Fact 1(h), $\lim_{m\to\infty} P^m = P^\star$ (C,1); further, when P is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate $\tau(P) < 1$.
   (k) With $P^\star$ as the matrix from Fact 1(h), $\lim_{m\to\infty} \sum_{t=0}^{m-1} P^t - mP^\star = (I - P)^\#$ (C,1); further, when P is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate $\tau(P) < 1$.

(l) With D a diagonal $n \times n$ matrix with positive diagonal elements and $\|.\|$ a norm on $\mathbb{R}^n$,

$$\tau(P) \leq \max_{\mathbf{x}\in\mathbb{R}^n, \|\mathbf{x}\|\leq 1, \mathbf{x}^T D^{-1}\mathbf{1}=0} \|\mathbf{x}^T D^{-1} P D\|.$$

In particular, with $\|.\|$ as the 1-norm on $\mathbb{R}^n$ and $D = I$, the above bound specializes to

$$\tau(P) \leq \max_{r,s=1,\ldots,n, r\neq s} \sum_{k=1}^{n} \frac{|p_{rk} - p_{sk}|}{2} \leq \min\left\{1 - \sum_{k=1}^{n} \min_r p_{rk}, \sum_{k=1}^{n} \max_r p_{rk} - 1\right\}$$

(cf. Fact 10.3.11 and Example 10.2.4).

(m) For every $0 < \alpha < 1$, $P_\alpha \equiv (1-\alpha)I + \alpha P$ is an aperiodic stochastic matrix whose ergodic classes, transient classes, stationary distributions, and the vectors of Fact 1(g)i coincide with those of P. In particular, with $P^\star$ and $P_\alpha^\star$ as the matrices from Fact 1(h) corresponding to P and P_α, respectively, $\lim_{m\to\infty}(P_\alpha)^m = P_\alpha^\star = P^\star$.

2. Let P be an irreducible stochastic matrix with coefficient of ergodicity τ.

   (a) P has a unique stationary distribution, say $\boldsymbol{\pi}$. Also, up to scalar multiple, $\mathbf{1}$ is a unique right eigenvector or P corresponding to the eigenvalue 1.

   (b) With $\boldsymbol{\pi}$ as the unique stationary distribution of P, the matrix $P^\star$ from Fact 1(h) equals $\mathbf{1}\boldsymbol{\pi}$.

3. A doubly stochastic matrix is a convex combination of permutation matrices (in fact, the $n \times n$ permutation matrices are the extreme points of the set Ω_n of $n \times n$ doubly stochastic matrices).
4. Let P be an $n \times n$ substochastic matrix.

   (a) $\rho(P) \leq 1$.

   (b) $\nu_P(1) \leq 1$.

   (c) $I - P$ has a group inverse.

   (d) The matrix $P^\star \equiv I - (I-P)^\#(I-P)$ is substochastic; further, $I - P + P^\star$ is nonsingular and $(I-P)^\# = (I - P + P^\star)^{-1}(I - P^\star)$.

   (e) With $P^\star$ as in Fact 4(d), $\lim_{m\to\infty} P^m = P^\star$ (C,1); further, when every access equivalence class C with $\rho(P[C]) = 1$ is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate $\max\{|\lambda| : \lambda \in \sigma(P) \text{ and } |\lambda| \neq 1\} < 1$.

   (f) With $P^\star$ as the matrix from Fact 4(d), $\lim_{m\to\infty} \sum_{t=0}^{m-1} P^t - mP^\star = (I-P)^\#$ (C,1); further, when every access equivalence class C with $\rho(P[C]) = 1$ is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate $\max\{|\lambda| : \lambda \in \sigma(P) \text{ and } |\lambda| \neq 1\} < 1$.

   (g) The following are equivalent:

      i. P is stopping.

      ii. $\rho(P) < 1$.

      iii. $I - P$ is invertible.

      iv. There exists a positive vector $\mathbf{u} \in R^n$ with $P\mathbf{u} < \mathbf{u}$.

   Further, when the above conditions hold, $(I-P)^{-1} = \sum_{t=0}^{\infty} P^t \geq 0$.

10.5 M-matrices

Definitions:

An $n \times n$ real matrix $A = [a_{ij}]$ is a ***Z*-matrix** if its off-diagonal elements are nonpositive, i.e., if $a_{ij} \leq 0$ for all $i, j = 1, \ldots, n$ with $i \neq j$.

An **M_0-matrix** is a Z-matrix A that can be written as $A = sI - P$ with P as a nonnegative matrix and with s as a scalar satisfying $s \geq \rho(P)$.

An ***M*-matrix** A is a Z-matrix A that can be written as $A = sI - P$ with P as a nonnegative matrix and with s as a scalar satisfying $s > \rho(P)$.

A square real matrix A is an **inverse *M*-matrix** if it is nonsingular and its inverse is an M-matrix.

A square real matrix A is **inverse-nonnegative** if it is nonsingular and $A^{-1} \geq 0$ (the property is sometimes referred to as **inverse-positivity**).

A square real matrix A has a **convergent regular splitting** if A has a representation $A = M - N$ such that $N \geq 0$, M invertible with $M^{-1} \geq 0$ and $M^{-1}N$ is convergent.

A square complex matrix A is **positive stable** if the real part of each eigenvalue of A is positive; A is **nonnegative stable** if the real part of each eigenvalue of A is nonnegative.

An $n \times n$ complex matrix $A = [a_{ij}]$ is **strictly diagonally dominant (diagonally dominant)** if $|a_{ii}| > \sum_{j=1, j\neq i}^{n} |a_{ij}|$ ($|a_{ii}| \geq \sum_{j=1, j\neq i}^{n} |a_{ij}|$) for $i = 1, \ldots, n$.

An $n \times n$ M-matrix A **satisfies property C** if there exists a representation of A of the form $A = sI - P$ with $s > 0$, $P \geq 0$ and $\frac{P}{s}$ semiconvergent.

Facts:

Facts requiring proofs for which no specific reference is given follow directly from results about nonnegative matrices stated in Sections 10.2 and 10.3 or can be found in [BP94, Chap. 6].

1. Let A be an $n \times n$ real matrix with $n \geq 2$. The following are equivalent:
    (a) A is an M-matrix; that is, A is a Z-matrix that can be written as $sI - P$ with P nonnegative and $s > \rho(P)$.
    (b) A is a nonsingular M_0-matrix.
    (c) For each nonnegative diagonal matrix D, $A + D$ is inverse-nonnegative.
    (d) For each $\mu \geq 0$, $A + \mu I$ is inverse-nonnegative.
    (e) Each principal submatrix of A is inverse-nonnegative.
    (f) Each principal submatrix of A of orders $1, \ldots, n$ is inverse-nonnegative.
2. Let $A = [a_{ij}]$ be an $n \times n$ Z-matrix. The following are equivalent:[*]
    (a) A is an M-matrix.
    (b) Every real eigenvalue of A is positive.
    (c) $A + D$ is nonsingular for each nonnegative diagonal matrix D.
    (d) All of the principal minors of A are positive.
    (e) For each $k = 1, \ldots, n$, the sum of all the $k \times k$ principal minors of A is positive.

---

[*] Each of the 17 conditions that are listed in Fact 2 is a representative of a set of conditions that are known to be equivalent for all matrices (not just Z-matrices); see [BP94, Theorem 6.2.3]. For additional characterizations of M-matrices, see [FiSc83].

   - (f) There exist lower and upper triangular matrices L and U, respectively, with positive diagonal elements such that $A = LU$.
   - (g) A is permutation similar to a matrix satisfying Fact 2(f).
   - (h) A is positive stable.
   - (i) There exists a diagonal matrix D with positive diagonal elements such that $AD + DA^T$ is positive definite.
   - (j) There exists a vector $\mathbf{x} > 0$ with $A\mathbf{x} > 0$.
   - (k) There exists a vector $\mathbf{x} > 0$ with $A\mathbf{x} \gneq 0$ and $\sum_{j=1}^{i} a_{ij}x_j > 0$ for $i = 1, \ldots, n$.
   - (l) A is permutation similar to a matrix satisfying Fact 2(k).
   - (m) There exists a vector $\mathbf{x} > 0$ such that $A\mathbf{x} \gneq 0$ and the matrix $\hat{A} = [\hat{a}_{ij}]$ defined by

     $$\hat{a}_{ij} = \begin{cases} 1 & \text{if either } a_{ij} \neq 0 \text{ or } (A\mathbf{x})_i \neq 0 \\ 0 & \text{otherwise} \end{cases}$$

     is irreducible.
   - (n) All the diagonal elements of A are positive and there exists a diagonal matrix D such that AD is strictly diagonally dominant.
   - (o) A is inverse-nonnegative.
   - (p) Every representation of A of the form $A = M - N$ with $N \geq 0$ and M inverse-positive must have $M^{-1}N$ convergent (i.e., $\rho(M^{-1}N) < 1$).
   - (q) For each vector $\mathbf{y} \geq 0$, the set $\{\mathbf{x} \geq 0 : A^T\mathbf{x} \leq \mathbf{y}\}$ is bounded and A is nonsingular.

3. Let A be an irreducible $n \times n$ Z-matrix with $n \geq 2$. The following are equivalent:
   - (a) A is an M-matrix.
   - (b) A is a nonsingular and $A^{-1} > 0$.
   - (c) $A\mathbf{x} \gneq 0$ for some $\mathbf{x} > 0$.
4. Let $A = [a_{ij}]$ be an $n \times n$ M-matrix and let $B = [b_{ij}]$ be an $n \times n$ Z-matrix with $B \geq A$. Then:
   - (a) B is an M-matrix.
   - (b) $\det B \geq \det A$.
   - (c) $A^{-1} \geq B^{-1}$.
   - (d) $\det A \leq a_{11} \ldots a_{nn}$.
5. If P is an inverse M-matrix, then $P \geq 0$ and $\Gamma(P)$ is transitive; that is, if (v, u) and (u, w) are arcs of $\Gamma(P)$, then so is (v, w).
6. Let A be an $n \times n$ real matrix with $n \geq 2$. The following are equivalent:
   - (a) A is a nonsingular M_0-matrix.
   - (b) For each diagonal matrix D with positive diagonal elements, $A + D$ is inverse-nonnegative.
   - (c) For each $\mu > 0$, $A + \mu I$ is inverse-nonnegative.
7. Let A be an $n \times n$ Z-matrix. The following are equivalent:*

---

*Each of the 9 conditions that are listed in Fact 7 is a representative of a set of conditions that are known to be equivalent for all matrices (not just Z-matrices); see [BP94, Theorem 6.4.6]. For additional characterizations of M-matrices, see [FiSc83].

   (a) A is an M_0-matrix.
   (b) Every real eigenvalue of A is nonnegative.
   (c) $A+D$ is nonsingular for each diagonal matrix D having positive diagonal elements.
   (d) For each $k = 1, \dots, n$, the sum of all the $k \times k$ principal minors of A is nonnegative.
   (e) A is permutation similar to a matrix having a representation LU with L and U as lower and upper triangular matrices having positive diagonal elements.
   (f) A is nonnegative stable.
   (g) There exists a nonnegative matrix Y satisfying $YA^{k+1} = A^k$ for some $k \geq 1$.
   (h) A has a representation of the form $A = M - N$ with M inverse-nonnegative, $N \geq 0$ and $B \equiv M^{-1}N$ satisfying $\cap_{k=0}^{\infty}\text{range}(B^k) = \cap_{k=0}^{\infty}\text{range}(A^k)$ and $\rho(B) \leq 1$.
   (i) A has a representation of the form $A = M - N$ with M inverse-nonnegative, $M^{-1}N \geq 0$ and $B \equiv M^{-1}N$ satisfying $\cap_{k=0}^{\infty}\text{range}(B^k) = \cap_{k=0}^{\infty}\text{range}(A^k)$ and $\rho(B) \leq 1$.

8. Let A be an M_0-matrix.
   (a) A satisfies property C if and only if $\nu_A(0) \leq 1$.
   (b) A is permutation similar to a matrix having a representation LU with L as a lower triangular M-matrix and U as an upper triangular M_0 matrix.
9. [BP94, Theorem 8.4.2] If P is substochastic (see Section 10.4), then $I - P$ is an M_0-matrix satisfying property C.
10. Let A be an irreducible $n \times n$ singular M_0-matrix.
   (a) A has rank $n - 1$.
   (b) There exists a vector $\mathbf{x} > 0$ such that $A\mathbf{x} = 0$.
   (c) A has property C.
   (d) Each principal submatrix of A other than A itself is an M-matrix.
   (e) $[A\mathbf{x} \geq 0] \Rightarrow [A\mathbf{x} = 0]$.

10.6 Scaling of Nonnegative Matrices

A scaling of a (usually nonnegative) matrix is the outcome of its pre- and post-multiplication by diagonal matrices having positive diagonal elements. Scaling problems concern the search for scalings of given matrices such that specified properties are satisfied. Such problems are characterized by:

(a) The class of matrices to be scaled.
(b) Restrictions on the pre- and post-multiplying diagonal matrices to be used.
(c) The target property.

Classes of matrices under (a) may refer to arbitrary rectangular matrices, square matrices, symmetric matrices, positive semidefinite matrices, etc. For possible properties of pre- and post-multiplying diagonal matrices under (b) see the following definitions. Finally, examples for target properties under (c) include:

i. The specification of the row- and/or column-sums; for example, being stochastic or being doubly stochastic. See the following facts.
ii. The specification of the row- and/or column-maxima.

iii. (For a square matrix) being line-symmetric, that is, having each row-sum equal to the corresponding column-sum.
iv. Being optimal within a prescribed class of scalings under some objective function. One example of such optimality is to minimize the maximal element of a scalings of the form XAX^{-1}. Also, in numerical analysis, preconditioning a matrix may involve its replacement with a scaling that has a low ratio of largest to smallest element; so, a potential target property is to be a minimizer of this ratio among all scalings of the underlying matrix.

Typical questions that are considered when addressing scaling problems include:

(a) Characterizing existence of a scaling that satisfies the target property (precisely of approximately).
(b) Computing a scaling of a given matrix that satisfies the target property (precisely or approximately) or verifying that none exists.
(c) Determining complexity bounds for corresponding computation.

Early references that address scaling problems include [Kru37], which describes a heuristic for finding a doubly stochastic scaling of a positive square matrix, and Sinkhorn's [Sin64] pioneering paper, which provides a formal analysis of that problem. The subject has been intensively studied and an aspiration to provide a comprehensive survey of the rich literature is beyond the scope of the current review; consequently, we address only scaling problems where the target is to achieve, precisely or approximately, prescribed row- and column-sums.

Definitions:

Let $A = [a_{ij}]$ be an $m \times n$ matrix.

A **scaling** (sometimes referred to as an **equivalence-scaling** or a DAE**-scaling**) of A is any matrix of the form DAE where D and E are square diagonal matrices having positive diagonal elements; such a scaling is a **row-scaling** of A if $E = I$ and it is a **normalized-scaling** if $\det(D) = \det(E) = 1$.

If $m = n$, a scaling DAE of A is a **similarity-scaling** (sometimes referred to as a DAD^{-1} **scaling**) of A if $E = D^{-1}$, and DAE is a **symmetric-scaling** (sometimes referred to as a DAD **scaling**) of A if $E = D$.

The **support** (or **sparsity pattern**) of A, denoted $\mathrm{Struct}(A)$, is the set of indices ij with $a_{ij} \neq 0$; naturally, this definition applies to vectors.

Facts:

1. (*Prescribed-Line-Sum Scalings*) [RoSc89] Let $A = [a_{ij}] \in \mathbb{R}^{m\times n}$ be a nonnegative matrix, and let $\mathbf{r} = [r_i] \in \mathbb{R}^m$ and $\mathbf{c} = [c_j] \in \mathbb{R}^n$ be positive vectors.
   (a) The following are equivalent:
      i. There exists a scaling B of A with $B\mathbf{1} = \mathbf{r}$ and $\mathbf{1}^T B = \mathbf{c}^T$.
      ii. There exists nonnegative $m \times n$ matrix B having the same support as A with $B\mathbf{1} = \mathbf{r}$ and $\mathbf{1}^T B = \mathbf{c}^T$.
      iii. For every $I \subseteq \{1, \ldots, m\}$ and $J \subseteq \{1, \ldots, m\}$ for which $A[I^c, J] = 0$,
      $$\sum_{i\in I} r_i \geq \sum_{j\in J} c_j$$
      and equality holds if and only if $A[I, J^c] = 0$.
      iv. $\mathbf{1}^T\mathbf{r} = \mathbf{1}^T\mathbf{r}$ and the following (geometric) optimization problem has an optimal solution:
      $$\min \mathbf{x}^T A\mathbf{y}$$

$$\begin{gathered}\text{subject to} : \mathbf{x} = [x_i] \in \mathbb{R}^m, \mathbf{y} = [y_j] \in \mathbb{R}^n \\ \mathbf{x} \geq 0, \mathbf{y} \geq 0 \\ \prod_{i=1}^{m} (x_i)^{r_i} = \prod_{j=1}^{n} (y_j)^{c_j} = 1.\end{gathered}$$

A standard algorithm for approximating a scaling of a matrix to one that has prescribed row- and column-sums (when one exists) is to iteratively scale rows and columns separately so as to achieve corresponding line-sums.

(b) Suppose $\mathbf{1}^T\mathbf{r} = \mathbf{1}^T\mathbf{r}$ and $\bar{\mathbf{x}} = [\bar{x}_i]$ and $\bar{\mathbf{y}} = [\bar{\mathbf{y}}_j]$ form an optimal solution of the optimization problem of Fact 1(d). Let $\bar{\lambda} \equiv \frac{\bar{\mathbf{x}}^T A \bar{\mathbf{y}}}{\mathbf{1}^T\mathbf{r}}$ and let $\bar{X} \in \mathbb{R}^{m \times m}$ and $\bar{Y} \in \mathbb{R}^{n \times n}$ be the diagonal matrices having diagonal elements $\bar{X}_{ii} = \frac{\bar{x}_i}{\bar{\lambda}}$ and $\bar{Y}_{jj} = \bar{y}_j$. Then $B \equiv \bar{X} A \bar{Y}$ is a scaling of A satisfying $B\mathbf{1} = \mathbf{r}$ and $\mathbf{1}^T B = \mathbf{c}^T$.

(c) Suppose $\bar{X} \in \mathbb{R}^{m \times m}$ and $\bar{Y} \in \mathbb{R}^{n \times n}$ are diagonal matrices such that $B \equiv \bar{X} A \bar{Y}$ is a scaling of A satisfying $B\mathbf{1} = \mathbf{r}$ and $\mathbf{1}^T B = \mathbf{c}^T$. Then $\mathbf{1}^T\mathbf{r} = \mathbf{1}^T\mathbf{r}$ and with

$$\bar{\lambda} \equiv \prod_{i=1}^{m} (\bar{X}_{ii})^{-r_i/\mathbf{1}^T\mathbf{r}}$$

and

$$\bar{\mu} \equiv \prod_{i=1}^{m} (\bar{Y}_{jj})^{-c_j/\mathbf{1}^T\mathbf{c}},$$

the vectors $\bar{\mathbf{x}} = [\bar{x}_i] \in \mathbb{R}^m$ and $\bar{\mathbf{y}} = [\bar{y}_j] \in \mathbb{R}^n$ with $\bar{x}_i = \bar{\lambda} X_{ii}$ for $i = 1, \ldots, m$ and $\bar{y}_j = \bar{\mu} Y_{jj}$ for $j = 1, \ldots, n$ are optimal for the optimization problem of Fact 1(d).

2. (*Approximate Prescribed-Line-Sum Scalings*) [RoSc89] Let $A = [a_{ij}] \in \mathbb{R}^{m \times n}$ be a nonnegative matrix, and let $\mathbf{r} = [r_i] \in \mathbb{R}^m$ and $\mathbf{c} = [c_j] \in \mathbb{R}^n$ be positive vectors.

(a) The following are equivalent:

i. For every $\epsilon > 0$ there exists a scaling B of A with $\|B\mathbf{1} - \mathbf{r}\|_1 \leq \epsilon$ and $\|\mathbf{1}^T B - \mathbf{c}^T\|_1 \leq \epsilon$.

ii. There exists nonnegative $m \times n$ matrix $A' = [a'_{ij}]$ with Struct(A') $\subseteq$Struct(A) and $a'_{ij} = a_{ij}$ for each $ij \in$ Struct(A') such that A' has a scaling B satisfying $B\mathbf{1} = \mathbf{r}$ and $\mathbf{1}^T B = \mathbf{c}^T$.

iii. For every $\epsilon > 0$ there exists a matrix B having the same support as A and satisfying $\|B\mathbf{1} - \mathbf{r}\|_1 \leq \epsilon$ and $\|\mathbf{1}^T B - \mathbf{c}^T\|_1 \leq \epsilon$.

iv. There exists a matrix B satisfying Struct$(B) \subseteq$ Struct(A), $B\mathbf{1} = \mathbf{r}$ and $\mathbf{1}^T B = \mathbf{c}^T$.

v. For every $I \subseteq \{1, \ldots, m\}$ and $J \subseteq \{1, \ldots, m\}$ for which $A[I^c, J] = 0$,

$$\sum_{i \in I} r_i \geq \sum_{j \in j} c_j.$$

vi. $\mathbf{1}^T\mathbf{r} = \mathbf{1}^T\mathbf{r}$ and the objective of the optimization problem of Fact 2(a)iii is bounded away from zero.

See [NR99] for a reduction of the problem of finding a scaling of A that satisfies $\|B\mathbf{1} - \mathbf{r}\|_1 \leq \epsilon$ and $\|\mathbf{1}^T B - \mathbf{c}^T\|_1 \leq \epsilon$ for a given $\epsilon > 0$ to the approximate solution of geometric program that is similar to the one in Fact 1(a)iv and for the description of an (ellipsoid) algorithm that solves the latter with complexity bound of $O(1)(m + n)^4 \ln[2 + \frac{mn\sqrt{m^3+n^3}\ln(mn\beta)}{\epsilon^3}]$, where β is the ratio between the largest and smallest positive entries of A.

10.7 Miscellaneous Topics

In this section, we mention several important topics about nonnegative matrices that are not covered in detail in the current chapter due to size constraint; some relevant material appears in other chapters.

Nonnegative Factorization and Completely Positive Matrices

A *nonnegative factorization* of a nonnegative matrix $A \in R^{m\times n}$ is a representation $A = LR$ of A with L and R as nonnegative matrices. The *nonnegative rank* of A is the smallest number of columns of L (rows of R) in such a factorization.

A square matrix A is *doubly nonnegative* if it is nonnegative and positive semidefinite. Such a matrix A is *completely positive* if it has a nonnegative factorization $A = BB^T$; the *CP-rank* of A is then the smallest number of columns of a matrix B in such a factorization.

Facts about nonnegative factorizations and completely positive matrices can be found in [CR93], [BSM03], and [CP05].

The Inverse Eigenvalue Problem The *inverse eigenvalue problem* concerns the identification of necessary conditions and sufficient conditions for a finite set of complex numbers to be the spectrum of a nonnegative matrix.

Facts about the inverse eigenvalue problem can be found in [BP94, Sects. 4.2 and 11.2] and Chapter 28.

Nonhomogenous Products of Matrices A *nonhomogenous product* of nonnegative matrices is the finite matrix product of nonnegative matrices $P_1P_2\dots P_m$, generalizing powers of matrices where the multiplicands are equal (i.e., $P_1 = P_2 = \cdots = P_m$); the study of such products focuses on the case where the multiplicands are taken from a prescribed set.

Facts about Perron–Frobenius type properties of nonhomogenous products of matrices can be found in [Sen81] and [Har02].

Operators Determined by Sets of Nonnegative Matrices in Product Form A finite set of nonnegative $n \times n$ matrices $\{P_\delta : \delta \in \Delta\}$ is said to be in *product form* if there exists finite sets of row vectors $\Delta_1,\dots,\Delta_n$ such that $\Delta = \prod_{i=1}^{n}\Delta_i$ and for each $\delta = (\delta_1,\dots,\delta_n) \in \Delta$, P_δ is the matrix whose rows are, respectively, $\delta_1,\dots,\delta_n$. Such a family determines the *operators* $P_\Delta^{\max}$ and $P_\Delta^{\min}$ on $\mathbb{R}^n$ with $P_\Delta^{\max}x = \max_{\delta\in\Delta} P_\delta x$ and $P_\Delta^{\min}x = \min_{\delta\in\Delta} P_\delta x$ for each $x \in \mathbb{R}^n$.

Facts about Perron–Frobenius-type properties of the operators corresponding to families of matrices in product form can be found in [Zij82], [Zij84], and [RW82].

Max Algebra over Nonnegative Matrices Matrix operations under the max algebra are executed with the max operator replacing (real) addition and (real) addition replacing (real) multiplication.

Perron–Frobenius-type results and scaling results are available for nonnegative matrices when considered as operators under the max algebra; see [RSS94], [Bap98], [But03], [BS05], and Chapter 35.

11.1 Submatrices and Block Matrices

Definitions:

Let $A \in F^{m\times n}$. Then the row indices of A are $\{1, \dots, m\}$, and the column indices of A are $\{1, \dots, n\}$. Let α, β be nonempty sets of indices with $\alpha \subseteq \{1, \dots, m\}$ and $\beta \subseteq \{1, \dots, n\}$.

A **submatrix** $A[\alpha, \beta]$ is a matrix whose rows have indices α among the row indices of A, and whose columns have indices β among the column indices of A. $A(\alpha, \beta) = A[\alpha^c, \beta^c]$, where α^c is the complement of α.

A **principal submatrix** is a submatrix $A[\alpha, \alpha]$, denoted more compactly as $A[\alpha]$.

Let the set $\{1, \dots m\}$ be partitioned into the subsets $\alpha_1, \dots, \alpha_r$ in the usual sense of partitioning a set (so that $\alpha_i \cap \alpha_j = \emptyset$, for all $i \neq j$, $1 \leq i, j \leq r$, and $\alpha_1 \cup \cdots \cup \alpha_r = \{1, \dots, m\}$), and let $\{1, \dots, n\}$ be partitioned into the subsets $\beta_1, \dots, \beta_s$.

The matrix $A \in F^{m\times n}$ is said to be **partitioned** into the submatrices $A[\alpha_i, \beta_j]$, $1 \leq i \leq r$, $1 \leq j \leq s$.

A **block matrix** is a matrix that is partitioned into submatrices $A[\alpha_i, \beta_j]$ with the row indices $\{1, \dots, m\}$ and column indices $\{1, \dots, n\}$ partitioned into subsets sequentially, i.e., $\alpha_1 = \{1, \dots, i_1\}, \alpha_2 = \{i_1 + 1, \dots, i_2\}$, etc.

Each entry of a block matrix, which is a submatrix $A[\alpha_i, \beta_j]$, is called a **block**, and we will sometimes write $A = [A_{ij}]$ to label the blocks, where $A_{ij} = A[\alpha_i, \beta_j]$.

If the block matrix $A \in F^{m\times p}$ is partitioned with α_is and β_js, $1 \leq i \leq r$, $1 \leq j \leq s$, and the block matrix $B \in F^{p\times n}$ is partitioned with β_js and γ_ks, $1 \leq j \leq s$, $1 \leq k \leq t$, then the partitions of A and B are said to be **conformal** (or sometimes **conformable**).

Facts:

The following facts can be found in [HJ85]. This information is also available in many other standard references such as [LT85] or [Mey00].

1. Two block matrices $A = [A_{ij}]$ and $B = [B_{ij}]$ in $F^{m\times n}$, which are both partitioned with the same α_is and β_js, $1 \leq i \leq r$, $1 \leq j \leq s$, may be added block-wise, as with the usual matrix addition, so that the (i, j) block entry of $A+B$ is $(A+B)_{ij} = A_{ij} + B_{ij}$.

2. If the block matrix $A \in F^{m\times p}$ and the block matrix $B \in F^{p\times n}$ have conformal partitions, then we can think of A and B as having entries, which are blocks, so that we can then multiply A and B block-wise to form the $m \times n$ block matrix $C = AB$. Then $C_{ik} = \sum_{j=1}^{s} A_{ij}B_{jk}$, and the matrix C will be partitioned with the α_is and γ_ks, $1 \le i \le r$, $1 \le k \le t$, where A is partitioned with α_is and β_js, $1 \le i \le r$, $1 \le j \le s$, and B is partitioned with β_js and γ_ks, $1 \le j \le s$, $1 \le k \le t$.
3. With addition and multiplication of block matrices described as in Facts 1 and 2, the usual properties of associativity of addition and multiplication of block matrices hold, as does distributivity, and commutativity of addition. The additive identity $\mathbf{0}$ and multiplicative identity I are the same under block addition and multiplication, as with the usual matrix addition and multiplication. The additive identity $\mathbf{0}$ has zero matrices as blocks; the multiplicative identity I has multiplicative identity submatrices as diagonal blocks and zero matrices as off-diagonal blocks.
4. If the partitions of A and B are conformal, the partitions of B and A are not necessarily conformal, even if BA is defined.
5. Let $A \in F^{n\times n}$ be a block matrix of the form $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & \mathbf{0} \end{bmatrix}$, where A_{12} is $k \times k$, and A_{21} is $(n-k) \times (n-k)$. Then $\det(A) = (-1)^{(n+1)k}\det(A_{12})\det(A_{21})$.

Examples:

1. Let the block matrix $A \in \mathbb{C}^{n\times n}$ given by $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$ be Hermitian. Then A_{11} and A_{22} are Hermitian, and $A_{21} = A_{12}^*$.
2. If $A = [a_{ij}]$, then $A[\{i\},\{j\}]$ is the 1×1 matrix whose entry is a_{ij}. The submatrix $A(\{i\},\{j\})$ is the submatrix of A obtained by deleting row i and column j of A.

   Let $A = \begin{bmatrix} 1 & -2 & 5 & 3 & -1 \\ -3 & 0 & 1 & 6 & 1 \\ 2 & 7 & 4 & 5 & -7 \end{bmatrix}$.
3. Then $A[\{2\},\{3\}] = [a_{23}] = [1]$ and $A(\{2\},\{3\}) \begin{bmatrix} 1 & -2 & 3 & -1 \\ 2 & 7 & 5 & -7 \end{bmatrix}$.
4. Let $\alpha = \{1,3\}$ and $\beta = \{1,2,4\}$. Then the submatrix $A[\alpha,\beta] = \begin{bmatrix} 1 & -2 & 3 \\ 2 & 7 & 5 \end{bmatrix}$, and the principal submatrix $A[\alpha] = \begin{bmatrix} 1 & 5 \\ 2 & 4 \end{bmatrix}$.
5. Let $\alpha_1 = \{1\}$, $\alpha_2 = \{2,3\}$ and let $\beta_1 = \{1,2\}$, $\beta_2 = \{3\}$, $\beta_3 = \{4,5\}$. Then the block matrix, with (i,j) block entry $A_{ij} = A[\alpha_i,\beta_j]$, $1 \le i \le 2$, $1 \le j \le 3$, is

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \end{bmatrix} = \left[\begin{array}{rr|r|rr} 1 & -2 & 5 & 3 & -1 \\ \hdashline -3 & 0 & 1 & 6 & 1 \\ 2 & 7 & 4 & 5 & -7 \end{array}\right].$$

6. Let $B = \begin{bmatrix} B_{11} & B_{12} & B_{13} \\ B_{21} & B_{22} & B_{23} \end{bmatrix} = \left[\begin{array}{rr|r|rr} 2 & -1 & 0 & 6 & -2 \\ \hdashline -4 & 0 & 5 & 3 & 7 \\ 1 & 1 & -2 & 2 & 6 \end{array}\right]$. Then the matrices A (of Example 5) and B are partitioned with the same α_is and β_js, so they can be added block-wise:

$$\begin{bmatrix}A_{11}&A_{12}&A_{13}\\A_{21}&A_{22}&A_{23}\end{bmatrix}+\begin{bmatrix}B_{11}&B_{12}&B_{13}\\B_{21}&B_{22}&B_{23}\end{bmatrix}=\begin{bmatrix}A_{11}+B_{11}&A_{12}+B_{12}&A_{13}+B_{13}\\A_{21}+B_{21}&A_{22}+B_{22}&A_{23}+B_{23}\end{bmatrix}$$

$$=\left[\begin{array}{cc|c|cc}3&-3&5&9&-3\\\hline -7&0&6&9&8\\3&8&2&7&-1\end{array}\right].$$

7. The block matrices $A=\begin{bmatrix}A_{11}&A_{12}&A_{13}\\A_{21}&A_{22}&A_{13}\end{bmatrix}$ and $B=\begin{bmatrix}B_{11}\\B_{21}\\B_{31}\end{bmatrix}$ have conformal partitions if the β_j index sets, which form the submatrices $A_{ij}=A[\alpha_i,\beta_j]$ of A, are the same as the β_j index sets, which form the submatrices $B_{jk}=B[\beta_j,\gamma_k]$ of B. For instance, the matrix

$$A=\begin{bmatrix}A_{11}&A_{12}&A_{13}\\A_{21}&A_{22}&A_{23}\end{bmatrix}=\left[\begin{array}{cc|c|cc}1&-2&5&3&-1\\\hline -3&0&1&6&1\\2&7&4&5&-7\end{array}\right]$$

and the matrix $B=\begin{bmatrix}B_{11}\\B_{21}\\B_{31}\end{bmatrix}=\left[\begin{array}{cc}4&-1\\3&9\\\hline 5&2\\\hline 2&-8\\7&-1\end{array}\right]$ have conformal partitions, so A and B can be multiplied block-wise to form the 3×2 matrix

$$AB=\begin{bmatrix}A_{11}B_{11}+A_{12}B_{21}+A_{13}B_{31}\\A_{21}B_{11}+A_{22}B_{21}+A_{23}B_{31}\end{bmatrix}$$

$$=\begin{bmatrix}[1\ \ -2]\begin{bmatrix}4&-1\\3&9\end{bmatrix}+5[5\ \ 2]+[3\ \ -1]\begin{bmatrix}2&-8\\7&-1\end{bmatrix}\\ \begin{bmatrix}-3&0\\2&7\end{bmatrix}\begin{bmatrix}4&-1\\3&9\end{bmatrix}+\begin{bmatrix}1\\4\end{bmatrix}[5\ \ 2]+\begin{bmatrix}6&1\\5&-7\end{bmatrix}\begin{bmatrix}2&-8\\7&-1\end{bmatrix}\end{bmatrix}$$

$$=\begin{bmatrix}[-2\ \ -19]+[25\ \ 10]+[-1\ \ -23]\\ \begin{bmatrix}-12&3\\29&61\end{bmatrix}+\begin{bmatrix}5&2\\20&8\end{bmatrix}+\begin{bmatrix}19&-49\\-39&-33\end{bmatrix}\end{bmatrix}=\begin{bmatrix}22&-32\\12&-44\\10&36\end{bmatrix}.$$

8. Let $A=\left[\begin{array}{cc|c}1&2&3\\4&5&6\end{array}\right]$ and $B=\left[\begin{array}{c|c}7&8\\9&0\\\hline 1&2\end{array}\right]$. Then A and B have conformal partitions. BA is defined, but B and A do not have conformal partitions.

11.2 Block Diagonal and Block Triangular Matrices

Definitions:

A matrix $A = [a_{ij}] \in F^{n\times n}$ is **diagonal** if $a_{ij} = 0$, for all $i \neq j$, $1 \leq i, j \leq n$.

A diagonal matrix $A = [a_{ij}] \in F^{n\times n}$ is said to be **scalar** if $a_{ii} = a$, for all i, $1 \leq i \leq n$, and some scalar $a \in F$, i.e., $A = aI_n$.

A matrix $A \in F^{n\times n}$ is **block diagonal** if A as a block matrix is partitioned into submatrices $A_{ij} \in F^{n_i\times n_j}$, so that $A = [A_{ij}]$, $\sum_{i=1}^{k} n_i = n$, and $A_{ij} = \mathbf{0}$, for all $i \neq j$, $1 \leq i, j \leq k$. Thus, $A = \begin{bmatrix} A_{11} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & A_{22} & \cdots & \mathbf{0} \\ \vdots & & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & A_{kk} \end{bmatrix}$. This block diagonal matrix A is denoted $A = \operatorname{diag}(A_{11}, \ldots, A_{kk})$, where A_{ii} is $n_i \times n_i$, (or sometimes denoted $A = A_{11} \oplus \cdots \oplus A_{kk}$, and called the **direct sum** of $A_{11}, \ldots, A_{kk}$).

A matrix $A = [a_{ij}] \in F^{n\times n}$ is **upper triangular** if $a_{ij} = 0$ for all $i > j, 1 \leq i, j \leq n$.

An upper triangular matrix $A = [a_{ij}] \in F^{n\times n}$ is **strictly upper triangular** if $a_{ij} = 0$ for all $i \geq j$, $1 \leq i, j \leq n$.

A matrix $A \in F^{n\times n}$ is **lower triangular** if $a_{ij} = 0$ for all $i < j$, $1 \leq i, j \leq n$, i.e., if A^T is upper triangular.

A matrix $A \in F^{n\times n}$ is **strictly lower triangular** if A^T is strictly upper triangular.

A matrix is **triangular** if it is upper or lower triangular.

A matrix $A \in F^{n\times n}$ is **block upper triangular** if A as a block matrix is partitioned into the submatrices $A_{ij} \in F^{n_i\times n_j}$, so that $A = [A_{ij}]$, $\sum_{i=1}^{k} n_i = n$, and $A_{ij} = \mathbf{0}$, for all $i > j$, $1 \leq i, j \leq k$, i.e., considering the A_{ij} blocks as the entries of A, A is upper triangular. Thus, $A = \begin{bmatrix} A_{11} & A_{12} & \cdots & A_{1k} \\ \mathbf{0} & A_{22} & \cdots & A_{2k} \\ \vdots & & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & A_{kk} \end{bmatrix}$, where each A_{ij} is $n_i \times n_j$, and $\sum_{i=1}^{k} n_i = n$. The matrix A is **strictly block upper triangular** if $A_{ij} = \mathbf{0}$ for all $i \geq j$, $1 \leq i, j \leq k$.

A matrix $A \in F^{n\times n}$ is **block lower triangular** if A^T is block upper triangular.

A matrix $A \in F^{n\times n}$ is **strictly block lower triangular** if A^T is strictly block upper triangular.

A matrix $A = [a_{ij}] \in F^{n\times n}$ is **upper Hessenberg** if $a_{ij} = 0$ for all $i - 2 \geq j$, $1 \leq i, j \leq n$, i.e., A has the form

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n-1} & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n-1} & a_{2n} \\ 0 & a_{32} & a_{33} & \cdots & a_{3n-1} & a_{3n} \\ \vdots & \vdots & \ddots & \ddots & & \vdots \\ 0 & 0 & \cdots & a_{n-1n-2} & a_{n-1n-1} & a_{n-1n} \\ 0 & 0 & \cdots & 0 & a_{nn-1} & a_{nn} \end{bmatrix}.$$

A matrix $A = [a_{ij}] \in F^{n\times n}$ is **lower Hessenberg** if A^T is upper Hessenberg.

Facts:

The following facts can be found in [HJ85]. This information is also available in many other standard references such as [LT85] or [Mey00].

1. Let $D, D' \in F^{n\times n}$ be any diagonal matrices. Then $D+D'$ and DD' are diagonal, and $DD' = D'D$. If $D = \operatorname{diag}(d_1, \ldots, d_n)$ is nonsingular, then $D^{-1} = \operatorname{diag}(1/d_1, \ldots, 1/d_n)$.
2. Let $D \in F^{n\times n}$ be a matrix such that $DA = AD$ for all $A \in F^{n\times n}$. Then D is a scalar matrix.
3. If $A \in F^{n\times n}$ is a block diagonal matrix, so that $A = \operatorname{diag}(A_{11}, \ldots, A_{kk})$, then $\operatorname{tr}(A) = \sum_{i=1}^{k} \operatorname{tr}(A_{ii})$, $\det(A) = \Pi_{i=1}^{k}\det(A_{ii})$, $\operatorname{rank}(A) = \sum_{i=1}^{k} \operatorname{rank}(A_{ii})$, and $\sigma(A) = \sigma(A_{11}) \cup \cdots \cup \sigma(A_{kk})$.
4. Let $A \in F^{n\times n}$ be a block diagonal matrix, so that $A = \operatorname{diag}(A_{11}, A_{22} \ldots, A_{kk})$. Then A is nonsingular if and only if A_{ii} is nonsingular for each i, $1 \le i \le k$. Moreover, $A^{-1} = \operatorname{diag}(A_{11}^{-1}, A_{22}^{-1} \ldots, A_{kk}^{-1})$.
5. See Section 4.4 for information on diagonalizability of matrices.
6. Let $A \in F^{n\times n}$ be a block diagonal matrix, so that $A = \operatorname{diag}(A_{11}, \ldots, A_{kk})$. Then A is diagonalizable if and only if A_{ii} is diagonalizable for each i, $1 \le i \le k$.
7. If $A, B \in F^{n\times n}$ are upper (lower) triangular matrices, then $A+B$ and AB are upper (lower) triangular. If the upper (lower) triangular matrix $A = [a_{ij}]$ is nonsingular, then A^{-1} is upper (lower) triangular with diagonal entries $1/a_{11}, \ldots, 1/a_{nn}$.
8. Let $A \in F^{n\times n}$ be block upper triangular, so that $A = \begin{bmatrix} A_{11} & A_{12} & \cdots & A_{1k} \\ \mathbf{0} & A_{22} & \cdots & A_{2k} \\ \vdots & & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & A_{kk} \end{bmatrix}$.

   Then $\operatorname{tr}(A) = \sum_{i=1}^{k} \operatorname{tr}(A_{ii})$, $\det(A) = \Pi_{i=1}^{k}\det(A_{ii})$, $\operatorname{rank}(A) \ge \sum_{i=1}^{k} \operatorname{rank}(A_{ii})$, and $\sigma(A) = \sigma(A_{11}) \cup \cdots \cup \sigma(A_{kk})$.
9. Let $A = (A_{ij}) \in F^{n\times n}$ be a block triangular matrix (either upper or lower triangular). Then A is nonsingular if and only if A_{ii} is nonsingular for each i, $1 \le i \le k$. Moreover, the $n_i \times n_i$ diagonal block entries of A^{-1} are A_{ii}^{-1}, for each i, $1 \le i \le k$.
10. *Schur's Triangularization Theorem:* Let $A \in \mathbb{C}^{n\times n}$. Then there is a unitary matrix $U \in \mathbb{C}^{n\times n}$ so that U^*AU is upper triangular. The diagonal entries of U^*AU are the eigenvalues of A.
11. Let $A \in \mathbb{R}^{n\times n}$. Then there is an orthogonal matrix $V \in \mathbb{R}^{n\times n}$ so that V^TAV is of upper Hessenberg form $\begin{bmatrix} A_{11} & A_{12} & \cdots & A_{1k} \\ \mathbf{0} & A_{22} & \cdots & A_{2k} \\ \vdots & & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & A_{kk} \end{bmatrix}$, where each A_{ii}, $1 \le i \le k$, is 1×1 or 2×2. Moreover, when A_{ii} is 1×1, the entry of A_{ii} is an eigenvalue of A, whereas when A_{ii} is 2×2, then A_{ii} has two eigenvalues which are nonreal complex conjugates of each other, and are eigenvalues of A.
12. (For more information on unitary triangularization, see Section 8.2.)
13. Let $A = [A_{ij}] \in F^{n\times n}$ with $|\sigma(A)| = n$, where $\lambda_1, \ldots, \lambda_k \in \sigma(A)$ are the distinct eigenvalues of A. Then there is a nonsingular matrix $T \in F^{n\times n}$ so that $T^{-1}AT = \operatorname{diag}(A_{11}, \ldots, A_{kk})$, where each $A_{ii} \in F^{n_i\times n_i}$ is upper triangular with all diagonal entries of A_{ii} equal to λ_i, for $1 \le i \le k$ (and $\sum_{i=1}^{k} n_i = n$).
14. Let $A \in F^{n\times n}$ be a block upper triangular matrix, of the form $A = \begin{bmatrix} A_{11} & A_{12} \\ \mathbf{0} & A_{22} \end{bmatrix}$, where A_{ij} is $n_i \times n_j$, $1 \le i,j \le 2$, and $\sum_{i=1}^{2} n_i = n$. (Note that any block upper triangular matrix can be said to have this form.) Let $\mathbf{x}$ be an eigenvector of A_{11}, with

corresponding eigenvalue λ, so that $A_{11}\mathbf{x} = \lambda\mathbf{x}$, where $\mathbf{x}$ is a (column) vector with n_1 components. Then the (column) vector with n components $\begin{bmatrix}\mathbf{x}\\ \mathbf{0}\end{bmatrix}$ is an eigenvector of A with eigenvalue λ. Let $\mathbf{y}$ be a left eigenvector of A_{22}, with corresponding eigenvalue μ, so that $\mathbf{y}A_{22} = \mathbf{y}\mu$, where $\mathbf{y}$ is a row vector with n_2 components. Then the (row) vector with n components $[\mathbf{0}\;\; \mathbf{y}]$ is a left eigenvector of A with eigenvalue μ.

Examples:

1. The matrix $A = \begin{bmatrix} 1 & 3 & 0 & 0 & 0\\ 2 & 4 & 0 & 0 & 0\\ 0 & 0 & 5 & 0 & 0\\ 0 & 0 & 0 & 6 & 8\\ 0 & 0 & 0 & 7 & 9\end{bmatrix}$ is a block diagonal matrix, and the trace, determinant, and rank can be calculated block-wise, where $A_{11} = \begin{bmatrix}1 & 3\\ 2 & 4\end{bmatrix}$, $A_{22} = [5]$, and $A_{33} = \begin{bmatrix}6 & 8\\ 7 & 9\end{bmatrix}$, as $\operatorname{tr}(A) = 25 = \sum_{i=1}^{3}\operatorname{tr}(A_{ii})$, $\det(A) = (-2)(5)(-2) = \Pi_{i=1}^{3}\det(A_{ii})$, and $\operatorname{rank}(A) = 5 = \sum_{i=1}^{3}\operatorname{rank}(A_{ii})$.
2. Let $A = \begin{bmatrix} a & b & c\\ 0 & d & e\\ 0 & 0 & f\end{bmatrix} \in F^{3\times 3}$, an upper triangular matrix. If a, d, f are nonzero, then
$$A^{-1} = \begin{bmatrix} \frac{1}{a} & -\frac{b}{ad} & \frac{be-cd}{adf}\\ 0 & \frac{1}{d} & -\frac{e}{df}\\ 0 & 0 & \frac{1}{f}\end{bmatrix}.$$
3. The matrix $B = \begin{bmatrix} 1 & 3 & 0 & 0 & 0\\ 2 & 4 & 5 & 0 & 0\\ 0 & 0 & 0 & 6 & 0\\ 0 & 0 & 0 & 0 & 7\\ 0 & 0 & 0 & 0 & 8\end{bmatrix}$ is not block diagonal. However, B is block upper triangular, with $B_{11} = \begin{bmatrix}1 & 3\\ 2 & 4\end{bmatrix}$, $B_{22} = [0]$, $B_{33} = \begin{bmatrix}0 & 7\\ 0 & 8\end{bmatrix}$, $B_{12} = \begin{bmatrix}0\\ 5\end{bmatrix}$, $B_{13} = \begin{bmatrix}0 & 0\\ 0 & 0\end{bmatrix}$, and $B_{23} = \begin{bmatrix}6 & 0\end{bmatrix}$. Notice that $4 = \operatorname{rank}(B) \geq \sum_{i=1}^{3}\operatorname{rank}(B_{ii}) = 2 + 0 + 1 = 3$.
4. The 4×4 matrix $\begin{bmatrix} 1 & 2 & 0 & 0\\ 3 & 4 & 5 & 0\\ 6 & 7 & 8 & 9\\ 10 & 11 & 12 & 13\end{bmatrix}$ is not lower triangular, but is lower Hessenberg.

11.3 Schur Complements

In this subsection, the square matrix $A = \begin{bmatrix}A_{11} & A_{12}\\ A_{21} & A_{22}\end{bmatrix}$ is partitioned as a block matrix, where A_{11} is nonsingular.

Definitions:

The **Schur complement** of A_{11} in A is the matrix $A_{22} - A_{21}A_{11}^{-1}A_{12}$, sometimes denoted A/A_{11}.

Facts:

1. [Zha99] $\begin{bmatrix} I & \mathbf{0} \\ -A_{21}A_{11}^{-1} & I \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} I & -A_{11}^{-1}A_{12} \\ \mathbf{0} & I \end{bmatrix} = \begin{bmatrix} A_{11} & \mathbf{0} \\ \mathbf{0} & A/A_{11} \end{bmatrix}$.
2. [Zha99] Let $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$, where A_{11} is nonsingular. Then $\det(A) = \det(A_{11})\det(A/A_{11})$. Also, $\operatorname{rank}(A) = \operatorname{rank}(A_{11}) + \operatorname{rank}(A/A_{11})$.
3. [Zha99] Let $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$. Then A is nonsingular if and only if both A_{11} and the Schur complement of A_{11} in A are nonsingular.
4. [HJ85] Let $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$, where A_{11}, A_{22}, A/A_{11}, A/A_{22}, and A are nonsingular. Then $A^{-1} = \begin{bmatrix} (A/A_{22})^{-1} & -A_{11}^{-1}A_{12}(A/A_{11})^{-1} \\ -A_{22}^{-1}A_{21}(A/A_{22})^{-1} & (A/A_{11})^{-1} \end{bmatrix}$.
5. [Zha99] Let $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$, where A_{11}, A_{22}, A/A_{11}, and A/A_{22} are nonsingular. An equation relating the Schur complements of A_{11} in A and A_{22} in A is $(A/A_{22})^{-1} = A_{11}^{-1} + A_{11}^{-1}A_{12}(A/A_{11})^{-1}A_{21}A_{11}^{-1}$.
6. [LT85] Let $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$, where the $k \times k$ matrix A_{11} is nonsingular. Then $\operatorname{rank}(A) = k$ if and only if $A/A_{11} = \mathbf{0}$.
7. [Hay68] Let $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{12}^* & A_{22} \end{bmatrix}$ be Hermitian, where A_{11} is nonsingular. Then the inertia of A is $\operatorname{in}(A) = \operatorname{in}(A_{11}) + \operatorname{in}(A/A_{11})$.
8. [Hay68] Let $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{12}^* & A_{22} \end{bmatrix}$ be Hermitian, where A_{11} is nonsingular. Then A is positive (semi)definite if and only if both A_{11} and A/A_{11} are positive (semi)definite.

Examples:

1. Let $A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 10 \end{bmatrix}$. Then with $A_{11} = 1$, we have

$$\begin{bmatrix} 1 & \mathbf{0} \\ -\begin{bmatrix} 4 \\ 7 \end{bmatrix} & I_2 \end{bmatrix} \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 10 \end{bmatrix} \begin{bmatrix} 1 & -[2\ 3] \\ \mathbf{0} & I_2 \end{bmatrix} = \begin{bmatrix} 1 & \mathbf{0} \\ \mathbf{0} & \begin{bmatrix} 5 & 6 \\ 8 & 10 \end{bmatrix} - \begin{bmatrix} 4 \\ 7 \end{bmatrix} 1^{-1} [2\ 3] \end{bmatrix}$$
$$= \begin{bmatrix} 1 & \mathbf{0} \\ \mathbf{0} & \begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix} \end{bmatrix}.$$

2. Let $A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 10 \end{bmatrix}$. With $A_{11} = 1$, and $A_{22} = \begin{bmatrix} 5 & 6 \\ 8 & 10 \end{bmatrix}$, then $A/A_{11} = \begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix}$, $A/A_{22} = 1 - [2\ 3] \begin{bmatrix} 5 & 6 \\ 8 & 10 \end{bmatrix}^{-1} \begin{bmatrix} 4 \\ 7 \end{bmatrix} = -\frac{3}{2}$, and

$$A^{-1} = \begin{bmatrix} \left(-\frac{3}{2}\right)^{-1} & -[2\ 3]\begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix}^{-1} \\ -\begin{bmatrix} 5 & 6 \\ 8 & 10 \end{bmatrix}^{-1}\begin{bmatrix} 4 \\ 7 \end{bmatrix}\left(-\frac{3}{2}\right)^{-1} & \begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix}^{-1} \end{bmatrix}$$

$$= \begin{bmatrix} -\frac{2}{3} & \frac{1}{3}[-4\ \ 3] \\ \begin{bmatrix} -\frac{2}{3} \\ 1 \end{bmatrix} & -\frac{1}{3}\begin{bmatrix} -11 & 6 \\ 6 & -3 \end{bmatrix} \end{bmatrix} = \begin{bmatrix} -\frac{2}{3} & -\frac{4}{3} & 1 \\ -\frac{2}{3} & \frac{11}{3} & -2 \\ 1 & -2 & 1 \end{bmatrix}.$$

3. Let $A \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 10 \end{bmatrix}$.

   Then, from Fact 5,

$$(A/A_{22})^{-1} = \left(-\frac{3}{2}\right)^{-1} = 1^{-1} + 1^{-1}[2\ \ 3]\begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix}^{-1}\begin{bmatrix} 4 \\ 7 \end{bmatrix}1^{-1},$$

$$= A_{11}^{-1} + A_{11}^{-1}A_{12}(A/A_{11})^{-1}A_{21}A_{11}^{-1}.$$

11.4 Kronecker Products

Definitions:

Let $A \in F^{m\times n}$ and $B \in F^{p\times q}$. Then the **Kronecker product** (sometimes called the **tensor product**) of A and B, denoted $A \otimes B$, is the $mp \times nq$ partitioned matrix $A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B & \cdots & a_{1n}B \\ a_{21}B & a_{22}B & \cdots & a_{2n}B \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1}B & a_{n2}B & \cdots & a_{nn}B \end{bmatrix}$.

Let $A \in F^{m\times n}$ and let the jth column of A, namely, $A[\{1,\ldots,m\},\{j\}]$ be denoted a_j, for $1 \le j \le n$.

The column vector with mn components, denoted vec(A), defined by $\text{vec}(A) = \begin{bmatrix} a_1 \\ a_2 \\ \vdots \\ a_n \end{bmatrix} \in F^{mn}$, is the **vec-function** of A, i.e., vec(A) is formed by stacking the columns of A on top of each other in their natural order.

Facts:

All of the following facts except those for which a specific reference is given can be found in [LT85].

1. Let $A \in F^{m\times n}$ and $B \in F^{p\times q}$. If $a \in F$, then $a(A \otimes B) = (aA) \otimes B = A \otimes (aB)$.
2. Let $A, B \in F^{m\times n}$ and $C \in F^{p\times q}$. Then $(A + B) \otimes C = A \otimes C + B \otimes C$.

3. Let $A \in F^{m\times n}$ and $B, C \in F^{p\times q}$. Then $A \otimes (B + C) = A \otimes B + A \otimes C$.
4. Let $A \in F^{m\times n}$, $B \in F^{p\times q}$, and $C \in F^{r\times s}$. Then $A \otimes (B \otimes C) = (A \otimes B) \otimes C$.
5. Let $A \in F^{m\times n}$ and $B \in F^{p\times q}$. Then $(A \otimes B)^T = A^T \otimes B^T$.
6. [MM64] Let $A \in \mathbb{C}^{m\times n}$ and $B \in \mathbb{C}^{p\times q}$. Then $\overline{(A \otimes B)} = \overline{A} \otimes \overline{B}$.
7. [MM64] Let $A \in \mathbb{C}^{m\times n}$ and $B \in \mathbb{C}^{p\times q}$. Then $(A \otimes B)^* = A^* \otimes B^*$.
8. Let $A \in F^{m\times n}$, $B \in F^{p\times q}$, $C \in F^{n\times r}$, and $D \in F^{q\times s}$. Then $(A \otimes B)(C \otimes D) = AC \otimes BD$.
9. Let $A \in F^{m\times n}$ and $B \in F^{p\times q}$. Then $A \otimes B = (A \otimes I_p)(I_n \otimes B) = (I_m \otimes B)(A \otimes I_q)$.
10. If $A \in F^{m\times m}$ and $B \in F^{n\times n}$ are nonsingular, then $A \otimes B$ is nonsingular and $(A \otimes B)^{-1} = A^{-1} \otimes B^{-1}$.
11. Let $A_1, A_2, \cdots, A_k \in F^{m\times m}$, and $B_1, B_2, \cdots, B_k \in F^{n\times n}$. Then $(A_1 \otimes B_1)(A_2 \otimes B_2)\cdots(A_k \otimes B_k) = (A_1A_2\cdots A_k) \otimes (B_1B_2\cdots B_k)$.
12. Let $A \in F^{m\times m}$ and $B \in F^{n\times n}$. Then $(A \otimes B)^k = A^k \otimes B^k$.
13. If $A \in F^{m\times m}$ and $B \in F^{n\times n}$, then there is an $mn \times mn$ permutation matrix P so that $P^T(A \otimes B)P = B \otimes A$.
14. Let $A, B \in F^{m\times n}$. Then $\mathrm{vec}(aA + bB) = a\ \mathrm{vec}(A) + b\ \mathrm{vec}(B)$, for any $a, b \in F$.
15. If $A \in F^{m\times n}$, $B \in F^{p\times q}$, and $X \in F^{n\times p}$, then $\mathrm{vec}(AXB) = (B^T \otimes A)\mathrm{vec}(X)$.
16. If $A \in F^{m\times m}$ and $B \in F^{n\times n}$, then $\det(A \otimes B) = (\det(A))^n(\det(B))^m$, $\mathrm{tr}(A \otimes B) = (\mathrm{tr}(A))(\mathrm{tr}(B))$, and $\mathrm{rank}(A \otimes B) = (\mathrm{rank}(A))(\mathrm{rank}(B))$.
17. Let $A \in F^{m\times m}$ and $B \in F^{n\times n}$, with $\sigma(A) = \{\lambda_1, \ldots, \lambda_m\}$ and $\sigma(B) = \{\mu_1, \ldots, \mu_n\}$. Then $A \otimes B \in F^{mn\times mn}$ has eigenvalues $\{\lambda_s\mu_t | 1 \le s \le m, 1 \le t \le n\}$. Moreover, if the right eigenvectors of A are denoted $\mathbf{x}_i$, and the right eigenvectors of B are denoted $\mathbf{y}_j$, so that $A\mathbf{x}_i = \lambda_i\mathbf{x}_i$ and $B\mathbf{y}_j = \mu_j\mathbf{y}_j$, then $(A \otimes B)(\mathbf{x}_i \otimes \mathbf{y}_j) = \lambda_i\mu_j(\mathbf{x}_i \otimes \mathbf{y}_j)$.
18. Let $A \in F^{m\times m}$ and $B \in F^{n\times n}$, with $\sigma(A) = \{\lambda_1, \ldots, \lambda_m\}$ and $\sigma(B) = \{\mu_1, \ldots, \mu_n\}$. Then $(I_n \otimes A) + (B \otimes I_m)$ has eigenvalues $\{\lambda_s + \mu_t | 1 \le s \le m, 1 \le t \le n\}$.
19. Let $p(x, y) \in F[x, y]$ so that $p(x, y) = \sum_{i,j=1}^{k} a_{ij}x^iy^j$, where $a_{ij} \in F$, $1 \le i \le k$, $1 \le j \le k$. Let $A \in F^{m\times m}$ and $B \in F^{n\times n}$. Define $p(A; B)$ to be the $mn \times mn$ matrix $p(A; B) = \sum_{i,j=1}^{k} a_{ij}(A^i \otimes B^j)$. If $\sigma(A) = \{\lambda_1, \ldots, \lambda_m\}$ and $\sigma(B) = \{\mu_1, \ldots, \mu_n\}$, then $\sigma(p(A; B)) = \{p(\lambda_s, \mu_t) | 1 \le s \le m, 1 \le t \le n\}$.
20. Let $A_1, A_2 \in F^{m\times m}$, $B_1, B_2 \in F^{n\times n}$. If A_1 and A_2 are similar, and B_1 and B_2 are similar, then $A_1 \otimes B_1$ is similar to $A_2 \otimes B_2$.
21. If $A \in F^{m\times n}$, $B \in F^{p\times q}$, and $X \in F^{n\times p}$, then $\mathrm{vec}(AX) = (I_p \otimes A)\mathrm{vec}(X)$, $\mathrm{vec}(XB) = (B^T \otimes I_n)\mathrm{vec}(X)$, and $\mathrm{vec}(AX + XB) = [(I_p \otimes A) + (B^T \otimes I_n)]\mathrm{vec}(X)$.
22. If $A \in F^{m\times n}$, $B \in F^{p\times q}$, $C \in F^{m\times q}$, and $X \in F^{n\times p}$, then the equation $AXB = C$ can be written in the form $(B^T \otimes A)\mathrm{vec}(X) = \mathrm{vec}(C)$.
23. Let $A \in F^{m\times m}$, $B \in F^{n\times n}$, $C \in F^{m\times n}$, and $X \in F^{m\times n}$. Then the equation $AX + XB = C$ can be written in the form $[(I_n \otimes A) + (B^T \otimes I_m)]\mathrm{vec}(X) = \mathrm{vec}(C)$.
24. Let $A \in \mathbb{C}^{m\times m}$ and $B \in \mathbb{C}^{n\times n}$ be Hermitian. Then $A \otimes B$ is Hermitian.
25. Let $A \in \mathbb{C}^{m\times m}$ and $B \in \mathbb{C}^{n\times n}$ be positive definite. Then $A \otimes B$ is positive definite.

Examples:

1. Let $A = \begin{bmatrix} 1 & -1 \\ 0 & 2 \end{bmatrix}$ and $B = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix}$. Then $A \otimes B = \begin{bmatrix} 1 & 2 & 3 & -1 & -2 & -3 \\ 4 & 5 & 6 & -4 & -5 & -6 \\ 7 & 8 & 9 & -7 & -8 & -9 \\ 0 & 0 & 0 & 2 & 4 & 6 \\ 0 & 0 & 0 & 8 & 10 & 12 \\ 0 & 0 & 0 & 14 & 16 & 18 \end{bmatrix}$.

2. Let $A = \begin{bmatrix} 1 & -1 \\ 0 & 2 \end{bmatrix}$. Then $\mathrm{vec}(A) = \begin{bmatrix} 1 \\ 0 \\ -1 \\ 2 \end{bmatrix}$.

3. Let $A \in F^{m\times m}$ and $B \in F^{n\times n}$. If A is upper (lower) triangular, then $A \otimes B$ is block upper (lower) triangular. If A is diagonal, then $A \otimes B$ is block diagonal. If both A and B are upper (lower) triangular, then $A \otimes B$ is (upper) triangular. If both A and B are diagonal, then $A \otimes B$ is diagonal.
4. Let $A \in F^{m\times n}$ and $B \in F^{p\times q}$. If $A \otimes B = \mathbf{0}$, then $A = \mathbf{0}$ or $B = \mathbf{0}$.
5. Let $A \in F^{m\times n}$. Then $A \otimes I_n = \begin{bmatrix} a_{11}I_n & a_{12}I_n & \cdots & a_{1n}I_n \\ a_{21}I_n & a_{22}I_n & \cdots & a_{2n}I_n \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1}I_n & a_{n2}I_n & \cdots & a_{mn}I_n \end{bmatrix} \in F^{mn\times n^2}$. Let $B \in F^{p\times p}$.

   Then $I_n \otimes B = \operatorname{diag}(B, B, \ldots, B) \in F^{np\times np}$, and $I_m \otimes I_n = I_{mn}$.

The *Schur complement*, named after Issai Schur (1875–1941), plays an important role as a basic tool in mathematical research and applications, particularly in matrix analysis, statistics, and numerical analysis. It was named and given a notation in 1968 by Emilie Haynsworth (1916–1985). The idea of using the Schur complement technique to deal with linear systems and matrix problems is classical. It was certainly known to James Joseph Sylvester (1814–1897) in 1851 [Syl52], and probably also to Carl Friedrich Gauss (1777–1855) (for Gaussian elimination). A fundamental determinant identity presented by Schur in 1917 [Sch17] was referred to as the *formula of Schur* by Felix R. Gantmacher (1908–1964) [Gan98, p. 46]. Our goal here is to illuminate the Schur complement by presenting basic facts, results, and examples. A comprehensive survey on the topic, contributed by T. Ando, C. Brezinski, C. R. Johnson, J.-Z. Liu, S. Puntanan, R. L. Smith, G. P. H. Styan, and the present authors, is available in [Zha05].

12.1 Introduction and Notation

Our matrices are real or complex, though greater algebraic generality is often possible. Let $\mathbb{C}^{m\times n}$ be the collection of all $m \times n$ complex (including real) matrices.

Definitions:

For index sets $\alpha \subseteq \{1,\dots,m\}$ and $\beta \subseteq \{1,\dots,n\}$, we denote by $A[\alpha,\beta]$ the submatrix of A with row indices in α and column indices in β, and by $A(\alpha,\beta)$ the submatrix of A with row indices not in α and column indices not in β. It is convenient sometimes to write $A(\alpha,\beta) = A[\alpha^c,\beta^c]$, where $\alpha^c = \{1,\dots,m\}\backslash\alpha$ and $\beta^c = \{1,\dots,n\}\backslash\beta$. Thus, $A[\alpha,\beta^c]$ is the submatrix of A with row indices in α and column indices not in β. We often write $A\,[\alpha]$ for $A\,[\alpha,\alpha]$ and $A(\alpha)$ for $A[\alpha^c] = A[\alpha^c,\alpha^c]$. See Chapter 11 for more information about partitioned matrices.

Let $\mathcal{H}_n$ be the collection of all $n \times n$ Hermitian matrices.

A matrix is **positive semidefinite** (**positive definite**) if it is Hermitian and all its eigenvalues are nonnegative (positive).

A matrix A is **negative semidefinite** (**negative definite**) if $-A$ is positive semidefinite (definite).

The **Loewner partial order** on Hermitian matrices

$$A \succeq B \qquad (A \succ B)$$

means that $A - B$ is positive semidefinite (positive definite). See Chapter 9 for more information about positive semidefinite matrices.

We denote the nonincreasingly ordered eigenvalues of $H \in \mathcal{H}_n$ by

$$\lambda_1(H) \geq \cdots \geq \lambda_n(H).$$

The eigenvalues of a Hermitian matrix are necessarily real; see Chapter 9.

Two matrices A and B of the same size are said to be ***congruent** if there is a nonsingular matrix S of the same size such that $A = SAS^*$; *congruence is an equivalence relation. See Chapters 7 and 13 for more information about *congruence.

Examples:

1. Let $A = \begin{bmatrix} 1 & 2 & 3 \\ 0 & i & 4 \end{bmatrix}$. For $\alpha = \{1,2\}$, $\beta = \{2,3\}$, $A[\alpha] = \begin{bmatrix} 1 & 2 \\ 0 & i \end{bmatrix}$, $A[\alpha,\beta] = \begin{bmatrix} 2 & 3 \\ i & 4 \end{bmatrix}$, and $A[\alpha,\beta^c] = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$.
2. Let $A = \begin{bmatrix} 1 & 2 & 3 \\ 0 & i & 4 \end{bmatrix}$. For $\alpha = \{2,3\}$, $\beta = \{1,2\}$, $A^*[\alpha,\beta] = \begin{bmatrix} 2 & -i \\ 3 & 4 \end{bmatrix} = (A[\beta,\alpha])^*$.
3. Let $A = \begin{bmatrix} 2 & -1 \\ -1 & 3 \end{bmatrix}$ and $B = \begin{bmatrix} 0 & i \\ -i & 1 \end{bmatrix}$; both A and B are Hermitian. Then $A - B = \begin{bmatrix} 2 & -1-i \\ -1+i & 2 \end{bmatrix}$ is Hermitian and has eigenvalues $2 \pm \sqrt{2}$, both positive. So $A > B$.
4. Let $H = \begin{bmatrix} 3 & -2 & 4 \\ -2 & 6 & 2 \\ 4 & 2 & 3 \end{bmatrix}$. Then H is Hermitian (real symmetric). The ordered eigenvalues of H are $\lambda_1(H) = 7, \lambda_2(H) = 7, \lambda_3(H) = -2$.

12.2 The Schur Complement

Definitions:

Let A be a given $m \times n$ matrix. Let $\alpha \subseteq \{1,\ldots,m\}$ and $\beta \subseteq \{1,\ldots,n\}$ be index sets.

If $|\alpha| = |\beta|$ and if $A[\alpha,\beta]$ is nonsingular, we define the **Schur complement** of $A[\alpha,\beta]$ in A (also called the *Schur complement of A relative to* $A[\alpha,\beta]$) to be the matrix

$$A\left[\alpha^c,\beta^c\right] - A\left[\alpha^c,\beta\right]\left(A\left[\alpha,\beta\right]\right)^{-1} A\left[\alpha,\beta^c\right] \tag{12.1}$$

and denote it by $A/A[\alpha,\beta]$. When $\alpha = \beta$, we write $A/\alpha = A/A[\alpha]$ for short. The Schur complement of $A[\alpha]$ in A is

$$A(\alpha) - A\left[\alpha^c,\alpha\right]\left(A\left[\alpha\right]\right)^{-1} A\left[\alpha,\alpha^c\right].$$

It is convenient to deal with Schur complements in 2×2 block matrices. Let

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}. \tag{12.2}$$

The **Schur complement** of A_{11} in A (or the *Schur complement of* A *relative to* A_{11}) is

$$A/A_{11} = A_{22} - A_{21}A_{11}^{-1}A_{12}.$$

Likewise, the **Schur complement** of A_{22} in A is

$$A/A_{22} = A_{11} - A_{12}A_{22}^{-1}A_{21}.$$

In addition, if A_{12} and A_{21} are square and nonsingular, then

$$A/A_{12} = A_{21} - A_{22}A_{12}^{-1}A_{11}, \quad A/A_{21} = A_{12} - A_{11}A_{21}^{-1}A_{22}.$$

Facts:

The following facts can be found in Chapters 1 and 4 of [Zha05].

1. Let A be an $m \times n$ matrix. Then $(aA)/\alpha = a(A/\alpha)$ for any $a \in \mathbb{C}$.
2. Let A be an $m \times n$ matrix. Then $(A/\alpha)^* = A^*/\alpha$.
3. If A is an $n \times n$ nonsingular lower (or upper) triangular matrix, then $A/\alpha = A(\alpha)$ for any $\alpha = \{1, \ldots, k\}$ or $\alpha = \{k, \ldots, n\}$, in which $k < n$.
4. Although it can be useful to have the Schur complement in the general form (12.1), it is equivalent to the simpler presentation (12.2): there are permutations of the rows and columns of A that put $A[\alpha, \beta]$ into the upper left corner of A, leaving the rows and columns of $A[\alpha, \beta^c]$ and $A[\alpha^c, \beta]$ in the same increasing order as in A. If A is square and $\alpha = \beta$, the two permutations are the same, so there exists a permutation matrix P such that
$$P^T A P = \begin{bmatrix} A[\alpha] & A[\alpha, \beta^c] \\ A[\alpha^c, \beta] & A(\alpha) \end{bmatrix}.$$
Thus
$$\left(P^T A P\right) / A[\alpha] = A/\alpha.$$
5. Let $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$, where A is square and nonsingular. Then
$$\begin{bmatrix} I & 0 \\ -CA^{-1} & I \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} I & -A^{-1}B \\ 0 & I \end{bmatrix} = \begin{bmatrix} A & 0 \\ 0 & M/A \end{bmatrix}.$$
6. *Schur's determinant formula* for 2×2 block matrices: Let $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$ be a square partitioned matrix, in which A is square and nonsingular. Then
$$\det(M/A) = \det M \,/\, \det A, \quad \text{i.e.,} \quad \det M = \det(M/A)\, \det A.$$
Also, $\operatorname{rank} M = \operatorname{rank} A + \operatorname{rank}(M/A)$. Thus, $\operatorname{rank} M = \operatorname{rank} A$ if and only if $M/A = 0$. When A is nonsingular, M is nonsingular if and only if M/A is nonsingular.
7. *Schur's general determinant formula*: Let A be an n-square matrix and let $\alpha = \{\alpha_1, \ldots, \alpha_k\}$, $\beta = \{\beta_1, \ldots, \beta_k\} \subseteq \{1, \ldots, n\}$. If $A[\alpha, \beta]$ is nonsingular, then
$$\det A = \operatorname{sgn}(\alpha)\operatorname{sgn}(\beta) \det A[\alpha, \beta] \det\left(A/A[\alpha, \beta]\right),$$
in which
$$\operatorname{sgn}(\alpha) = (-1)^{(\sum_{i=1}^{k} \alpha_i) - k(k+1)/2}.$$

8. *Banachiewicz's inversion formula*: Let $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$ be a square partitioned matrix and suppose that both A and M/A are nonsingular. Then M is nonsingular and

$$M^{-1} = \begin{bmatrix} A^{-1} + A^{-1}B\,(M/A)^{-1}\,CA^{-1} & -A^{-1}B\,(M/A)^{-1} \\ -\,(M/A)^{-1}\,CA^{-1} & (M/A)^{-1} \end{bmatrix}.$$

9. Let $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$. Assume that A and D are nonsingular and let

$$S = M/A = D - CA^{-1}B, \quad T = M/D = A - BD^{-1}C.$$

   Then each of the following expressions is equal to M^{-1} if the indicated inverses exist:

   (a) $\begin{bmatrix} A^{-1} + A^{-1}BS^{-1}CA^{-1} & -A^{-1}BS^{-1} \\ -S^{-1}CA^{-1} & S^{-1} \end{bmatrix}$.

   (b) $\begin{bmatrix} T^{-1} & -T^{-1}BD^{-1} \\ -D^{-1}CT^{-1} & D^{-1} + D^{-1}CT^{-1}BD^{-1} \end{bmatrix}$.

   (c) $\begin{bmatrix} T^{-1} & -A^{-1}BS^{-1} \\ -D^{-1}CT^{-1} & S^{-1} \end{bmatrix}$.

   (d) $\begin{bmatrix} T^{-1} & (C - DB^{-1}A)^{-1} \\ (B - AC^{-1}D)^{-1} & S^{-1} \end{bmatrix}$.

   (e) $\begin{bmatrix} I & -A^{-1}B \\ 0 & I \end{bmatrix} \begin{bmatrix} A^{-1} & 0 \\ 0 & S^{-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ -CA^{-1} & I \end{bmatrix}$.

   (f) $\begin{bmatrix} A^{-1} & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} A^{-1}B \\ -I \end{bmatrix} S^{-1}[CA^{-1}, -I]$.

   (g) $\begin{bmatrix} (M/D)^{-1} & (M/C)^{-1} \\ (M/B)^{-1} & (M/A)^{-1} \end{bmatrix}$.

10. If the indicated inverses exist, then

$$\begin{aligned} (A - BD^{-1}C)^{-1} &= A^{-1} + A^{-1}B(D - CA^{-1}B)^{-1}CA^{-1} \\ &= -C^{-1}D(B - AC^{-1}D)^{-1} \\ &= -(C - DB^{-1}A)^{-1}DB^{-1} \\ &= C^{-1}D(D - CA^{-1}B)^{-1}CA^{-1} \\ &= A^{-1}B(D - CA^{-1}B)^{-1}DB^{-1}. \end{aligned}$$

11. Let A and $A(\beta, \alpha)$ be nonsingular. Then

$$A^{-1}[\alpha, \beta] = (A/A(\beta, \alpha))^{-1}.$$

    In particular,

$$A^{-1}(\alpha) = (A/\alpha)^{-1}.$$

12. Let $M = \begin{bmatrix} A & B & E \\ C & D & F \\ G & H & L \end{bmatrix}$. If A is square and nonsingular, then

$$M/A = \begin{bmatrix} D & F \\ H & L \end{bmatrix} - \begin{bmatrix} C \\ G \end{bmatrix} A^{-1}[B, E] = \begin{bmatrix} D & F \\ H & L \end{bmatrix} - \begin{bmatrix} CA^{-1}B & CA^{-1}E \\ GA^{-1}B & GA^{-1}E \end{bmatrix}.$$

If D is square and nonsingular, then

$$M/D = \begin{bmatrix} A & E \\ G & L \end{bmatrix} - \begin{bmatrix} B \\ H \end{bmatrix} D^{-1}[C, F] = \begin{bmatrix} A & E \\ G & L \end{bmatrix} - \begin{bmatrix} BD^{-1}C & BD^{-1}F \\ HD^{-1}C & HD^{-1}F \end{bmatrix}.$$

Examples:

1. Let $A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$. Then $A/[a_{11}] = A/[1] = [4 - 3 \cdot 2] = [-2]$.
2. Let $A = \begin{bmatrix} 1 & 2 & e \\ 3 & 4 & \pi \end{bmatrix}$. Then

$$A/[1] = [4, \pi] - 3[2, e] = [-2, \pi - 3e]; \quad A/[4] = [1, e] - [2][4]^{-1}[3, \pi] = [-\tfrac{1}{2}, e - \tfrac{\pi}{2}]$$

and

$$A/[e] = [3, 4] - [\pi][e]^{-1}[1, 2] = [3 - e^{-1}\pi, 4 - 2e^{-1}\pi].$$

3. Let $A = \begin{bmatrix} a & x \\ x^* & B \end{bmatrix}$, where a is a scalar, x is a row vector, and B is a square matrix. If $a \neq 0$, then $A/[a] = B - \frac{1}{a}x^*x$ and $\det A = a \det(B - \frac{1}{a}x^*x)$. If B is nonsingular, then $A/B = a - xB^{-1}x^*$ and $\det A = (a - xB^{-1}x^*) \det B$.
4. Let $A = \begin{bmatrix} I & E \\ F & G \end{bmatrix}$, in which I is an identity matrix. Then $A/I = G - FE$.
5. Let

$$M = \begin{bmatrix} 2 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & \frac{6}{5} \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix},$$

in which

$$A = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} = B^T, \quad D = \begin{bmatrix} 1 & 1 \\ 1 & \frac{6}{5} \end{bmatrix}.$$

Then

$$M/A = D - CA^{-1}B = \begin{bmatrix} 1 & 1 \\ 1 & \frac{6}{5} \end{bmatrix} - \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{3}{10} \end{bmatrix}.$$

12.3 Closure Properties

Facts:

The following facts can be found in Chapter 4 of [Zha05].

1. Let $A = [a_{ij}] \in \mathbb{C}^{n \times n}$, let α be a proper subset of $\{1, \ldots, n\}$, and let $A[\alpha]$ be nonsingular. The following properties X of A are inherited by a Schur complement A/α, i.e., if A is X then A/α is X.
   - (a) diagonal
   - (b) tridiagonal
   - (c) lower triangular
   - (d) upper triangular
   - (e) symmetric

(f) positive semidefinite

(g) Hermitian

(h) lower Hessenberg (i.e., $a_{ij} = 0$ whenever $j - i > 1$)

(i) upper Hessenberg (i.e., $a_{ij} = 0$ whenever $i - j > 1$)

(j) all principal submatrices are nonsingular

(k) all principal minors are positive

(l) positive definite Hermitian part
Note: the Hermitian part of a square matrix A is $H(A) = \frac{1}{2}(A + A^*)$.

(m) row (or column) diagonally dominant
Note: $A = (a_{ij}) \in \mathbb{C}^{n \times n}$ is row diagonally dominant if, for each i, $1 \leq i \leq n$,

$$|a_{ii}| \geq \sum_{j \neq i} |a_{ij}| \tag{12.3}$$

and A is strictly row diagonally dominant if all of the inequalities in (12.3) are strict.

(n) row (or column) strictly diagonally dominant

(o) H-matrix
Note: A square matrix A is an H-matrix if there is a nonsingular diagonal matrix D such that AD (or DA) is strictly row (or column) diagonally dominant.

(p) M-matrix
Note: M-matrix is a nonsingular matrix all of whose off-diagonal entries are nonpositive (i.e., Z-matrix) and whose inverse is nonnegative.

(q) Cassini matrix
Note: A is a Cassini matrix if for each pair i, j,

$$|a_{ii}||a_{jj}| > \sum_{s=1}^{n} |a_{is}| \sum_{s=1}^{n} |a_{js}|.$$

Examples:

The following matrix classes are not closed under Schur complements.

1. If A is a *Z-matrix* (i.e., all off-diagonal entries of A are nonpositive), A/α need not be. Let

$$A = \begin{bmatrix} -1 & -2 & -3 \\ -2 & 0 & -1 \\ -5 & -6 & 4 \end{bmatrix}.$$

Then A is a Z–matrix, but $A/[a_{11}] = \begin{bmatrix} 4 & 5 \\ 4 & 19 \end{bmatrix}$ is not a Z–matrix.

2. If A is nonnegative (i.e., all entries of A are nonnegative), A/α need not be. Let

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 2 \\ 1 & 1 & 1 \end{bmatrix}.$$

For $\alpha = \{1, 2\}$, $A/\alpha = [-1]$ is not nonnegative.

3. If A is completely positive (CP) (i.e., $A = BB^T$ for some nonnegative matrix B), A/α need not be. Let
$$A = \begin{bmatrix} 9 & 7 & 7 \\ 7 & 6 & 5 \\ 7 & 5 & 6 \end{bmatrix} = \begin{bmatrix} 2 & 1 & 2 \\ 2 & 1 & 1 \\ 1 & 1 & 2 \end{bmatrix} \begin{bmatrix} 2 & 1 & 2 \\ 2 & 1 & 1 \\ 1 & 1 & 2 \end{bmatrix}^T.$$
Then A is a CP matrix. But $A/[a_{11}] = \frac{1}{9}\begin{bmatrix} 5 & -4 \\ -4 & 5 \end{bmatrix}$ is not CP.
4. If A is totally positive (TP) (i.e., all minors are positive), A/α need not be. Let
$$A = \begin{bmatrix} 1 & 2 & 3 \\ 1 & 4 & 9 \\ 1 & 8 & 27 \end{bmatrix}.$$
Then A is TP. But $A/[a_{22}] = \begin{bmatrix} \frac{1}{2} & -\frac{3}{2} \\ -1 & 9 \end{bmatrix}$ is not TP since it contains negative entries.
5. If A is stable (i.e., all eigenvalues of A lie in the open right complex half-plane), A/α need not be. Let
$$A = \begin{bmatrix} -1 & 4 \\ -2 & 3 \end{bmatrix}.$$
Then A is stable. But $A/[a_{11}] = [-5]$ is not.
6. If A is unitary (i.e., $A^*A = AA^* = I$), A/α need not be. Let
$$A = \frac{1}{\sqrt{2}}\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}.$$
Then A is unitary, but $A/[a_{11}] = [\sqrt{2}]$ is not unitary.
7. If A is normal (i.e., $A^*A = AA^*$), A/α need not be. Let
$$A = \begin{bmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \\ 2 & 3 & 1 \end{bmatrix}.$$
Then A is normal, but $A/[a_{11}] = \begin{bmatrix} -5 & -7 \\ -1 & -5 \end{bmatrix}$ is not.
8. If A is irreducible (i.e., for any permutation matrix P, P^TAP is not in the form $\begin{bmatrix} B & 0 \\ C & D \end{bmatrix}$, where B is square), A/α need not be. Let
$$A = \begin{bmatrix} 1 & 2 & 2 \\ 1 & 1 & 2 \\ 1 & 0 & 1 \end{bmatrix}.$$
Then A is irreducible, but $A/[a_{11}] = \begin{bmatrix} -1 & 0 \\ -2 & -1 \end{bmatrix}$ is reducible.
9. If A is a Hankel matrix (i.e., for some sequence $a_2, a_3, \ldots, a_{2n}$, $a_{ij} = a_{i+j}$ for all i, j), A/α need not be. Let
$$A = \begin{bmatrix} 1 & 2 & 0 & 1 \\ 2 & 0 & 1 & 3 \\ 0 & 1 & 3 & -1 \\ 1 & 3 & -1 & 1 \end{bmatrix}.$$
Then A is a Hankel matrix, but
$$A/[a_{11}] = \begin{bmatrix} -4 & 1 & 1 \\ 1 & 3 & -1 \\ 1 & -1 & 0 \end{bmatrix}$$
is not a Hankel matrix.

10. If A is a Toeplitz matrix (i.e., for some sequence $a_{-(n-1)}, \ldots, a_{-1}, a_0, a_1, \ldots, a_{n-1}$, $a_{ij} = a_{j-i}$ for all i, j), A/α need not be. Let
$$A = \begin{bmatrix} 1 & 0 & 2 & 1 \\ 3 & 1 & 0 & 2 \\ -1 & 3 & 1 & 0 \\ 1 & -1 & 3 & 1 \end{bmatrix}.$$
Then A is a Toeplitz matrix, but
$$A/[a_{11}] = \begin{bmatrix} 1 & -6 & -1 \\ 3 & 3 & 1 \\ -1 & 1 & 0 \end{bmatrix}$$
is not a Toeplitz matrix.
11. If A is circulant (i.e., the rows of A from top to bottom are, respectively, $c_1, c_2, \ldots, c_n$; $c_2, \ldots, c_n, c_1$; …; $c_n, \ldots, c_{n-1}$), A/α need not be. Let
$$A = \begin{bmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \\ 2 & 3 & 1 \end{bmatrix}.$$
Then A is circulant, but $A/[a_{11}] = \begin{bmatrix} -5 & -7 \\ -1 & -5 \end{bmatrix}$ is not.

12.4 The Quotient Formula and Schur Complements of Products

Facts:

The following facts can be found in Chapters 1 and 4 of [Zha05].

1. The *Crabtree–Haynsworth quotient formula*: Let M, A, and E be nonsingular matrices such that E is a principal submatrix of A and A is a principal submatrix of M:
$$M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}, \quad A = \begin{bmatrix} E & F \\ G & H \end{bmatrix}.$$
Then A/E is a nonsingular principal submatrix of M/E and
$$M/A = (M/E)\,/\,(A/E).$$
2. *Sequential property of Schur complements*: Let A be an n-square matrix all of whose principal submatrices are nonsingular. If α is a proper subset of $\{1, \ldots, n\}$ and β is a proper subset of α^c, then $(A/A[\alpha])[\beta] = A[\alpha \cup \beta]/A[\alpha]$ and
$$A/A[\alpha \cup \beta] = (A/A[\alpha])/(A/A[\alpha])[\beta].$$
The indices in β are interpreted in the obvious way in A/α.
3. Let
$$M = \begin{bmatrix} A & B & E \\ C & D & F \\ G & H & L \end{bmatrix}.$$

Denote

$$A' = \begin{bmatrix} A & B \\ C & D \end{bmatrix}, \quad B' = \begin{bmatrix} B & E \\ D & F \end{bmatrix}, \quad C' = \begin{bmatrix} C & D \\ G & H \end{bmatrix}, \quad D' = \begin{bmatrix} D & F \\ H & L \end{bmatrix}.$$

If D and D' are square and nonsingular (and hence D'/D is nonsingular), then

$$M/D = \begin{bmatrix} A'/D & B'/D \\ C'/D & D'/D \end{bmatrix}$$

and

$$M/D' = (M/D)/(D'/D) = (A'/D) - (B'/D)(D'/D)^{-1}(C'/D).$$

Moreover,

$$\det M \det D = \det A' \det D' - \det B' \det C'.$$

4. Let A be a square matrix all of whose principal submatrices are nonsingular, and let D and E be nonsingular diagonal matrices. Then

$$(DA)/(DA)[\alpha] = D[\alpha^c](A/A[\alpha]);$$

$$(AE)/(AE)[\alpha] = (A/A[\alpha])E[\alpha^c];$$

$$(DAE)/(DAE)[\alpha] = D[\alpha^c](A/A[\alpha])E[\alpha^c].$$

5. Let

$$M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}, L = \begin{bmatrix} X & 0 \\ Y & Z \end{bmatrix}, \text{ and } R = \begin{bmatrix} U & V \\ 0 & W \end{bmatrix}$$

be conformally partitioned square matrices of the same size. Suppose that A, X, and U are nonsingular. Then XAU is a principal submatrix of LMR and

$$(LMR) / (XAU) = (L/X)\,(M/A)\,(R/U) = Z\,(M/A)\,W.$$

6. Let L_1 and L_2 be block lower triangular matrices with respective nonsingular diagonal blocks $L_1^{(i)}$ and $L_2^{(i)}$, both of the same size n_i, $i = 1, \ldots, m$. Let $\alpha = \{1, \ldots, \sum_{i=1}^{k} n_i\}$, $k < m$ (i.e., α corresponds to the *leading* principal submatrix containing the first k blocks on the main diagonal). Then

$$(L_1L_2)/\alpha = (L_1/\alpha)(L_2/\alpha) = L_1\,(\alpha)\,L_2\,(\alpha)\,.$$

Likewise, for block upper triangular matrices R_1 and R_2 similarly partitioned,

$$(R_1R_2)/\alpha = (R_1/\alpha)(R_2/\alpha) = R_1\,(\alpha)\,R_2\,(\alpha)\,.$$

7. Let L_1 and L_2 be $n \times n$ nonsingular lower (or upper) triangular matrices and let $\alpha = \{1, \ldots, k\}$, $k < n$. Then

$$(L_1L_2)/\alpha = (L_1/\alpha)(L_2/\alpha) = L_1\,(\alpha)\,L_2\,(\alpha)\,.$$

8. Let L and R be block lower and upper triangular matrices with respective nonsingular diagonal blocks L_i and R_i, both of the same size n_i, $i = 1, \ldots, m$. Let $\alpha = \{1, \ldots, \sum_{i=1}^{k} n_i\}$, $k < m$ (i.e., α corresponds to the *leading* principal submatrix containing the first k blocks on the main diagonal). Then

$$(LR)/\alpha = (L/\alpha)(R/\alpha) = L\,(\alpha)\,R\,(\alpha)\,.$$

In particular, if L is a block lower triangular nonsingular matrix and α is the row (also column) index set for the first k blocks on the main diagonal of L, then

$$(LL^*)/\alpha = (L/\alpha)(L^*/\alpha) = L\,(\alpha)\,(L\,(\alpha))^*\,.$$

9. Let L and U be $n \times n$ lower and upper triangular matrices, respectively. Let D be an $n \times n$ diagonal matrix and let $M = LDU$. If M is nonsingular, then for any $\alpha = \{1, \ldots, k\}$, $k < n$,
$$M/\alpha = (L/\alpha)(D/\alpha)(U/\alpha) = L(\alpha)D(\alpha)U(\alpha).$$
Thus, M/α has a factorization of the same form.
10. *Cholesky factorization*: If N is positive definite, then there is a lower triangular matrix L such that $N = LL^*$. Moreover, $N/\alpha = L(\alpha)(L(\alpha))^*$ is a Cholesky factorization of the Schur complement N/α, $\alpha = \{1, \ldots, k\}$, $k < n$.
11. Let $T \in \mathbb{C}^{n \times n}$ and let $\alpha \subset \{1, \ldots, n\}$. If T and $T[\alpha]$ are nonsingular, then
$$(T^*T)/\alpha \preceq (T^*/\alpha)(T/\alpha).$$
12. Let $L \in \mathbb{C}^{n \times n}$ be nonsingular and let $\alpha \subset \{1, \ldots, n\}$. If L is lower triangular, then
$$(L^*L)/\alpha \preceq (L^*/\alpha)(L/\alpha).$$
If R is upper triangular, then
$$(R^*R)/\alpha = (R^*/\alpha)(R/\alpha).$$
13. Let N be any $n \times n$ positive definite matrix and let T be an $n \times n$ nonsingular matrix such that $T[\alpha]$ is nonsingular, where $\alpha \subset \{1, \ldots, n\}$. Then
$$(T^*NT)/\alpha \preceq (T^*/\alpha)N[\alpha^c](T/\alpha).$$
14. Let L and R be block lower and upper triangular matrices with nonsingular main diagonal blocks L_i and R_i, both of size n_i, respectively, $i = 1, \ldots, m$. Let $\alpha = \{1, \ldots, \sum_{i=1}^{k} n_i\}$, $k < m$ (i.e., α corresponds to the *leading* principal submatrix containing the first k blocks on the main diagonal). For $\beta = \alpha^c$ in $\{1, \ldots, \sum_{i=1}^{m} n_i\}$,
$$(RL)/\beta = (R/\beta)(L/\beta) = R(\beta)\,L(\beta).$$

Examples:

1. Let $L = \begin{bmatrix} 1 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 4 & 5 \end{bmatrix}$. Then
$$LL^* = \begin{bmatrix} 1 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 4 & 5 \end{bmatrix} \begin{bmatrix} 1 & 2 & 0 \\ 0 & 3 & 4 \\ 0 & 0 & 5 \end{bmatrix} = \begin{bmatrix} 1 & 2 & 0 \\ 2 & 13 & 12 \\ 0 & 12 & 41 \end{bmatrix}.$$
For $\alpha = \{1\}$, $\beta = \{2\}$, and $\gamma = \{1, 2\}$, we have
$$(LL^*)/\alpha = \begin{bmatrix} 13 & 12 \\ 12 & 41 \end{bmatrix} - \begin{bmatrix} 2 \\ 0 \end{bmatrix} [2, 0] = \begin{bmatrix} 9 & 12 \\ 12 & 41 \end{bmatrix} = \begin{bmatrix} 3 & 0 \\ 4 & 5 \end{bmatrix} \begin{bmatrix} 3 & 4 \\ 0 & 5 \end{bmatrix} = (L/\alpha)(L^*/\alpha).$$
$$\begin{aligned}(LL^*)/\beta &= \begin{bmatrix} 1 & 0 \\ 0 & 41 \end{bmatrix} - \frac{1}{13} \begin{bmatrix} 2 \\ 12 \end{bmatrix} [2, 12] = \frac{1}{13} \begin{bmatrix} 9 & -24 \\ -24 & 389 \end{bmatrix} \\ &\preceq \frac{1}{9} \begin{bmatrix} 9 & -24 \\ -24 & 289 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ -\frac{8}{3} & 5 \end{bmatrix} \begin{bmatrix} 1 & -\frac{8}{3} \\ 0 & 5 \end{bmatrix} = (L/\beta)(L^*/\beta).\end{aligned}$$

$$(LL^*)/\gamma = [41] - [0, 12] \begin{bmatrix} 1 & 2 \\ 2 & 13 \end{bmatrix}^{-1} \begin{bmatrix} 0 \\ 12 \end{bmatrix} = [25] = (L/\gamma)(L^*/\gamma).$$

2. Let $L = \begin{bmatrix} 1 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 4 & 5 \end{bmatrix}$. Then

$$L^*L = \begin{bmatrix} 1 & 2 & 0 \\ 0 & 3 & 4 \\ 0 & 0 & 5 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 4 & 5 \end{bmatrix} = \begin{bmatrix} 5 & 6 & 0 \\ 6 & 25 & 20 \\ 0 & 20 & 25 \end{bmatrix}.$$

For $\alpha = \{1\}$, $\beta = \{2\}$, and $\gamma = \{3\}$, we have

$$(L^*L)/\alpha = \begin{bmatrix} 25 & 20 \\ 20 & 25 \end{bmatrix} - \frac{1}{5} \begin{bmatrix} 6 \\ 0 \end{bmatrix} [6, 0] = \begin{bmatrix} \frac{89}{5} & 20 \\ 20 & 25 \end{bmatrix} \preceq \begin{bmatrix} 25 & 20 \\ 20 & 25 \end{bmatrix} = (L^*/\alpha)(L/\alpha).$$

$$\begin{aligned} (L^*L)/\beta &= \begin{bmatrix} 5 & 0 \\ 0 & 25 \end{bmatrix} - \frac{1}{25} \begin{bmatrix} 6 \\ 20 \end{bmatrix} [6, 20] = \begin{bmatrix} \frac{89}{25} & -\frac{24}{5} \\ -\frac{24}{5} & 9 \end{bmatrix} \\ &\preceq \begin{bmatrix} 1 & -\frac{8}{3} \\ 0 & 5 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ -\frac{8}{3} & 5 \end{bmatrix} = \begin{bmatrix} \frac{73}{9} & -\frac{40}{3} \\ -\frac{40}{3} & 25 \end{bmatrix} = (L^*/\beta)(L/\beta). \end{aligned}$$

$$(L^*L)/\gamma = \begin{bmatrix} 5 & 6 \\ 6 & 25 \end{bmatrix} - \frac{1}{25} \begin{bmatrix} 0 \\ 20 \end{bmatrix} [0, 20] = \begin{bmatrix} 5 & 6 \\ 6 & 9 \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 0 & 3 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 2 & 3 \end{bmatrix} = (L^*/\gamma)(L/\gamma).$$

Let $\delta = \{1, 2\}$ and $\eta = \{2, 3\}$. Then

$$(L^*L)/\delta = [25 - \tfrac{2000}{89}] \prec [25] = (L^*/\delta)(L/\delta); \quad (L^*L)/\eta = [1] = (L^*/\eta)(L/\eta).$$

12.5 Haynsworth's Inertia Addition Theorem

Definitions:

The **inertia** of an $n \times n$ Hermitian matrix A is the ordered triple

$$\text{in}(A) \equiv (\pi(A),\ \nu(A),\ \delta(A)),$$

in which $\pi(A)$, $\nu(A)$, and $\delta(A)$ are the numbers of the positive, negative, and zero eigenvalues of A, respectively (including multiplicities).

By $\text{in}(A) \geq (a, b, c)$ we mean that $\pi(A) \geq a$, $\nu(A) \geq b$, and $\delta(A) \geq c$.

Facts:

The following facts can be found in Chapter 1 of [Zha05].

1. Let A be a square matrix. Then $\text{rank}\,(A) = \pi(A) + \nu(A)$.
2. *Sylvester's Law of Inertia*: Let A and B be $n \times n$ Hermitian matrices. Then there is a nonsingular $n \times n$ matrix G such that $B = G^*AG$ if and only if $\text{in}\,(A) = \text{in}\,(B)$. The inertias of *congruent Hermitian matrices are the same.

3. *Haynsworth's Inertia Addition Theorem*: Let A be Hermitian and let A_{11} be a nonsingular principal submatrix of A. Then
$$\text{in}(A) = \text{in}(A_{11}) + \text{in}(A/A_{11}).$$
4. For any $n \times n$ Hermitian matrix A and any index sets α and $\beta \subseteq \{1, \ldots, n\}$,
$$\text{in}(A) \geq \text{in}(A\,[\alpha]), \text{ if } A[\alpha] \text{ is nonsingular,}$$
and
$$\text{in}(A) \geq (\max_{\alpha} \pi(A\,[\alpha]), \ \max_{\beta} \nu(A\,[\beta]), 0).$$
5. Let $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$ be a partitioned $n \times n$ Hermitian matrix in which A_{11} is $k \times k$ and positive definite, and A_{22} is negative semidefinite. If the last $n - k$ columns of A are linearly independent, then A is nonsingular and
$$\text{in}(A) = (k, \ n - k, \ 0)\,.$$
6. Let A be an $n \times n$ Hermitian matrix partitioned as
$$A = \begin{bmatrix} B & c \\ c^* & a \end{bmatrix},$$
in which c is a column vector of size $n - 1$ and a is a real scalar. Suppose that $\text{in}(B) = (p, \ q, \ z)$. Then
$$\text{in}(A) \geq (p, \ q, \ z - 1)\,.$$
If $\delta(A) = z - 1$, then
$$\text{in}(A) = (p + 1, \ q + 1, \ z - 1)\,.$$
7. Let $A \in \mathcal{H}_n$, let B be a $k \times k$ principal submatrix of A, and let $d = \delta(B) - \delta(A)$.
   (a) It is always true that
$$\pi(A) \geq \pi(B) \quad \text{and} \quad \nu(A) \geq \nu(B).$$
   (b) If $d > 0$, then
$$d \leq n - k, \ \pi(A) \geq \pi(B) + d \quad \text{and} \quad \nu(A) \geq \nu(B) + d.$$
   (c) If $d = n - k$, then
$$\text{in}(A) = (\pi(B) + n - k, \ \nu(B) + n - k, \ \delta(B) - n + k).$$
   (d) If A is nonsingular, then $\delta(B) = n - k$ and
$$\text{in}(A) = (\pi(B) + n - k, \ \nu(B) + n - k, \ 0).$$
8. Let $A \in \mathcal{H}_n$ and let B be a $k \times k$ principal submatrix of A. Then
$$\delta(B) - n + k \leq \delta(A) \leq \delta(B) + n - k.$$

9. Let A and B be square matrices of orders n and m, respectively, $n \geq m$. Let X be an $n \times m$ matrix such that $AX = XB$, and partition X and A as

$$X = \begin{bmatrix} X_1 \\ X_2 \end{bmatrix}, \; X_1 \in \mathbb{C}^{m\times m} \quad \text{and} \quad A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \; A_{11} \in \mathbb{C}^{m\times m}.$$

Assume that X_1 is nonsingular. Let

$$C = \begin{bmatrix} X_1 & A_{12} \\ X_2 & A_{22} \end{bmatrix}$$

and let $\sigma(Y)$ denote the spectrum (set of all eigenvalues) of a square matrix Y. Then

$$\sigma(A) = \sigma(B) \cup \sigma(C/X_1).$$

10. *Inertia of skew block upper triangular matrices*: Let A be $m \times m$ and Hermitian, let B be $m \times n$ and have rank r, and let

$$M = \begin{bmatrix} A & B \\ B^* & 0 \end{bmatrix}.$$

Then $\text{in}(M) \geq (r,\ r,\ 0)$. If B is nonsingular, then $\text{in}(M) = (m,\ m,\ 0)$.

Examples:

1. Let $A = \begin{bmatrix} 2 & -1 \\ -1 & 3 \end{bmatrix}$. A has two positive eigenvalues $\frac{5\pm\sqrt{5}}{2}$, so $\text{in}(A) = (2, 0, 0)$.
2. Let $B = \begin{bmatrix} 0 & i \\ -i & 1 \end{bmatrix}$. The eigenvalues of B are $\frac{1\pm\sqrt{5}}{2}$, so $\text{in}(B) = (1, 1, 0)$.
3. Let $C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, $\alpha = \{1\}$. Then $\text{in}(C) = (1, 1, 0) \not\geq \text{in}(C[\alpha]) = (0, 0, 1)$.
4. Let $D = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$, $\alpha = \{1\}$. Then $\delta(D) = 1 > \delta(D[\alpha]) = 0$.
5. Let $E = \begin{bmatrix} 1 & 1 \\ 1 & 2 \end{bmatrix}$, $\alpha = \{1\}$. Then $\delta(E) = 0 = \delta(E[\alpha])$.
6. Let $H = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \\ 3 & 6 & -5 \end{bmatrix}$. H is singular and has rank 2, so $\delta(H) = 1$. H has both positive and negative main diagonal entries, so neither H nor $-H$ is positive semidefinite. Thus, $\text{in}(H) = (1, 1, 1)$. (In fact, the eigenvalues of H are $8.336, 0, -8.336$.) Since $B = \begin{bmatrix} 4 & 6 \\ 6 & -5 \end{bmatrix}$ is a nonsingular principal submatrix of H, $\text{in}(B) \leq \text{in}(H) = (1, 1, 1)$, and hence $\text{in}(B) = (1, 1, 0)$.
7. The eigenvalues of $H = \begin{bmatrix} 3 & -2 & 4 \\ -2 & 6 & 2 \\ 4 & 2 & 3 \end{bmatrix}$ are 7, 7, -2, so $\text{in}(H) = (2, 1, 0)$.
8. Let $D = \text{diag}(1, 0, -1)$. Then for any nonsingular $P \in \mathbb{C}^{3\times 3}$, $\text{in}(P^*DP) = (1, 1, 1)$. No 2×2 principal submatrix of P^*DP is positive definite or negative definite.
9. Let

$$M = \begin{bmatrix} 2 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & x \end{bmatrix} = \begin{bmatrix} A & B \\ C & X \end{bmatrix},$$

in which

$$A = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} = B^T, \quad X = \begin{bmatrix} 1 & 1 \\ 1 & x \end{bmatrix}.$$

Then

$$M/A = X - CA^{-1}B = \begin{bmatrix} 1 & 1 \\ 1 & x \end{bmatrix} - \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ 1 & 2x-3 \end{bmatrix}.$$

$\text{in}(A) = (2,0,0)$ and $\text{in}(M/A) = (2,0,0)$ if $x > 2$; (1, 0, 1) if $x = 2$; (1, 1, 0) if $x < 2$. Since $\text{in}(M) = \text{in}(A) + \text{in}(M/A)$, $M \succ 0$ for any $x > 2$, $M \succeq 0$ for any $x \geq 2$, and $M \not\succeq 0$ if $x < 2$.

10. Let

$$M = \begin{bmatrix} 2 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & x \end{bmatrix} = \begin{bmatrix} A & C \\ B & X \end{bmatrix},$$

in which

$$A = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} = B^T, \quad X = \begin{bmatrix} 1 & 1 \\ 1 & x \end{bmatrix}.$$

Then

$$M/A = X - BA^{-1}C = \begin{bmatrix} 1 & 1 \\ 1 & x \end{bmatrix} - \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} & 0 \\ 0 & x-1 \end{bmatrix}.$$

Since $\text{in}(M) \geq \text{in}(M/A)$ and M/A has a nonnegative eigenvalue, M is not positive semidefinite for any scalar x.

12.6 The Generalized Schur Complement

Definitions:

In the definition (12.1) of the Schur complement, we assumed that the submatrix $A[\alpha, \beta]$ is square and nonsingular. We now allow $A[\alpha, \beta]$ to be any submatrix. The *Moore–Penrose generalized inverse* $A^\dagger$ of A is the unique matrix X such that

$$AXA = A, \quad XAX = X, \quad (AX)^* = AX, \quad (XA)^* = XA.$$

Let A be an $m \times n$ matrix, and let α and β be subsets of $\{1, \ldots, m\}$ and $\{1, \ldots, n\}$, respectively. The **generalized Schur complement** of $A[\alpha, \beta]$ in A is

$$A/A[\alpha, \beta] = A\left[\alpha^c, \beta^c\right] - A\left[\alpha^c, \beta\right] (A[\alpha, \beta])^\dagger A\left[\alpha, \beta^c\right].$$

Denote by $CS(X)$ and $RS(X)$ the column and row spaces of the matrix X, respectively.

Facts:

The following facts can be found in Chapters 1 and 6 of [Zha05].

1. Let M be a matrix partitioned as

$$M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}.$$

If $CS(B) \subseteq CS(A)$ and $RS(C) \subseteq RS(A)$, then

$$\begin{bmatrix} I & 0 \\ -CA^\dagger & I \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} I & -A^\dagger B \\ 0 & I \end{bmatrix} = \begin{bmatrix} A & 0 \\ 0 & M/A \end{bmatrix}$$

and hence

$$\operatorname{rank} M = \operatorname{rank} A + \operatorname{rank}(M/A).$$

If no inclusion condition is imposed on the row and column spaces, it is possible that $\operatorname{rank} M > \operatorname{rank} A + \operatorname{rank}(M/A)$; see Example 2.

2. Suppose that M is positive semidefinite and partitioned as

$$M = \begin{bmatrix} A & B \\ B^* & C \end{bmatrix},$$

in which A and C are square. Then:

   (a) There is a matrix R such that $B = AR$,

   (b) $CS(B) \subseteq CS(A)$, and

   (c) $B = AA^\dagger B$.

   (d) There is a matrix L such that $B = LC$,

   (e) $RS(B) \subseteq RS(C)$, and

   (f) $B = BC^\dagger C$.

3. Suppose that M is Hermitian and partitioned as

$$M = \begin{bmatrix} A & B \\ B^* & C \end{bmatrix},$$

in which A and C are square. Then

$$M \succeq 0 \text{ if and only if } A \succeq 0,\ CS(B) \subseteq CS(A), \text{ and } M/A \succeq 0.$$

4. Suppose that M is positive semidefinite and partitioned as

$$M = \begin{bmatrix} A & B \\ B^* & C \end{bmatrix},$$

in which A and C are square. Let

$$X = \begin{bmatrix} A^\dagger + A^\dagger B\,(M/A)^\dagger\, B^* A^\dagger & -A^\dagger B\,(M/A)^\dagger \\ -\,(M/A)^\dagger\, B^* A^\dagger & (M/A)^\dagger \end{bmatrix}.$$

Then $X = M^\dagger$ if and only if $\operatorname{rank} M = \operatorname{rank} A + \operatorname{rank} C$.

Examples:

1. Let $A = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$. Then $A = U^* \begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix} U$, with $U = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}$, and

$$A^\dagger = U^* \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & 0 \end{bmatrix} U = \frac{1}{4} \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}.$$

2. Let

$$M = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & 0 \\ 1 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} A & B \\ B^* & 0 \end{bmatrix},$$

in which

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix}.$$

Then $M/A = 0 - B^* A^\dagger B = \frac{1}{4}\begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}$; $\operatorname{rank}(M) = 4 > 2 = 1 + 1 = \operatorname{rank}(A) + \operatorname{rank}(M/A)$.

12.7 Interlacing Eigenvalues

Facts:

The following facts can be found in Chapter 2 of [Zha05].

1. Let $H \in \mathcal{H}_n$ and let $\alpha \subseteq \{1, \ldots, n\}$ be an index set with k elements, $1 \le k < n$. If the principal submatrix $H[\alpha]$ is positive definite, then

$$\lambda_i(H) \ge \lambda_i(H/\alpha \oplus 0) \ge \lambda_{i+k}(H), \quad i = 1, \ldots, n-k.$$

If $H[\alpha]$ is negative definite, then

$$\lambda_i(H) \ge \lambda_{i+k}(H/\alpha \oplus 0) \ge \lambda_{i+k}(H), \quad i = 1, \ldots, n-k.$$

2. Let H (or $-H$) be an $n \times n$ positive semidefinite matrix, let $\alpha \subseteq \{1, \ldots, n\}$, and let $H[\alpha]$ be a $k \times k$ nonsingular principal submatrix of H, $1 \le k < n$. Then

$$\lambda_i(H) \ge \lambda_i(H/\alpha) \ge \lambda_{i+k}(H), \quad i = 1, \ldots, n-k.$$

3. Let H be an $n \times n$ positive semidefinite matrix, let $\alpha \subseteq \{1, 2, \ldots, n\}$, and let $H[\alpha]$ be a $k \times k$ nonsingular principal submatrix of H, $1 \le k < n$. Then

$$\lambda_i(H) \ge \lambda_i(H[\alpha^c]) \ge \lambda_i(H/\alpha) \ge \lambda_{i+k}(H), \quad i = 1, \ldots, n-k.$$

4. Let H be an $n \times n$ nonsingular Hermitian matrix, let $\alpha \subseteq \{1, \ldots, n\}$, and let $H[\alpha]$ be a $k \times k$ nonsingular principal submatrix of H, $1 \le k < n$. Then

$$\lambda_i(H^{-1}) \ge \lambda_i[(H/\alpha)^{-1}] \ge \lambda_{i+k}(H^{-1}), \quad i = 1, \ldots, n-k.$$

5. Let H be an $n \times n$ Hermitian matrix, let $\alpha \subseteq \{1, \ldots, n\}$, and let $H[\alpha]$ be a $k \times k$ nonsingular principal submatrix of H, $1 \le k < n$. Then

$$\lambda_i(H^\dagger) \ge \lambda_i[(H/\alpha)^\dagger] \ge \lambda_{i+k}(H^\dagger), \quad i = 1, \ldots, n-k,$$

in which $X^\dagger$ is the Moore–Penrose generalized inverse of X.

6. Extremal characterization with respect to the Loewner partial order: Let H be an $n \times n$ positive semidefinite matrix partitioned as

$$H = \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix},$$

in which H_{11} is a $k \times k$ leading principal submatrix of H, $1 \le k < n$. Then

$$H/H_{11} = \max\left\{X : \ H - (0_k \oplus X) \succeq 0, \ X = X^*, \ X \in \mathbb{C}^{(n-k)\times(n-k)}\right\}$$

and

$$H/H_{11} = \min\left\{[Y, I_{n-k}]H[Y, I_{n-k}]^* : \ Y \in \mathbb{C}^{(n-k)\times k}\right\}.$$

Furthermore, the maximum is achieved at $X = H/H_{11}$ and the minimum is achieved at $Y = -H_{21}H_{11}^{\dagger}$. (Note: Here "max" and "min" are in the Loewner ordering sense.)

7. Let H be an $n \times n$ Hermitian matrix and let $Z = -H[\alpha^c, \alpha]H[\alpha]^{\dagger}$. If $\alpha = \{1, \dots, k\}$, $k < n$, then

$$H/\alpha = [Z, I]H[Z, I]^*$$

and if $\alpha = \{k+1, \dots, n\}$, $k < n$, then

$$H/\alpha = [I, Z]H[I, Z]^*.$$

8. Let $A \in \mathbb{C}^{m\times n}$, $l = \min\{m, n\}$, $\alpha \subset \{1, \dots, l\}$ and $\sigma_1(A) \ge \cdots \ge \sigma_l(A)$ denote the ordered singular values of A. Then

$$\sigma_i(A/\alpha) \ge \lambda_i^{1/2}\left((AA^*)/\alpha\right) \ge \sigma_{i+|\alpha|}(A), \quad i = 1, \dots, l - |\alpha|$$

and

$$\sigma_i(A/\alpha) \ge \lambda_i^{1/2}\left((A^*A)/\alpha\right) \ge \sigma_{i+|\alpha|}(A), \quad i = 1, \dots, l - |\alpha|.$$

Examples:

1. Let $B = \begin{bmatrix} 0 & i \\ -i & 1 \end{bmatrix}$. Since $B/[b_{22}] = [-1]$, B must have a negative eigenvalue. In fact, the eigenvalues of B are $\frac{1\pm\sqrt{5}}{2}$, i.e., approximately 1.618 and -0.618. Observe that the eigenvalue of $B/[b_{22}]$ does not interlace them.
2. Let $H = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \\ 3 & 6 & -5 \end{bmatrix}$, $\alpha = \{1\}$. $H/\alpha = \begin{bmatrix} 4 & 6 \\ 6 & -5 \end{bmatrix} - \begin{bmatrix} 2 \\ 3 \end{bmatrix}[2, 3] = \begin{bmatrix} 0 & 0 \\ 0 & -14 \end{bmatrix}$, and the eigenvalues of $(H/\alpha)^{\dagger}$ are 0 and $-\frac{1}{14}$ which interlace the eigenvalues of $H^{\dagger}$:

$$\lambda_1(H^{\dagger}) \ge 0 \ge \lambda_2(H^{\dagger}) \ge -\frac{1}{14} \ge \lambda_3(H^{\dagger}).$$

In fact, the eigenvalues of $H^{\dagger}$ are $0.1195, 0, -0.1195$.

3. Let

$$H = \begin{bmatrix} 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 2 \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix},$$

in which

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} = B^T, \quad D = \begin{bmatrix} 1 & 1 \\ 1 & 2 \end{bmatrix}.$$

Then H/D can be obtained by computing $[I, Z]H[I, Z]^*$, where $Z = -BD^{-1} = \begin{bmatrix} -2 & 1 \\ -2 & 1 \end{bmatrix}$.

In fact, $H/D = \begin{bmatrix} -1 & -1 \\ -1 & -1 \end{bmatrix}$.

12.8 Positive Semidefinite Matrices

Facts:

The following facts can be found in Chapter 1 of [Zha05].

1. Let $A \in \mathbb{C}^{n\times n}$ be Hermitian, let $\alpha \subset \{1,\ldots,n\}$, and let $A[\alpha]$ be nonsingular. Then:
   (a) $A \succ 0$ if and only if both $A[\alpha] \succ 0$ and $A/A[\alpha] \succ 0$.
   (b) $A \succeq 0$ if and only if $A[\alpha] \succ 0$ and $A/A[\alpha] \succeq 0$.
   (c) if $A \succeq 0$ and $A[\alpha] \succ 0$, then $A(\alpha) \succeq A/A[\alpha]$. Consequently,

   $$\det A(\alpha)\det(A/A[\alpha]) = (\det A)\,/\,(\det A[\alpha]) \geq 0.$$

   If $\alpha = \{1,\ldots,k\}$, $k < n$, and A is partitioned as

   $$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{12}^* & A_{22} \end{bmatrix}, \quad A_{11} = A[\alpha] \text{ is nonsingular,} \tag{12.4}$$

   then:
   (a′) $A \succ 0$ if and only if both $A_{11} \succ 0$ and $A/A_{11} \succ 0$.
   (b′) $A \succeq 0$ if and only if $A_{11} \succ 0$ and $A/A_{11} \succeq 0$.
   (c′) If $A \succeq 0$ and $A_{11} \succ 0$, then $A_{22} \succeq A/A_{11}$. Consequently,

   $$\det A_{22} \geq \det(A/A_{11}) = (\det A)\,/\,(\det A_{11}) \geq 0.$$

2. *Fischer's Inequality*: Let $A \in \mathbb{C}^{n\times n}$ be positive semidefinite, let $\alpha \subset \{1,\ldots,n\}$, and let $A[\alpha]$ be nonsingular. Then

   $$\det\left(A/A[\alpha]\right)\det\left(A/A[\alpha^c]\right) \leq \det A \leq (\det A[\alpha])\,(\det A[\alpha^c])\,.$$

   In particular, if A is partitioned as in (12.4), then

   $$\det(A/A_{11})\det(A/A_{22}) \leq \det A \leq (\det A_{11})\,(\det A_{22})\,.$$

3. Let A be an $n \times n$ positive semidefinite matrix, written as $A = T^*T$ for some $n \times n$ matrix T. If $\alpha \subset \{1,\ldots,n\}$ and $A[\alpha]$ is nonsingular, then

   $$A/\alpha = (T^*T)/\alpha \preceq (T^*/\alpha)(T/\alpha).$$

4. Let A and B be $n \times n$ positive semidefinite matrices and let $\alpha \subset \{1,\ldots,n\}$. Then

   $$(A+B)/\alpha \succeq A/\alpha + B/\alpha.$$

Examples:

1. Let

   $$M = \begin{bmatrix} 2 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & x \end{bmatrix} = \begin{bmatrix} A & B \\ C & X \end{bmatrix},$$

   in which

   $$A = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} = B^T, \quad X = \begin{bmatrix} 1 & 1 \\ 1 & x \end{bmatrix}.$$

Then

$$M/A = X - CA^{-1}B = \begin{bmatrix} 1 & 1 \\ 1 & x \end{bmatrix} - \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ 1 & 2x-3 \end{bmatrix}.$$

In order that $M \succ 0$, we must require $x > 2$.

2. Let A and B be $n \times n$ positive definite matrices, and $X, Y \in \mathbb{C}^{n\times m}$. Then

$$M = \begin{bmatrix} A & X \\ X^* & X^*A^{-1}X \end{bmatrix} \succeq 0, \quad N = \begin{bmatrix} B & Y \\ Y^* & Y^*B^{-1}Y \end{bmatrix} \succeq 0.$$

Thus $M + N \succeq 0$. Taking the Schur complement of $A + B$ in $M + N$ gives

$$X^*A^{-1}X + Y^*B^{-1}Y \succeq (X+Y)^* \, (A+B)^{-1} \, (X+Y).$$

Likewise, for the Hadamard (Schur) product (i.e., entrywise product), we have

$$(X^*A^{-1}X) \circ (Y^*B^{-1}Y) \succeq (X \circ Y)^* \, (A \circ B)^{-1} \, (X \circ Y).$$

3. Let A and B be $m \times n$ complex matrices. Then

$$\begin{bmatrix} I & A^* \\ B & I \end{bmatrix} \begin{bmatrix} I & B^* \\ A & I \end{bmatrix} = \begin{bmatrix} I + A^*A & A^* + B^* \\ A + B & I + BB^* \end{bmatrix} \succeq 0.$$

Taking the Schur complement of $I + A^*A$, we arrive at

$$I + BB^* \succeq (A+B)(I + A^*A)^{-1}(A+B)^*,$$

which ensures, when A and B are square, that

$$\det(I + A^*A)\det(I + BB^*) \geq |\det(A+B)|^2.$$

Quadratic, Bilinear, and Sesquilinear Forms

Raphael Loewy
Technion

13.1 Bilinear Forms 13-1
13.2 Symmetric Bilinear Forms 13-3
13.3 Alternating Bilinear Forms 13-5
13.4 φ-Sesquilinear Forms 13-6
13.5 Hermitian Forms 13-8
References 13-10

Bilinear forms are maps defined on $V \times V$, where V is a vector space, and are linear with respect to each of their variables. There are some similarities between bilinear forms and inner products that are discussed in Chapter 5. Basic properties of bilinear forms, symmetric bilinear forms, and alternating bilinear forms are discussed. The latter two types of forms satisfy additional symmetry conditions.

Quadratic forms are obtained from symmetric bilinear forms by equating the two variables. They are widely used in many areas. A canonical representation of a quadratic form is given when the underlying field is $\mathbb{R}$ or $\mathbb{C}$.

When the field is the complex numbers, it is standard to expect the form to be conjugate linear rather than linear in the second variable; such a form is called sesquilinear. The role of a symmetric bilinear form is played by a Hermitian sesquilinear form. The idea of a sesquilinear form can be generalized to an arbitrary automorphism, encompassing both bilinear and sesquilinear forms as φ-sesquilinear forms, where φ is an automorphism of the field.

Quadratic, bilinear, and φ-sesquilinear forms have applications to classical matrix groups. (See Chapter 84 for more information.)

13.1 Bilinear Forms

It is assumed throughout this section that V is a finite dimensional vector space over a field F.

Definitions:

A ***bilinear form*** on V is a map f from $V \times V$ into F which satisfies

$$f(a\mathbf{u_1} + b\mathbf{u_2}, \mathbf{v}) = af(\mathbf{u_1}, \mathbf{v}) + bf(\mathbf{u_2}, \mathbf{v}), \quad \mathbf{u_1}, \mathbf{u_2}, \mathbf{v} \in V, \ \ a, b \in F,$$

and

$$f(\mathbf{u}, a\mathbf{v_1} + b\mathbf{v_2}) = af(\mathbf{u}, \mathbf{v_1}) + bf(\mathbf{u}, \mathbf{v_2}), \quad \mathbf{u}, \mathbf{v_1}, \mathbf{v_2} \in V, \ \ a, b \in F\,.$$

The space of all bilinear forms on V is denoted $B(V, V, F)$.

Let $\mathcal{B} = (\mathbf{w_1}, \mathbf{w_2}, \dots, \mathbf{w_n})$ be an ordered basis of V and let $f \in B(V, V, F)$. ***The matrix representing*** f ***relative to*** $\mathcal{B}$ is the matrix $A = [a_{ij}] \in F^{n\times n}$ such that $a_{ij} = f(\mathbf{w_i}, \mathbf{w_j})$.

The ***rank*** of $f \in B(V, V, F)$, $\operatorname{rank}(f)$, is $\operatorname{rank}(A)$, where A is a matrix representing f relative to an arbitrary ordered basis of V.

$f \in B(V, V, F)$ is ***nondegenerate*** if its rank is equal to $\dim V$, and ***degenerate*** if it is not nondegenerate.

Let $A, B \in F^{n\times n}$. B is ***congruent*** to A if there exists an invertible $P \in F^{n\times n}$ such that $B = P^T AP$.

Let $f, g \in B(V, V, F)$. g is ***equivalent*** to f if there exists an ordered basis $\mathcal{B}$ of V such that the matrix of g relative to $\mathcal{B}$ is congruent to the matrix of f relative to $\mathcal{B}$.

Let T be a linear operator on V and let $f \in B(V, V, F)$. T ***preserves*** f if $f(T\mathbf{u}, T\mathbf{v}) = f(\mathbf{u}, \mathbf{v})$ for all $\mathbf{u}, \mathbf{v} \in V$.

Facts:

Let $f \in B(V, V, F)$. The following facts can be found in [HK71, Chap. 10].

1. f is a linear functional in each of its variables when the other variable is held fixed.
2. Let $\mathcal{B} = (\mathbf{w_1}, \mathbf{w_2}, \dots, \mathbf{w_n})$ be an ordered basis of V and let

$$\mathbf{u} = \sum_{i=1}^{n} a_i \mathbf{w_i}, \qquad \mathbf{v} = \sum_{i=1}^{n} b_i \mathbf{w_i}.$$

   Then,

$$f(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^{n}\sum_{j=1}^{n} a_i b_j f(\mathbf{w_i}, \mathbf{w_j}).$$

3. Let A denote the matrix representing f relative to $\mathcal{B}$, and let $[\mathbf{u}]_{\mathcal{B}}$ and $[\mathbf{v}]_{\mathcal{B}}$ be the vectors in F^n that are the coordinate vectors of $\mathbf{u}$ and $\mathbf{v}$, respectively, with respect to $\mathcal{B}$. Then $f(\mathbf{u}, \mathbf{v}) = [\mathbf{u}]_{\mathcal{B}}^T A[\mathbf{v}]_{\mathcal{B}}$.
4. Let $\mathcal{B}$ and $\mathcal{B}'$ be ordered bases of V, and P be the matrix whose columns are the $\mathcal{B}$-coordinates of vectors in $\mathcal{B}'$. Let $f \in B(V, V, F)$. Let A and B denote the matrices representing f relative to $\mathcal{B}$ and $\mathcal{B}'$. Then

$$B = P^T AP.$$

5. The concept of rank of f, as given, is well defined.
6. The set $L = \{\mathbf{v} \in V : f(\mathbf{u}, \mathbf{v}) = 0 \text{ for all } \mathbf{u} \in V\}$ is a subspace of V and $\operatorname{rank}(f) = \dim V - \dim L$. In particular, f is nondegenerate if and only if $L = \{0\}$.
7. Suppose that $\dim V = n$. The space $B(V, V, F)$ is a vector space over F under the obvious addition of two bilinear forms and multiplication of a bilinear form by a scalar. Moreover, $B(V, V, F)$ is isomorphic to $F^{n\times n}$.
8. Congruence is an equivalence relation on $F^{n\times n}$.
9. Let $f \in B(V, V, F)$ be nondegenerate. Then the set of all linear operators on V, which preserve f, is a group under the operation of composition.

Examples:

1. Let $A \in F^{n\times n}$. The map $f : F^n \times F^n \to F$ defined by

$$f(\mathbf{u}, \mathbf{v}) = \mathbf{u}^T A\mathbf{v} = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij} u_i v_j, \quad \mathbf{u}, \mathbf{v} \in F^n,$$

is a bilinear form. Since $f(\mathbf{e_i}, \mathbf{e_j}) = a_{ij}, \quad i, j = 1, 2, \ldots, n,$ f is represented in the standard basis of F^n by A. It follows that $\text{rank}(f) = \text{rank}(A)$, and f is nondegenerate if and only if A is invertible.

2. Let $C \in F^{m\times m}$ and $\text{rank}(C) = k$. The map $f : F^{m\times n} \times F^{m\times n} \to F$ defined by $f(A, B) = \text{tr}(A^T CB)$ is a bilinear form. This follows immediately from the basic properties of the trace function. To compute $\text{rank}(f)$, let L be defined as in Fact 6, that is, $L = \{B \in F^{m\times n} : \text{tr}(A^T CB) = 0 \text{ for all } A \in F^{m\times n}\}$. It follows that $L = \{B \in F^{m\times n} : CB = 0\}$, which implies that $\dim L = n(m - k)$. Hence, $\text{rank}(f) = mn - n(m - k) = kn$. In particular, f is nondegenerate if and only if C is invertible.
3. Let $\mathbb{R}[x; n]$ denote the space of all real polynomials of the form $\sum_{i=0}^{n} a_i x^i$. Then $f(p(x), q(x)) = p(0)q(0) + p(1)q(1) + p(2)q(2)$ is a bilinear form on $\mathbb{R}[x; n]$. It is nondegenerate if $n = 2$ and degenerate if $n \geqslant 3$.

13.2 Symmetric Bilinear Forms

It is assumed throughout this section that V is a finite dimensional vector space over a field F.

Definitions:

Let $f \in B(V, V, F)$. Then f is ***symmetric*** if $f(\mathbf{u}, \mathbf{v}) = f(\mathbf{v}, \mathbf{u})$ for all $\mathbf{u}, \mathbf{v} \in V$.

Let f be a symmetric bilinear form on V, and let $\mathbf{u}, \mathbf{v} \in V$; $\mathbf{u}$ and $\mathbf{v}$ are ***orthogonal with respect to*** f if $f(\mathbf{u}, \mathbf{v}) = 0$.

Let f be a symmetric bilinear form on V. The ***quadratic form corresponding to*** f is the map $g : V \to F$ defined by $g(\mathbf{v}) = f(\mathbf{v}, \mathbf{v})$, $\mathbf{v} \in V$.

A symmetric bilinear form f on a real vector space V is ***positive semidefinite*** (***positive definite***) if $f(\mathbf{v}, \mathbf{v}) \geqslant 0$ for all $\mathbf{v} \in V$ $(f(\mathbf{v}, \mathbf{v}) > 0$ for all $0 \neq \mathbf{v} \in V)$.

f is ***negative semidefinite*** (***negative definite***) if $-f$ is positive semidefinite (positive definite).

The ***signature*** of a real symmetric matrix A is the integer $\pi - \nu$, where (π, ν, δ) is the inertia of A. (See Section 9.3.)

The ***signature*** of a real symmetric bilinear form is the signature of a matrix representing the form relative to some basis.

Facts:

Additional facts about real symmetric matrices can be found in Chapter 9. Except where another reference is provided, the following facts can be found in [Coh89, Chap. 8], [HJ13, Chap. 4], or [HK71, Chap. 10].

1. A positive definite bilinear form is nondegenerate.
2. An inner product on a real vector space is a positive definite symmetric bilinear form. Conversely, a positive definite symmetric bilinear form on a real vector space is an inner product.
3. Let $\mathcal{B}$ be an ordered basis of V and let $f \in B(V, V, F)$. Let A be the matrix representing f relative to $\mathcal{B}$. Then f is symmetric if and only if A is a symmetric matrix, that is, $A = A^T$.
4. Let f be a symmetric bilinear form on V and let g be the quadratic form corresponding to f. Suppose that the characteristic of F is not 2. Then f can be recovered from g:
$$f(\mathbf{u}, \mathbf{v}) = \tfrac{1}{2}[g(\mathbf{u} + \mathbf{v}) - g(\mathbf{u}) - g(\mathbf{v})] \quad \text{for all } \mathbf{u}, \mathbf{v} \in V.$$
5. Let f be a symmetric bilinear form on V and suppose that the characteristic of F is not 2. Then there exists an ordered basis $\mathcal{B}$ of V such that the matrix representing f

relative to it is diagonal; i.e., if $A \in F^{n\times n}$ is a symmetric matrix, then A is congruent to a diagonal matrix.

6. Suppose that V is a complex vector space and f is a symmetric bilinear form on V. Let $r = \text{rank}(f)$. Then there is an ordered basis $\mathcal{B}$ of V such that the matrix representing f relative to $\mathcal{B}$ is $I_r \oplus \mathbf{0}$. In matrix language, this fact states that if $A \in \mathbb{C}^{n\times n}$ is symmetric with $\text{rank}(A) = r$, then it is congruent to $I_r \oplus \mathbf{0}$.
7. The only invariant of $n \times n$ complex symmetric matrices under congruence is the rank.
8. Two complex $n \times n$ symmetric matrices are congruent if and only if they have the same rank.
9. (*Sylvester's law of inertia for symmetric bilinear forms*) Suppose that V is a real vector space and f is a symmetric bilinear form on V. Then there is an ordered basis $\mathcal{B}$ of V such that the matrix representing f relative to it has the form $I_\pi \oplus -I_\nu \oplus \mathbf{0}_\delta$. Moreover, π, ν, and δ do not depend on the choice of $\mathcal{B}$, but only on f.
10. (*Sylvester's law of inertia for matrices*) If $A \in \mathbb{R}^{n\times n}$ is symmetric, then A is congruent to the diagonal matrix $D = I_\pi \oplus -I_\nu \oplus \mathbf{0}_\delta$, where $(\pi, \nu, \delta) = \text{in}(A)$.
11. There are exactly two invariants of $n \times n$ real symmetric matrices under congruence, namely the rank and the signature.
12. Two real $n \times n$ symmetric matrices are congruent if and only if they have the same rank and the same signature.
13. The signature of a real symmetric bilinear form is well defined.
14. Two real symmetric bilinear forms are equivalent if and only if they have the same rank and the same signature.
15. [Hes68] Let $n \geqslant 3$ and let $A, B \in \mathbb{R}^{n\times n}$ be symmetric. Suppose that $\mathbf{x} \in \mathbb{R}^n$, $\mathbf{x}^T A\mathbf{x} = \mathbf{x}^T B\mathbf{x} = 0 \Rightarrow \mathbf{x} = 0$. Then $\exists\, \mathbf{a}, \mathbf{b} \in \mathbb{R}$ such that $\mathbf{a}A + \mathbf{b}B$ is positive definite.
16. The group of linear operators preserving the form $f(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^n u_i v_i$ on $\mathbb{R}^n$ is the real n-dimensional orthogonal group, while the group preserving the same form on $\mathbb{C}^n$ is the complex n-dimensional orthogonal group.

Examples:

1. Consider Example 13.1.1. The map f is a symmetric bilinear form if and only if $A = A^T$. The quadratic form g corresponding to f is given by

$$g(\mathbf{u}) = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}u_i u_j, \quad \mathbf{u} \in F^n.$$

2. Consider Example 13.1.2. The map f is a symmetric bilinear form if and only if $C = C^T$.
3. The symmetric bilinear form $f_\mathbf{a}$ on $\mathbb{R}^2$ given by

$$f_a(\mathbf{u}, \mathbf{v}) = u_1v_1 - 2u_1v_2 - 2u_2v_1 + au_2v_2, \quad \mathbf{u}, \mathbf{v} \in \mathbb{R}^2, \quad a \in \mathbb{R} \text{ is a parameter},$$

is an inner product on $\mathbb{R}^2$ if and only if $a > 4$.

4. Since we consider in this chapter only finite dimensional vector spaces, let V be any finite dimensional subspace of $C[0, 1]$, the space of all real valued, continuous functions on $[0, 1]$. Then the map $f : V \times V \to \mathbb{R}$ defined by

$$f(\mathbf{u}, \mathbf{v}) = \int_0^1 t^3 u(t)v(t)dt, \quad \mathbf{u}, \mathbf{v} \in V,$$

is a symmetric bilinear form on V.

Applications:

1. Conic sections: Consider the set of points (x_1, x_2) in $\mathbb{R}^2$, which satisfy the equation

$$ax_1^2 + bx_1x_2 + cx_2^2 + dx_1 + ex_2 + f = 0,$$

   where $a, b, c, d, e, f \in \mathbb{R}$. The solution set is a conic section, namely an ellipse, hyperbola, parabola, or a degenerate form of those. The analysis of this equation depends heavily on the quadratic form $ax_1^2 + bx_1x_2 + cx_2^2$, which is represented in the standard basis of $\mathbb{R}^2$ by $A = \begin{bmatrix} a & b/2 \\ b/2 & c \end{bmatrix}$. If the solution of the quadratic equation above represents a nondegenerate conic section, then its type is determined by the sign of $4ac - b^2$. More precisely, the conic is an ellipse, hyperbola, or parabola if $4ac - b^2$ is positive, negative, or zero, respectively.
2. Theory of small oscillations: Suppose a mechanical system undergoes small oscillations about an equilibrium position. Let $x_1, x_2, \ldots, x_n$ denote the coordinates of the system, and let $\mathbf{x} = (x_1, x_2, \ldots, x_n)^T$. Then the kinetic energy of the system is given by a quadratic form (in the velocities $\dot{x}_1, \dot{x}_2, \ldots, \dot{x}_n$) $\frac{1}{2}\dot{\mathbf{x}}^T A\dot{\mathbf{x}}$, where A is a positive definite matrix. If $\mathbf{x} = 0$ is the equilibrium position, then the potential energy of the system is given by another quadratic form $\frac{1}{2}\mathbf{x}^T B\mathbf{x}$, where $B = B^T$. The equations of motion are $A\ddot{\mathbf{x}} + B\mathbf{x} = 0$. It is known that A and B can be simultaneously diagonalized, that is, there exists an invertible $P \in \mathbb{R}^{n\times n}$ such that P^TAP and P^TBP are diagonal matrices. This can be used to obtain the solution of the system.

13.3 Alternating Bilinear Forms

It is assumed throughout this section that V is a finite dimensional vector space over a field F.

Definitions:

Let $f \in B(V, V, F)$. Then f is ***alternating*** if $f(\mathbf{v}, \mathbf{v}) = 0$ for all $\mathbf{v} \in V$. f is ***antisymmetric*** if $f(\mathbf{u}, \mathbf{v}) = -f(\mathbf{v}, \mathbf{u})$ for all $\mathbf{u}, \mathbf{v} \in V$.

Let $A \in F^{n\times n}$. Then A is ***alternating*** if $a_{ii} = 0$, $i = 1, 2, \ldots, n$ and $a_{ji} = -a_{ij}$, $1 \leqslant i < j \leqslant n$.

Facts:

The following facts can be found in [Coh89, Chap. 8], [HK71, Chap. 10], or [Lan99, Chap. 15].

1. Let $f \in B(V, V, F)$ be alternating. Then f is antisymmetric because for all $\mathbf{u}, \mathbf{v} \in V$,

$$f(\mathbf{u}, \mathbf{v}) + f(\mathbf{v}, \mathbf{u}) = f(\mathbf{u} + \mathbf{v}, \mathbf{u} + \mathbf{v}) - f(\mathbf{u}, \mathbf{u}) - f(\mathbf{v}, \mathbf{v}) = 0.$$

   The converse is true if the characteristic of F is not 2.
2. Let $A \in F^{n\times n}$ be an alternating matrix. Then $A^T = -A$. The converse is true if the characteristic of F is not 2.
3. Let $\mathcal{B}$ be an ordered basis of V and let $f \in B(V, V, F)$. Let A be the matrix representing f relative to $\mathcal{B}$. Then f is alternating if and only if A is an alternating matrix.
4. Let f be an alternating bilinear form on V and let $r = \operatorname{rank}(f)$. Then r is even and there exists an ordered basis $\mathcal{B}$ of V such that the matrix representing f relative to

it has the form
$$\underbrace{\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \oplus \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \oplus \cdots \oplus \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}}_{r/2-\text{times}} \oplus \mathbf{0}.$$

There is an ordered basis $\mathcal{B}_1$ where f is represented by the matrix $\begin{bmatrix} \mathbf{0} & I_{r/2} \\ -I_{r/2} & \mathbf{0} \end{bmatrix} \oplus \mathbf{0}$.

5. Let $f \in B(V, V, F)$ and suppose that the characteristic of F is not 2. Define:
$f_1 : V \times V \to F$ by $f_1(\mathbf{u}, \mathbf{v}) = \frac{1}{2}\left[f(\mathbf{u}, \mathbf{v}) + f(\mathbf{v}, \mathbf{u})\right]$, $\mathbf{u}, \mathbf{v} \in V$,
$f_2 : V \times V \to F$ by $f_2(\mathbf{u}, \mathbf{v}) = \frac{1}{2}\left[f(\mathbf{u}, \mathbf{v}) - f(\mathbf{v}, \mathbf{u})\right]$, $\mathbf{u}, \mathbf{v} \in V$.
Then f_1 (f_2) is a symmetric (alternating) bilinear form on V, and $f = f_1 + f_2$. Moreover, this representation of f as a sum of a symmetric and an alternating bilinear form is unique.
6. Let $A \in F^{n\times n}$ be an alternating matrix and suppose that A is invertible. Then n is even and A is congruent to the matrix $\begin{bmatrix} \mathbf{0} & I_{n/2} \\ -I_{n/2} & \mathbf{0} \end{bmatrix}$, so $\det(A)$ is a square in F. There exists a polynomial in $n(n-1)/2$ variables, called the *pfaffian*, such that $\det(A) = a^2$, where $a \in F$ is obtained by substituting into the Pfaffian the entries of A above the main diagonal for the indeterminates (see Section 4.3).
7. Let f be an alternating nondegenerate bilinear form on V. Then $\dim V = 2m$ for some positive integer m. The group of all linear operators on V that preserve f is the symplectic group.

Examples:

1. Consider Example 13.1.1. The map f is alternating if and only if the matrix A is an alternating matrix.
2. Consider Example 13.1.2. The map f is alternating if and only if C is an alternating matrix.
3. Let $C \in F^{n\times n}$. Define $f : F^{n\times n} \to F^{n\times n}$ by $f(A, B) = \operatorname{tr}(ACB - BCA)$. Then f is alternating.

13.4 φ-Sesquilinear Forms

This section generalizes Section 13.1, and is consequently very similar. This generalization is required by applications to matrix groups (see Chapter 84), but for most purposes such generality is not required, and the simpler discussion of bilinear forms in Section 13.1 is preferred. It is assumed throughout this section that V is a finite dimensional vector space over a field F and φ is an automorphism of F.

Definitions:

A **φ-sesquilinear form** on V is a map $f : V \times V \to F$, which is linear as a function in the first variable and φ-semilinear in the second, i.e.,

$$f(a\mathbf{u_1} + b\mathbf{u_2}, \mathbf{v}) = af(\mathbf{u_1}, \mathbf{v}) + bf(\mathbf{u_2}, \mathbf{v}), \quad \mathbf{u_1}, \mathbf{u_2}, \mathbf{v} \in V, \ \ a, b \in F,$$

and

$$f(\mathbf{u}, a\mathbf{v_1} + b\mathbf{v_2}) = \varphi(a)f(\mathbf{u}, \mathbf{v_1}) + \varphi(b)f(\mathbf{u}, \mathbf{v_2}), \quad \mathbf{u}, \mathbf{v_1}, \mathbf{v_2} \in V, \ \ a, b \in F.$$

In the case $F = \mathbb{C}$ and φ is complex conjugation, a φ-sesquilinear form is called a **sesquilinear form**. The space of all φ-sesquilinear forms on V is denoted $B(V, V, F, \varphi)$.

Let $\mathcal{B} = (\mathbf{w_1}, \mathbf{w_2}, \ldots, \mathbf{w_n})$ be an ordered basis of V and let $f \in B(V, V, F, \varphi)$. The ***matrix representing f relative to $\mathcal{B}$*** is the matrix $A = [a_{ij}] \in F^{n\times n}$ such that $a_{ij} = f(\mathbf{w_i}, \mathbf{w_j})$.

The ***rank*** of $f \in B(V, V, F, \varphi)$, rank$(f)$, is rank$(A)$, where A is a matrix representing f relative to an arbitrary ordered basis of V.

$f \in B(V, V, F, \varphi)$ is ***nondegenerate*** if its rank is equal to $\dim V$, and ***degenerate*** if it is not nondegenerate.

Let $A = [a_{ij}] \in F^{n\times n}$. $\varphi(A)$ is the $n \times n$ matrix whose i, j-entry is $\varphi(a_{ij})$.

Let $A, B \in F^{n\times n}$. B is ***φ-congruent*** to A if there exists an invertible $P \in F^{n\times n}$ such that $B = P^T A\varphi(P)$.

Let $f, g \in B(V, V, F, \varphi)$. g is ***φ-equivalent*** to f if there exists an ordered basis $\mathcal{B}$ of V such that the matrix of g relative to $\mathcal{B}$ is φ-congruent to the matrix of f relative to $\mathcal{B}$.

Let T be a linear operator on V and let $f \in B(V, V, F, \varphi)$. T ***preserves*** f if $f(T\mathbf{u}, T\mathbf{v}) = f(\mathbf{u}, \mathbf{v})$ for all $\mathbf{u}, \mathbf{v} \in V$.

Facts:

Let $f \in B(V, V, F, \varphi)$. The following facts can be obtained by obvious generalizations of the proofs of the corresponding facts in Section 13.1; see that section for references.

1. A bilinear form is a φ-sesquilinear form with the automorphism being the identity map.
2. Let $\mathcal{B} = (\mathbf{w_1}, \mathbf{w_2}, \ldots, \mathbf{w_n})$ be an ordered basis of V and let
$$\mathbf{u} = \sum_{i=1}^{n} a_i \mathbf{w_i}, \quad \mathbf{v} = \sum_{i=1}^{n} b_i \mathbf{w_i}.$$
Then,
$$f(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^{n}\sum_{j=1}^{n} a_i \varphi(b_j) f(\mathbf{w_i}, \mathbf{w_j}).$$
3. Let A denote the matrix representing the φ-sesquilinear f relative to $\mathcal{B}$, and let $[\mathbf{u}]_{\mathcal{B}}$ and $[\mathbf{v}]_{\mathcal{B}}$ be the vectors in F^n, which are the coordinate vectors of $\mathbf{u}$ and $\mathbf{v}$, respectively, with respect to $\mathcal{B}$. Then $f(\mathbf{u}, \mathbf{v}) = [\mathbf{u}]_{\mathcal{B}}^T A\varphi([\mathbf{v}]_{\mathcal{B}})$.
4. Let $\mathcal{B}$ and $\mathcal{B}'$ be ordered bases of V, and P be the matrix whose columns are the $\mathcal{B}$-coordinates of vectors in $\mathcal{B}'$. Let $f \in B(V, V, F, \varphi)$. Let A and B denote the matrices representing f relative to $\mathcal{B}$ and $\mathcal{B}'$. Then
$$B = P^T A\varphi(P).$$
5. The concept of rank of f, as given, is well defined.
6. The set $L = \{\mathbf{v} \in V : f(\mathbf{u}, \mathbf{v}) = 0 \text{ for all } \mathbf{u} \in V\}$ is a subspace of V and rank$(f) = \dim V - \dim L$. In particular, f is nondegenerate if and only if $L = \{0\}$.
7. Suppose that $\dim V = n$. The space $B(V, V, F, \varphi)$ is a vector space over F under the obvious addition of two φ-sesquilinear forms and multiplication of a φ-sesquilinear form by a scalar. Moreover, $B(V, V, F, \varphi)$ is isomorphic to $F^{n\times n}$.
8. φ-Congruence is an equivalence relation on $F^{n\times n}$.
9. Let $f \in B(V, V, F, \varphi)$ be nondegenerate. Then the set of all linear operators on V which preserve f is a group under the operation of composition.

Examples:

1. Let $F = \mathbb{Q}(\sqrt{5}) = \{a + b\sqrt{5} : a, b \in \mathbb{Q}\}$ and $\varphi(a + b\sqrt{5}) = a - b\sqrt{5}$. Define the φ-sesquilinear form f on F^2 by $f(\mathbf{u}, \mathbf{v}) = \mathbf{u}^T\varphi(\mathbf{v})$. $f([1 + \sqrt{5}, 3]^T, [-2\sqrt{5}, -1 + \sqrt{5}]^T) = (1 + \sqrt{5})(2\sqrt{5}) + 3(-1 - \sqrt{5}) = 7 - \sqrt{5}$.

   The matrix of f with respect to the standard basis is the identity matrix, rank $f = 2$, and f is nondegenerate.

2. Let $A \in F^{n\times n}$. The map $f : F^n \times F^n \to F$ defined by

$$f(\mathbf{u},\mathbf{v}) = \mathbf{u}^T A\varphi(\mathbf{v}) = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}u_i\varphi(v_j), \quad \mathbf{u},\mathbf{v} \in F^n,$$

   is a φ-sesquilinear form. Since $f(\mathbf{e_i},\mathbf{e_j}) = a_{ij}, \quad i,j = 1,2,\ldots,n,$ f is represented in the standard basis of F^n by A. It follows that $\text{rank}(f) = \text{rank}(A)$, and f is nondegenerate if and only if A is invertible.

13.5 Hermitian Forms

This section closely resembles the results related to symmetric bilinear forms on real vector spaces. We assume here that V is a finite dimensional complex vector space.

Definitions:

A ***Hermitian form*** on V is a map $f : V \times V \to \mathbb{C}$, which satisfies

$$f(a\mathbf{u_1} + b\mathbf{u_2},\mathbf{v}) = af(\mathbf{u_1},\mathbf{v}) + bf(\mathbf{u_2},\mathbf{v}), \quad \mathbf{u},\mathbf{v} \in V, \quad a,b \in \mathbb{C},$$

and

$$f(\mathbf{v},\mathbf{u}) = \overline{f(\mathbf{u},\mathbf{v})}, \quad \mathbf{u},\mathbf{v} \in V.$$

A Hermitian form f on V is ***positive semidefinite*** (***positive definite***) if $f(\mathbf{v},\mathbf{v}) \geqslant 0$ for all $\mathbf{v} \in V$ ($f(\mathbf{v},\mathbf{v}) > 0$ for all $0 \neq \mathbf{v} \in V$).

f is ***negative semidefinite*** (***negative definite***) if $-f$ is positive semidefinite (positive definite).

The ***signature*** of a Hermitian matrix A is the integer $\pi - \nu$, where (π,ν,δ) is the inertia of A. (See Section 9.3.)

The ***signature*** of a Hermitian form is the signature of a matrix representing the form.

Let $A, B \in \mathbb{C}^{n\times n}$. B is ****congruent*** to A if there exists an invertible $S \in \mathbb{C}^{n\times n}$ such that $B = S^*AS$ (where S^* denotes the Hermitian adjoint of S).

Let f, g be Hermitian forms on a finite dimensional complex vector space V. g is ****equivalent*** to f if there exists an ordered basis $\mathcal{B}$ of V such that the matrix of g relative to $\mathcal{B}$ is *congruent to the matrix of f relative to $\mathcal{B}$.

Facts:

Except where another reference is provided, the following facts can be found in [Coh89, Chap. 8], [HJ13, Chap. 4], or [Lan99, Chap. 15]. Let f be a Hermitian form on V.

1. A Hermitian form is sesquilinear.
2. A positive definite Hermitian form is nondegenerate.
3. f is a linear functional in the first variable and conjugate linear in the second variable, that is,

$$f(\mathbf{u}, a\mathbf{v_1} + b\mathbf{v_2}) = \bar{a}f(\mathbf{u},\mathbf{v_1}) + \bar{b}f(\mathbf{u},\mathbf{v_2}).$$

4. $f(\mathbf{v},\mathbf{v}) \in \mathbb{R}$ for all $\mathbf{v} \in V$.
5. An inner product on a complex vector space is a positive definite Hermitian form. Conversely, a positive definite Hermitian form on a complex vector space is an inner product.
6. (*Polarization formula*)

$$4f(\mathbf{u},\mathbf{v}) = f(\mathbf{u}+\mathbf{v},\mathbf{u}+\mathbf{v}) - f(\mathbf{u}-\mathbf{v},\mathbf{u}-\mathbf{v}) + \\ + if(\mathbf{u}+i\mathbf{v},\mathbf{u}+i\mathbf{v}) - if(\mathbf{u}-i\mathbf{v},\mathbf{u}-i\mathbf{v}).$$

7. Let $\mathcal{B} = (\mathbf{w_1}, \mathbf{w_2}, \ldots, \mathbf{w_n})$ be an ordered basis of V and let

   $$\mathbf{u} = \sum_{i=1}^{n} a_i \mathbf{w_i}, \quad \mathbf{v} = \sum_{i=1}^{n} b_i \mathbf{w_i}.$$

   Then

   $$f(\mathbf{u},\mathbf{v}) = \sum_{i=1}^{n}\sum_{j=1}^{n} a_i \bar{b}_j f(\mathbf{w_i}, \mathbf{w_j}).$$

8. Let A denote the matrix representing f relative to the basis $\mathcal{B}$. Then

   $$f(\mathbf{u},\mathbf{v}) = [\mathbf{u}]_{\mathcal{B}}^T A [\bar{\mathbf{v}}]_{\mathcal{B}}.$$

9. The matrix representing a Hermitian form f relative to any basis of V is a Hermitian matrix.
10. Let A, B be matrices that represent f relative to bases $\mathcal{B}$ and $\mathcal{B}'$ of V, respectively. Then B is *congruent to A.
11. (*Sylvester's law of inertia for Hermitian forms*, cf. 13.2) There exists an ordered basis $\mathcal{B}$ of V such that the matrix representing f relative to it has the form

    $$I_\pi \oplus -I_\nu \oplus \mathbf{0}_\delta.$$

    Moreover, π, ν, and δ depend only on f and not on the choice of $\mathcal{B}$.
12. (*Sylvester's law of inertia for Hermitian matrices*, cf. 13.2) If $A \in \mathbb{C}^{n\times n}$ is a Hermitian matrix, then A is *congruent to the diagonal matrix $D = I_\pi \oplus -I_\nu \oplus \mathbf{0}_\delta$, where $(\pi,\nu,\delta) = \text{in}(A)$.
13. There are exactly two invariants of $n \times n$ Hermitian matrices under *congruence, namely the rank and the signature.
14. Two Hermitian $n \times n$ matrices are *congruent if and only if they have the same rank and the same signature.
15. The signature of a Hermitian form is well-defined.
16. Two Hermitian forms are *equivalent if and only if they have the same rank and the same signature.
17. [HJ91, Theorem 1.3.5] Let A, $B \in \mathbb{C}^{n\times n}$ be Hermitian matrices. Suppose that $\mathbf{x} \in \mathbb{C}^n$, $\mathbf{x}^*A\mathbf{x} = \mathbf{x}^*B\mathbf{x} = 0 \;\Rightarrow\; \mathbf{x} = 0$. Then $\exists\ \mathbf{a}, \mathbf{b} \in \mathbb{R}$ such that $\mathbf{a}A + \mathbf{b}B$ is positive definite. This fact can be obtained from [HJ91], where it is stated in a slightly different form, using the decomposition of every square, complex matrix as a sum of a Hermitian matrix and a skew-Hermitian matrix.
18. The group of linear operators preserving the Hermitian form $f(u,v) = \sum_{i=1}^{n} u_i \bar{v}_i$ on $\mathbb{C}^n$ is the n-dimensional unitary group.

Examples:

1. Let $A \in \mathbb{C}^{n\times n}$ be a Hermitian matrix. The map $f\colon \mathbb{C}^n \times \mathbb{C}^n \to \mathbb{C}$ defined by $f(\mathbf{u},\mathbf{v}) = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij} u_i \bar{v}_j$ is a Hermitian form on $\mathbb{C}^n$.
2. Let $\psi_1, \psi_2, \ldots, \psi_k$ be linear functionals on V, and let $a_1, a_2, \ldots, a_k \in \mathbb{R}$. Then the map $f\colon V \times V \to \mathbb{C}$ defined by $f(\mathbf{u},\mathbf{v}) = \sum_{i=1}^{k} a_i \psi_i(\mathbf{u})\overline{\psi_i(\mathbf{v})}$ is a Hermitian form on V.
3. Let $H \in \mathbb{C}^{n\times n}$ be a Hermitian matrix.
   The map $f\colon \mathbb{C}^{n\times n} \times \mathbb{C}^{n\times n} \to \mathbb{C}$ defined by $f(A,B) = \text{tr}(AHB^*)$ is a Hermitian form.

14.1 Multilinear Maps

Unless otherwise stated, within this section V, U, and W as well as these letters with subscripts, superscripts, or accents, are finite dimensional vector spaces over a field F of characteristic zero.

Definitions:

A map φ from $V_1 \times \cdots \times V_m$ into U is a **multilinear map (m-linear map)** if it is linear on each coordinate, i.e., for every $\mathbf{v}_i, \mathbf{v}'_i \in V_i,\ i = 1, \ldots, m$ and for every $a \in F$ the following conditions hold:

(a) $\varphi(\mathbf{v}_1, \ldots, \mathbf{v}_i + \mathbf{v}'_i, \ldots, \mathbf{v}_m) = \varphi(\mathbf{v}_1, \ldots, \mathbf{v}_i, \ldots, \mathbf{v}_m) + \varphi(\mathbf{v}_1, \ldots, \mathbf{v}'_i, \ldots, \mathbf{v}_m)$;
(b) $\varphi(\mathbf{v}_1, \ldots, a\mathbf{v}_i, \ldots, \mathbf{v}_m) = a\varphi(\mathbf{v}_1, \ldots, \mathbf{v}_i, \ldots, \mathbf{v}_m)$.

The 2-linear maps and 3-linear maps are also called **bilinear** and **trilinear** maps, respectively. The 1–linear maps are just the linear maps.

If $U = F$ then a multilinear map into U is called a **multilinear form**.

The set of multilinear maps from $V_1 \times \cdots \times V_m$ into U, together with the operations defined as follows, is denoted $L(V_1, \ldots, V_m; U)$. For m-linear maps φ, ψ, and $a \in F$,

$$(\psi + \varphi)(\mathbf{v}_1, \ldots, \mathbf{v}_m) = \psi(\mathbf{v}_1, \ldots, \mathbf{v}_m) + \varphi(\mathbf{v}_1, \ldots, \mathbf{v}_m),$$
$$(a\varphi)(\mathbf{v}_1, \ldots, \mathbf{v}_m) = a\varphi(\mathbf{v}_1, \ldots, \mathbf{v}_m).$$

Let $(\mathbf{b}_{i1}, \ldots, \mathbf{b}_{in_i})$ be an ordered basis of $V_i, i = 1, \ldots, m$. Then $\Gamma(n_1, \ldots, n_m)$, or simply Γ, if there is no risk of confusion, denotes the set of maps α from $\{1, \ldots, m\}$ into $\mathbb{N}$ satisfying $1 \leq \alpha(i) \leq n_i$, $i = 1, \ldots, m$ and each of these maps α is often identified with the corresponding m-tuple

$(\alpha(1).\ldots,\alpha(m))$. For each $\alpha \in \Gamma$, the m-tuple of basis vectors $(\mathbf{b}_{1,\alpha(1)},\ldots,\mathbf{b}_{m\alpha(m)})$ is denoted by $\mathbf{b}_\alpha$. Unless otherwise stated Γ is considered ordered by lexicographic order.

Let p, q be positive integers. If φ is a $(p+q)$-linear map from $W_1 \times \cdots \times W_p \times V_1 \times \cdots \times V_q$ into U, then for each choice of $\mathbf{w}_i$, in W_i, $\mathbf{v}_j$ in V_j, $i = 1,\ldots,p$, $j = 1,\ldots,q$, the map

$$(\mathbf{v}_1,\ldots,\mathbf{v}_q) \longmapsto \varphi(\mathbf{w}_1,\ldots,\mathbf{w}_p,\mathbf{v}_1,\ldots,\mathbf{v}_q),$$

from $V_1 \times \cdots \times V_q$ into U, is denoted $\varphi_{\mathbf{w}_1,\ldots,\mathbf{w}_p}$, i.e.

$$\varphi_{\mathbf{w}_1,\ldots,\mathbf{w}_p}(\mathbf{v}_1,\ldots,\mathbf{v}_q) = \varphi(\mathbf{w}_1,\ldots,\mathbf{w}_p,\mathbf{v}_1,\ldots,\mathbf{v}_q).$$

Let η be a linear map from U into U' and θ_i a linear map from V_i' into V_i, $i = 1,\ldots,m$. If $(\mathbf{v}_1,\ldots,\mathbf{v}_m) \mapsto \varphi(\mathbf{v}_1,\ldots,\mathbf{v}_m)$ is a multilinear map from $V_1 \times \cdots \times V_m$ into U, $L(\theta_1,\ldots,\theta_m;\eta)(\varphi)$ denotes the map from $V_1' \times \cdots \times V_m'$ into U', defined by

$$(\mathbf{v}_1',\ldots,\mathbf{v}_m') \mapsto \eta(\varphi(\theta_1(\mathbf{v}_1'),\ldots,\theta_m(\mathbf{v}_m'))).$$

Facts:

The following facts can be found in [Mar73, Chap. 1] and [Mer97, Chap. 5].

1. If φ is a multilinear map, then $\varphi(\mathbf{v}_1,\ldots,0,\ldots,\mathbf{v}_m) = 0$.
2. The set $L(V_1,\ldots,V_m;U)$ is a vector space over F.
3. If φ is a $(p+q)-$linear map from $W_1 \times \cdots \times W_p \times V_1 \times \cdots V_q$ into U, then for every integer i, $1 \le i \le p$, and $\mathbf{w}_i \in W_i$, $1 \le i \le p$, the map $\varphi_{\mathbf{w}_1,\ldots,\mathbf{w}_p}$ is a q-linear map.
4. Under the same assumptions as in Fact 3, the map $(\mathbf{w}_1,\ldots,\mathbf{w}_p) \mapsto \varphi_{\mathbf{w}_1,\ldots,\mathbf{w}_p}$ from $W_1 \times \cdots \times W_p$ into $L(V_1,\ldots,V_q;U)$, is p-linear. A linear isomorphism from
$$L(W_1,\ldots,W_p,V_1,\ldots,V_q;U) \quad \text{onto} \quad L(W_1,\ldots,W_p;L(V_1,\ldots,V_q;U))$$
arises through this construction.
5. Let η be a linear map from U into U' and θ_i a linear map from V_i' into V_i, $i = 1,\ldots,m$. The map $L(\theta_1,\ldots,\theta_m;\eta)$ from $L(V_1,\ldots,V_m;U)$ into $L(V_1',\ldots,V_m';U')$ is a linear map. When $m = 1$, and $U = U' = F$, then $L(\theta_1, I)$ is the dual or adjoint linear map θ_1^* from V_1^* into $V_1'^*$.
6. $|\Gamma(n_1,\ldots,n_m)| = \prod_{i=1}^m n_i$ where $|\ |$ denotes cardinality.
7. Let $(\mathbf{y}_\alpha)_{\alpha\in\Gamma}$ be a family of vectors of U. Then, there exists a unique m-linear map φ from $V_1 \times \cdots \times V_m$ into U satisfying $\varphi(\mathbf{b}_\alpha) = \mathbf{y}_\alpha$, for every $\alpha \in \Gamma$.
8. If $(\mathbf{u}_1,\ldots,\mathbf{u}_n)$ is a basis of U, then $(\varphi_{i,\alpha} : \alpha \in \Gamma, i = 1,\ldots,m)$ is a basis of $L(V_1,\ldots,V_m;U)$, where $\varphi_{i,\alpha}$ is characterized by the conditions $\varphi_{i,\alpha}(\mathbf{b}_\beta) = \delta_{\alpha,\beta}\mathbf{u}_i$. Moreover, if φ is an m-linear map from $V_1 \times \cdots \times V_m$ into U such that for each $\alpha \in \Gamma$,
$$\varphi(\mathbf{b}_\alpha) = \sum_{i=1}^n a_{i,\alpha}\mathbf{u}_i,$$
then
$$\varphi = \sum_{\alpha,i} a_{i,\alpha}\varphi_{i,\alpha}.$$

Examples:

1. The map from F^m into F, $(a_1,\ldots,a_m) \to \prod_{i=1}^m a_i$, is an m-linear map.
2. Let V be a vector space over F. The map $(a,\mathbf{v}) \mapsto a\mathbf{v}$ from $F \times V$ into V is a bilinear map.
3. The map from $F^m \times F^m$ into F, $((a_1,\ldots,a_m),(b_1,\ldots,b_m)) \longmapsto \sum a_i b_i$, is bilinear.
4. Let U, V, and W be vector spaces over F. The map $(\theta,\eta) \mapsto \theta\eta$ from $L(V;W) \times L(U;V)$ into $L(U;W)$, given by composition, is bilinear.

5. The multiplication of matrices, $(A, B) \mapsto AB$, from $F^{m\times n} \times F^{n\times p}$ into $F^{m\times p}$, is bilinear. Observe that this example is the matrix counterpart of the previous one.
6. Let V and W be vector spaces over F. The evaluation map, from $L(V, W) \times V$ into W,

$$(\theta, \mathbf{v}) \longmapsto \theta(\mathbf{v}),$$

   is bilinear.
7. The map

$$((a_{11}, a_{21}, \ldots, a_{m1}), \ldots, (a_{1m}, a_{2m}, \ldots, a_{mm})) \to \det([a_{ij}])$$

   from the Cartesian product of m copies of F^m into F is m-linear.

14.2 Tensor Products

Definitions:

Let $V_1, \ldots, V_m, P$ be vector spaces over F. Let $\nu : V_1 \times \cdots \times V_m \longmapsto P$ be a multilinear map. The pair (ν, P) is called a **tensor product** of $V_1, \ldots, V_m$, or P is said to be **a tensor product of** $V_1, \ldots, V_m$ **with tensor multiplication** ν, if the following condition is satisfied:

> **Universal factorization property**
>
> If φ is a multilinear map from $V_1 \times \cdots \times V_m$ into the vector space U, then there exists a unique linear map, h, from P into U, that makes the following diagram commutative:
>
> $$\begin{tikzcd} V_1 \times \cdots \times V_m \arrow[r, "\nu"] \arrow[dr, "\varphi"'] & P \arrow[d, "h"] \\ & U \end{tikzcd}$$
>
> i.e., $h\nu = \varphi$.

If P is a tensor product of $V_1, \ldots, V_m$, with tensor multiplication ν, then P is denoted by $V_1 \otimes \cdots \otimes V_m$ and $\nu(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ is denoted by $\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m$ and is called the **tensor product of the vectors $\mathbf{v}_1, \ldots, \mathbf{v}_m$**.

The elements of $V_1 \otimes \cdots \otimes V_m$ are called **tensors**. The tensors that are the tensor product of m vectors are called **decomposable tensors**.

When $V_1 = \cdots = V_m = V$, the vector space $V_1 \otimes \cdots \otimes V_m$ is called the mth **tensor power** of V and is denoted by $\bigotimes^m V$. It is convenient to define $\bigotimes^0 V = F$ and assume that 1 is the unique decomposable tensor of $\bigotimes^0 V$. When we consider simultaneously different models of tensor product, sometimes we use alternative forms to denote the tensor multiplication like $\otimes'$, $\widetilde{\otimes}$, or $\widehat{\otimes}$ to emphasize these different choices.

Within this subsection, $V_1, \ldots, V_m$ are finite dimensional vector spaces over F and $(\mathbf{b}_{i1}, \ldots, \mathbf{b}_{in_i})$ denotes a basis of V_i, $i = 1, \ldots, m$. When V is a vector space and $\mathbf{x}_1, \ldots, \mathbf{x}_k \in V$, $\mathrm{Span}(\{\mathbf{x}_1, \ldots, \mathbf{x}_k\})$ denotes the subspace of V spanned by these vectors.

Facts:

The following facts can be found in [Mar73, Chap. 1] and [Mer97, Chap. 5].

1. If $V_1 \otimes \cdots \otimes V_m$ and $V_1 \otimes' \cdots \otimes' V_m$ are two tensor products of $V_1, \ldots, V_m$, then the unique linear map h from $V_1 \otimes \cdots \otimes V_m$ into $V_1 \otimes' \cdots \otimes' V_m$ satisfying

$$h(\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m) = \mathbf{v}_1 \otimes' \cdots \otimes' \mathbf{v}_m$$

is an isomorphism.

2. If $(\nu(\mathbf{b}_\alpha))_{\alpha\in\Gamma(n_1,\ldots,n_m)}$ is a basis of P, then the pair (ν, P) is a tensor product of $V_1, \ldots, V_m$. This is often the most effective way to check if a certain vector space is a model for the tensor product of given vector spaces. It also implies the existence of a tensor product.
3. If P is the tensor product of $V_1, \ldots, V_m$ with tensor multiplication ν, and $h : P \longmapsto Q$ is a linear isomorphism, then $(h\nu, Q)$ is a tensor product of $V_1, \ldots, V_m$.
4. When $m = 1$, it makes sense to speak of a tensor product of one vector space V and V itself is used as a model for that tensor product with the identity as tensor multiplication, i.e., $\bigotimes^1 V = V$.
5. (*Bilinear version of the universal property*) Given a multilinear map from $W_1 \times \cdots \times W_p \times V_1 \times \cdots \times V_q$ into U,

$$(\mathbf{w}_1, \ldots, \mathbf{w}_p, \mathbf{v}_1, \ldots, \mathbf{v}_q) \mapsto \varphi(\mathbf{w}_1, \ldots, \mathbf{w}_p, \mathbf{v}_1, \ldots, \mathbf{v}_q),$$

there exists a unique bilinear map χ from $(W_1 \otimes \cdots \otimes W_p) \times (V_1 \otimes \cdots \otimes V_q)$ into U satisfying

$$\chi(\mathbf{w}_1 \otimes \cdots \otimes \mathbf{w}_p, \mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_q) = \varphi(\mathbf{w}_1, \ldots, \mathbf{w}_p, \mathbf{v}_1, \ldots, \mathbf{v}_q),$$
$$\mathbf{w}_i \in W_i\ \mathbf{v}_j \in V_j,\ i = 1, \ldots, p,\ j = 1, \ldots, q.$$

6. Let $a \in F$ and $\mathbf{v}_i, \mathbf{v}_i' \in V_i,\ i = 1, \ldots, m$. As the consequence of the multilinearity of $\otimes$, the following equalities hold:
   (a) $\mathbf{v}_1 \otimes \cdots \otimes (\mathbf{v}_i + \mathbf{v}_i') \otimes \cdots \otimes \mathbf{v}_m$
   $= \mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_i \otimes \cdots \otimes \mathbf{v}_m + \mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_i' \otimes \cdots \otimes \mathbf{v}_m$,
   (b) $(a\mathbf{v}_1) \otimes \cdots \otimes \mathbf{v}_m = \cdots = \mathbf{v}_1 \otimes \cdots \otimes (a\mathbf{v}_m) = a(\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m)$,
   (c) $\mathbf{v}_1 \otimes \cdots \otimes 0 \otimes \cdots \otimes \mathbf{v}_m = 0$.
7. If one of the vector spaces V_i is zero, then $V_1 \otimes \cdots \otimes V_m = \{0\}$.
8. Write $\mathbf{b}_\alpha^\otimes$ to mean

$$\mathbf{b}_\alpha^\otimes := \mathbf{b}_{1\alpha(1)} \otimes \cdots \otimes \mathbf{b}_{m\alpha(m)}.$$

Then

$$(\mathbf{b}_\alpha^\otimes)_{\alpha\in\Gamma}$$

is a basis of $V_1 \otimes \cdots \otimes V_m$. This basis is said to be induced by the bases $(\mathbf{b_{i1}}, \ldots, \mathbf{b}_{in_i})$, $i = 1, \ldots, m$.

9. The decomposable tensors span the tensor product $V_1 \otimes \cdots \otimes V_m$. Furthermore, if the set C_i spans $V_i,\ i = 1, \ldots, m$, then the set $\{\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m\ :\ \mathbf{v}_i \in C_i,\ i = 1, \ldots, m\}$ spans $V_1 \otimes \cdots \otimes V_m$.
10. $\dim(V_1 \otimes \cdots \otimes V_m) = \prod_{i=1}^m \dim(V_i)$.
11. The tensor product is commutative,

$$V_1 \otimes V_2 = V_2 \otimes V_1,$$

meaning that if $V_1 \otimes V_2$ is a tensor product of V_1 and V_2, then $V_1 \otimes V_2$ is also a tensor product of V_2 and V_1 with tensor multiplication $(\mathbf{v}_2, \mathbf{v}_1) \mapsto \mathbf{v}_1 \otimes \mathbf{v}_2$.

In general, with a similar meaning, for any $\sigma \in S_m$,

$$V_1 \otimes \cdots \otimes V_m = V_{\sigma(1)} \otimes \cdots \otimes V_{\sigma(m)}.$$

12. The tensor product is associative,

$$(V_1 \otimes V_2) \otimes V_3 = V_1 \otimes (V_2 \otimes V_3) = V_1 \otimes V_2 \otimes V_3,$$

meaning that:

(a) A tensor product $V_1 \otimes V_2 \otimes V_3$ is also a tensor product of $V_1 \otimes V_2$ and V_3 (respectively of V_1 and $V_2 \otimes V_3$) with tensor multiplication defined (uniquely by Fact 5) for $\mathbf{v}_i \in V_i$, $i = 1, 2, 3$, by $(\mathbf{v}_1 \otimes \mathbf{v}_2) \otimes \mathbf{v}_3 = \mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3$ (respectively by $\mathbf{v}_1 \otimes (\mathbf{v}_2 \otimes \mathbf{v}_3) = \mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3$).

(b) And, $V_1 \otimes V_2) \otimes V_3$ (respectively $V_1 \otimes (V_2 \otimes V_3)$ is a tensor product of V_1, V_2, V_3 with tensor multiplication defined by $\mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3 = (\mathbf{v}_1 \otimes \mathbf{v}_2) \otimes \mathbf{v}_3, \mathbf{v}_i \in V_i$, $i = 1, 2, 3$ (respectively $\mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3 = \mathbf{v}_1 \otimes (\mathbf{v}_2 \otimes \mathbf{v}_3), \mathbf{v}_i \in V_i$, $i = 1, 2, 3$).

In general, with an analogous meaning,

$$(W_1 \otimes \cdots \otimes W_p) \otimes (V_1 \otimes \cdots \otimes V_q) = W_1 \otimes \cdots \otimes W_p \otimes V_1 \otimes \cdots \otimes V_q.$$

13. Let W_i be a subspace of V_i, $i = 1, \ldots, m$. Then $W_1 \otimes \cdots \otimes W_m$ is a subspace of $V_1 \otimes \cdots \otimes V_m$, meaning that the subspace of $V_1 \otimes \cdots \otimes V_m$ spanned by the set of decomposable tensors of the form

$$\mathbf{w}_1 \otimes \cdots \otimes \mathbf{w}_m, \quad \mathbf{w}_i \in W_i,\ i = 1, \ldots, m$$

is a tensor product of $W_1, \ldots, W_m$ with tensor multiplication equal to the restriction of $\otimes$ to $W_1 \times \cdots \times W_m$.

From now on, the model for the tensor product described above is assumed when dealing with the tensor product of subspaces of V_i.

14. Let W_1, W_1' be subspaces of V_1 and W_2 and W_2' be subspaces of V_2. Then

(a) $(W_1 \otimes W_2) \cap (W_1' \otimes W_2') = (W_1 \cap W_1') \otimes (W_2 \cap W_2')$.

(b) $W_1 \otimes (W_2 + W_2') = (W_1 \otimes W_2) + (W_1 \otimes W_2')$,
$(W_1 + W_1') \otimes W_2 = (W_1 \otimes W_2) + (W_1' \otimes W_2)$.

(c) Assuming $W_1 \cap W_1' = \{0\}$,
$(W_1 \oplus W_1') \otimes W_2 = (W_1 \otimes W_2) \oplus (W_1' \otimes W_2)$.

Assuming $W_2 \cap W_2' = \{0\}$,
$W_1 \otimes (W_2 \oplus W_2') = (W_1 \otimes W_2) \oplus (W_1 \otimes W_2')$.

15. In a more general setting, if W_{ij}, $j = 1, \ldots, p_i$ are subspaces of V_i, $i \in \{1, \ldots, m\}$, then

$$\left(\sum_{j=1}^{p_1} W_{1j}\right) \otimes \cdots \otimes \left(\sum_{j=1}^{p_m} W_{1j}\right) = \sum_{\gamma \in \Gamma(p_1 \cdots p_m)} W_{1\gamma(1)} \otimes \cdots \otimes W_{m\gamma(m)}.$$

If the sums of subspaces in the left-hand side are direct, then

$$\left(\bigoplus_{j=1}^{p_1} W_{1j}\right) \otimes \cdots \otimes \left(\bigoplus_{j=1}^{p_m} W_{1j}\right) = \bigoplus_{\gamma \in \Gamma(p_1, \ldots, p_m)} W_{1\gamma(1)} \otimes \cdots \otimes W_{m,\gamma(m)}.$$

Examples:

1. The vector space $F^{m \times n}$ of the $m \times n$ matrices over F is a tensor product of F^m and F^n with tensor multiplication (the usual tensor multiplication for $F^{m \times n}$) defined, for $(a_1, \ldots, a_m) \in F^m$ and $(b_1, \ldots, b_n) \in F^n$, by

$$(a_1, \ldots, a_m) \otimes (b_1, \ldots, b_n) = \begin{bmatrix} a_1 \\ \vdots \\ a_m \end{bmatrix} \begin{bmatrix} b_1 & \cdots & b_n \end{bmatrix}.$$

With this definition, $\mathbf{e}_i \otimes \mathbf{e}'_j = E_{ij}$ where $(\mathbf{e}_i)$, $(\mathbf{e}'_j)$, and (E_{ij}) are standard basis vectors of F^m, F^n, and $F^{m\times n}$.

2. The field F, viewed as a vector space over F, is an mth tensor power of F with tensor multiplication defined by
$$a_1 \otimes \cdots \otimes a_m = \prod_{i=1}^{m} a_i, \quad a_i \in F, \quad i = 1, \ldots, m.$$
3. The vector space V is a tensor product of F and V with tensor multiplication defined by
$$a \otimes \mathbf{v} = a\mathbf{v}, \quad a \in F, \quad \mathbf{v} \in V.$$
4. Let U and V be vector spaces over F. Then $L(V;U)$ is a tensor product $U \otimes V^*$ with tensor multiplication (the usual tensor multiplication in $L(V;U)$) defined by the equality $(\mathbf{u} \otimes f)(\mathbf{v}) = f(\mathbf{v})\mathbf{u}$, $\mathbf{u} \in U, \mathbf{v} \in V$.
5. Let $V_1, \ldots, V_m$ be vector spaces over F. The vector space $L(V_1, \ldots, V_m; U)$ is a tensor product $L(V_1, \ldots, V_m; F) \otimes U$ with tensor multiplication
$$(\varphi \otimes \mathbf{u})(\mathbf{v}_1, \ldots, \mathbf{v}_m) = \varphi(\mathbf{v}_1, \ldots, \mathbf{v}_m)\mathbf{u}.$$
6. Denote by $F^{n_1\times\cdots\times n_m}$ the set of all families with elements of F indexed in $\{1, \ldots, n_1\} \times \cdots \times \{1, \ldots, n_m\} = \Gamma(n_1, \ldots, n_m)$. The set $F^{n_1\times\cdots\times n_m}$ equipped with the sum and scalar product defined, for every $\alpha \in \Gamma(n_1, \ldots, n_m)$, by the equalities
$$\begin{aligned}(a_\alpha) + (b_\alpha) &= (a_\alpha + b_\alpha),\\ a(a_\alpha) &= (aa_\alpha), \quad a \in F,\end{aligned}$$
is a vector space over F. This vector space is a tensor product of $F^{n_1}, \ldots, F^{n_m}$ with tensor multiplication defined by
$$(a_{11}, \ldots, a_{1n_1}) \otimes \cdots \otimes (a_{m1}, \ldots, a_{mn_m}) = \left(\prod_{i=1}^{m} a_{i\alpha(i)}\right)_{\alpha\in\Gamma}.$$
7. The vector space $L(V_1, \ldots, V_m; F)$ is a tensor product of $V_1^* = L(V_1; F), \ldots, V_m^* = L(V_m; F)$ with tensor multiplication defined by
$$g_1 \otimes \cdots \otimes g_m(\mathbf{v}_1, \ldots, \mathbf{v}_m) = \prod_{t=1}^{m} g_t(\mathbf{v}_t).$$
Very often, for example in the context of geometry, the factors of the tensor product are vector space duals. In those situations, this is the model of tensor product implicitly assumed.
8. The vector space
$$L(V_1, \ldots, V_m; F)^*$$
is a tensor product of $V_1, \ldots, V_m$ with tensor multiplication defined by
$$\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m(\psi) = \psi(\mathbf{v}_1, \ldots, \mathbf{v}_m).$$
9. The vector space $L(W_1, \ldots, W_p, V_1, \ldots, V_q; F)$ is a tensor product
$$L(W_1, \ldots, W_p; F) \otimes L(V_1, \ldots, V_q; F)$$
with tensor multiplication defined, for every $\mathbf{w}_i$, in W_i, $\mathbf{v}_j$ in V_j, $i = 1, \ldots, p$, $j = 1, \ldots, q$, by the equalities
$$(\varphi \otimes \psi)(\mathbf{w}_1, \ldots, \mathbf{w}_p, \mathbf{v}_1, \ldots, \mathbf{v}_q) = \varphi(\mathbf{w}_1, \ldots, \mathbf{w}_p)\psi(\mathbf{v}_1, \ldots, \mathbf{v}_q).$$

14.3 Rank of a Tensor: Decomposable Tensors

Definitions:

Let $\mathbf{z} \in V_1 \otimes \cdots \otimes V_m$. The tensor $\mathbf{z}$ has **rank** k if $\mathbf{z}$ is the sum of k decomposable tensors but it cannot be written as the sum of l decomposable tensors, for any l less than k.

Facts:

The following facts can be found in [Bou89, Chap. II, §7.8] and [Mar73, Chap. 1].

1. The tensor $z = \mathbf{v}_1 \otimes \mathbf{w}_1 + \cdots + \mathbf{v}_t \otimes \mathbf{w}_t \in V \otimes W$ has rank t if and only if $(\mathbf{v}_1, \ldots, \mathbf{v}_t)$ and $(\mathbf{w}_1, \ldots, \mathbf{w}_t)$ are linearly independent.
2. If the model for the tensor product of F^m and F^n is the vector space of $m \times n$ matrices over F with the usual tensor multiplication, then the rank of a tensor is equal to the rank of the corresponding matrix.
3. If the model for the tensor product $U \otimes V^*$ is the vector space $L(V; U)$ with the usual tensor multiplication, then the rank of a tensor is equal to the rank of the corresponding linear map.
4. $\mathbf{x}_1 \otimes \cdots \otimes \mathbf{x}_m = 0$ if and only if $\mathbf{x}_i = 0$ for some $i \in \{1, \ldots, m\}$.
5. If $\mathbf{x}_i, \mathbf{y}_i$ are nonzero vectors of V_i, $i = 1, \ldots, m$, then

$$\mathrm{Span}(\{\mathbf{x}_1 \otimes \cdots \otimes \mathbf{x}_m\}) = \mathrm{Span}(\{\mathbf{y}_1 \otimes \cdots \otimes \mathbf{y}_m\})$$

   if and only if $\mathrm{Span}(\{\mathbf{x}_i\}) = \mathrm{Span}(\{\mathbf{y}_i\})$, $i = 1, \ldots, m$.

Examples:

1. Consider as a model of $F^m \otimes F^n$, the vector space of the $m \times n$ matrices over F with the usual tensor multiplication. Let A be a tensor of $F^m \otimes F^n$. If rank $A = k$ (using the matrix definition of rank), then

$$A = M \begin{bmatrix} I_k & 0 \\ 0 & 0 \end{bmatrix} N,$$

   where $M = [\mathbf{x}_1 \cdots \mathbf{x}_m]$ is an invertible matrix with columns $\mathbf{x}_1, \ldots, \mathbf{x}_m$ and

$$N = \begin{bmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \\ \vdots \\ \mathbf{y}_n \end{bmatrix}$$

   is an invertible matrix with rows $\mathbf{y}_1, \ldots, \mathbf{y}_n$. (See Chapter 2.) Then

$$A = \mathbf{x}_1 \otimes \mathbf{y}_1 + \cdots + \mathbf{x}_k \otimes \mathbf{y}_k$$

   has rank k as a tensor.

14.4 Tensor Product of Linear Maps

Definitions:

Let θ_i be a linear map from V_i into U_i, $i = 1, \ldots, m$. The unique linear map h from $V_1 \otimes \cdots \otimes V_m$ into $U_1 \otimes \cdots \otimes U_m$ satisfying, for all $\mathbf{v}_i \in V_i, i = 1, \ldots, m$,

$$h(\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m) = \theta_1(\mathbf{v}_1) \otimes \cdots \otimes \theta_m(\mathbf{v}_m)$$

is called the **tensor product** of $\theta_1, \ldots, \theta_m$ and is denoted by $\theta_1 \otimes \cdots \otimes \theta_m$.

Let $A_t = (a_{ij}^{(t)})$ be an $r_t \times s_t$ matrix over F, $t = 1, \ldots, m$. The **Kronecker product** of $A_1, \ldots, A_m$, denoted $A_1 \otimes \cdots \otimes A_m$, is the $(\prod_{t=1}^{m} r_t) \times (\prod_{t=1}^{m} s_t)$ matrix whose (α, β)-entry ($\alpha \in \Gamma(r_1, \ldots, r_m)$ and $\beta \in \Gamma(s_1, \ldots, s_m)$) is $\prod_{t=1}^{m} a_{\alpha(t)\beta(t)}^{(t)}$. (See also Section 11.4.)

Facts:

The following facts can be found in [Mar73, Chap. 2] and [Mer97, Chap. 5].

Let θ_i be a linear map from V_i into U_i, $i = 1, \ldots, m$.

1. If η_i is a linear map from W_i into V_i, $i = 1, \ldots, m$,
$$(\theta_1 \otimes \cdots \otimes \theta_m)(\eta_1 \otimes \cdots \otimes \eta_m) = (\theta_1\eta_1) \otimes \cdots \otimes (\theta_m\eta_m).$$
2. $I_{V_1 \otimes \cdots \otimes V_m} = I_{V_1} \otimes \cdots \otimes I_{V_m}$.
3. $\mathrm{Ker}(\theta_1 \otimes \cdots \otimes \theta_m) = \mathrm{Ker}(\theta_1) \otimes V_2 \otimes \cdots \otimes V_m + V_1 \otimes \mathrm{Ker}(\theta_2) \otimes \cdots \otimes V_m + \cdots + V_1 \otimes \cdots \otimes V_{m-1} \otimes \mathrm{Ker}(\theta_m)$.
In particular, $\theta_1 \otimes \cdots \otimes \theta_m$ is one to one if θ_i is one to one, $i = 1, \ldots, m$, [Bou89, Chap. II, 3.5].
4. $\theta_1 \otimes \cdots \otimes \theta_m(V_1 \otimes \cdots \otimes V_m) = \theta_1(V_1) \otimes \cdots \otimes \theta_m(V_m)$. In particular $\theta_1 \otimes \cdots \otimes \theta_m$ is onto if θ_i is onto, $i = 1, \ldots, m$.

In the next three facts, assume that θ_i is a linear operator on the n_i-dimensional vector space V_i, $i = 1, \ldots, m$.

5. $\mathrm{tr}(\theta_1 \otimes \cdots \otimes \theta_m) = \prod_{i=1}^{m} \mathrm{tr}(\theta_i)$.
6. If $\sigma(\theta_i) = \{a_{i1}, \ldots, a_{in_i}\}$, $i = 1, \ldots, m$, then
$$\sigma(\theta_1 \otimes \cdots \otimes \theta_m) = \left\{ \prod_{i=1}^{m} a_{i,\alpha(i)} \right\}_{\alpha \in \Gamma(n_1, \ldots, n_m)}.$$
7. $\det(\theta_1 \otimes \theta_2 \otimes \cdots \otimes \theta_m) = \det(\theta_1)^{n_2 \cdots n_m} \det(\theta_2)^{n_1 \cdot n_3 \cdots n_m} \cdots \det(\theta_m)^{n_1 \cdot n_2 \cdots n_{m-1}}$.
8. The map $\nu : (\theta_1, \ldots, \theta_m) \mapsto \theta_1 \otimes \cdots \otimes \theta_m$ is a multilinear map from $L(V_1; U_1) \times \cdots \times L(V_m; U_m)$ into $L(V_1 \otimes \cdots \otimes V_m; U_1 \otimes \cdots \otimes U_m)$.
9. The vector space $L(V_1 \otimes \cdots \otimes V_m; U_1 \otimes \cdots \otimes U_m))$ is a tensor product of the vector spaces $L(V_1; U_1), \ldots, L(V_m; U_m)$, with tensor multiplication $(\theta_1, \ldots, \theta_m) \mapsto \theta_1 \otimes \cdots \otimes \theta_m$:
$$L(V_1; U_1) \otimes \cdots \otimes L(V_m; U_m) = L(V_1 \otimes \cdots \otimes V_m; U_1 \otimes \cdots \otimes U_m).$$
10. As a consequence of Fact 9, choosing F as the model for $\bigotimes^m F$ with the product in F as tensor multiplication,
$$V_1^* \otimes \cdots \otimes V_m^* = (V_1 \otimes \cdots \otimes V_m)^*.$$
11. Let $(\mathbf{v}_{ij})_{j=1,\ldots,n_i}$ be an ordered basis of V_i and $(\mathbf{u}_{ij})_{j=1,\ldots,q_i}$ an ordered basis of U_i, $i = 1, \ldots, m$. Let A_i be the matrix of θ_i on the bases fixed in V_i and U_i. Then the matrix of $\theta_1 \otimes \cdots \otimes \theta_m$ on the bases $(\mathbf{v}_\alpha^\otimes)_{\alpha \in \Gamma(n_1, \ldots, n_m)}$ and $(\mathbf{u}_\alpha^\otimes)_{\alpha \in \Gamma(q_1, \ldots, q_r)}$ (induced by the bases $(\mathbf{v}_{ij})_{j=1,\ldots,n_i}$ and $(\mathbf{u}_{ij})_{j=1,\ldots,q_i}$, respectively) is the Kronecker product of $A_1, \ldots, A_m$,
$$A_1 \otimes \cdots \otimes A_m.$$
12. Let $n_1, \ldots, n_m, r_1, \ldots, r_m, t_1, \ldots, t_m$ be positive integers. Let A_i be an $n_i \times r_i$ matrix, and B_i be an $r_i \times t_i$ matrix, $i = 1, \ldots, m$. Then the following holds:
   (a) $(A_1 \otimes \cdots \otimes A_m)(B_1 \otimes \cdots \otimes B_m) = A_1B_1 \otimes \cdots \otimes A_mB_m$,

(b) $(A_1 \otimes \cdots \otimes A_k) \otimes (A_{k+1} \otimes \cdots \otimes A_m) = A_1 \otimes \cdots \otimes A_m$.

Examples:

1. Consider as a model of $U \otimes V^*$, the vector space $L(V;U)$ with tensor multiplication defined by $(\mathbf{u} \otimes f)(\mathbf{v}) = f(\mathbf{v})\mathbf{u}$. Use a similar model for the tensor product of U' and V'^*. Let $\eta \in L(U;U')$ and $\theta \in L(V^{'};V)$. Then, for all $\xi \in U \otimes V^* = L(V;U)$,
$$\eta \otimes \theta^*(\xi) = \eta\xi\theta.$$
2. Consider as a model of $F^m \otimes F^n$, the vector space of the $m \times n$ matrices over F with the usual tensor multiplication. Use a similar model for the tensor product of F^r and F^s. Identify the set of column matrices, $F^{m\times 1}$, with F^m and the set of row matrices, $F^{1\times n}$, with F^n. Let A be an $r \times m$ matrix over F. Let θ_A be the linear map from F^m into F^r defined by
$$\theta_A(a_1, \ldots, a_m) = A \begin{bmatrix} a_1 \\ a_2 \\ \vdots \\ a_m \end{bmatrix}.$$
Let B be an $s \times n$ matrix. Then, for all $C \in F^{m\times n} = F^m \otimes F^n$, $\theta_A \otimes \theta_B(C) = ACB^T$.
3. For every $i = 1, \ldots, m$ consider the ordered basis $(\mathbf{b}_{i1}, \ldots, \mathbf{b}_{in_i})$ fixed in V_i, and the basis $(\mathbf{b}'_{i1}, \ldots, \mathbf{b}'_{is_i})$ fixed in U_i. Let θ_i be a linear map from V_i into U_i and let $A_i = (a^{(i)}_{jk})$ be the $s_i \times n_i$ matrix of θ_i with respect to the bases $(\mathbf{b}_{i1}, \ldots, \mathbf{b}_{in_i})$, $(\mathbf{b}'_{i1}, \ldots, \mathbf{b}'_{is_i})$. For every $z \in V_1 \otimes \cdots \otimes V_m$,
$$\begin{aligned} z &= \sum_{j_1=1}^{n_1} \sum_{j_2=1}^{n_2} \cdots \sum_{j_m=1}^{n_m} c_{j_1,\ldots,j_m} \mathbf{b}_{1j_1} \otimes \cdots \otimes \mathbf{b}_{m,j_m} \\ &= \sum_{\alpha\in\Gamma(n_1,\ldots,n_m)} c_\alpha \mathbf{b}^{\otimes}_{\alpha}. \end{aligned}$$
Then, for $\beta = (i_1, \ldots, i_m) \in \Gamma(s_1, \ldots, s_m)$, the component $c'_{i_1,\ldots,i_m}$ of $\theta_1 \otimes \cdots \otimes \theta_m(z)$ on the basis element $\mathbf{b}'_{1i_1} \otimes \cdots \otimes \mathbf{b}'_{mi_m}$ of $U_1 \otimes \cdots \otimes U_m$ is
$$\begin{aligned} c'_\beta = c'_{i_1,\ldots,i_m} &= \sum_{j_1=1}^{n_1} \cdots \sum_{j_m=1}^{n_m} a^{(1)}_{i_1,j_1} \cdots a^{(m)}_{i_m,j_m} c_{j_1,\ldots,j_m} \\ &= \sum_{\gamma\in\Gamma(n_1,\ldots,n_m)} \left(\prod_{i=1}^{m} a^{(i)}_{\beta(i)\gamma(i)} \right) c_\gamma. \end{aligned}$$
4. If $A = [a_{ij}]$ is a $p \times q$ matrix over F and B is an $r \times s$ matrix over F, then the Kronecker product of A and B is the matrix whose partition in $r \times s$ blocks is
$$A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B & \cdots & a_{1q}B \\ a_{21}B & a_{22}B & \cdots & a_{2q}B \\ \vdots & \vdots & \ddots & \vdots \\ a_{p1}B & a_{p2}B & \cdots & a_{pq}B \end{bmatrix}.$$

14.5 Symmetric and Antisymmetric Maps

Recall that we are assuming F to be of characteristic zero and that all vector spaces are finite dimensional over F. In particular, V and U denote finite dimensional vector spaces over F.

Definitions:

Let m be a positive integer. The notation $L^m(V;U)$ for the vector space of the multilinear maps $L(V_1,\dots,V_m;U)$, will be used when $V_1 = V_2 = \cdots = V_m = V$. By convention $L^0(V;U) = U$.

An m-linear map $\psi \in L^m(V;U)$ is called **antisymmetric or alternating** if, for all permutations $\sigma \in S_m$ and for all $\mathbf{v}_1,\dots,\mathbf{v}_m$ in V, it satisfies

$$\psi(\mathbf{v}_{\sigma(1)},\dots,\mathbf{v}_{\sigma(m)}) = \operatorname{sgn}(\sigma)\psi(\mathbf{v}_1,\dots,\mathbf{v}_m),$$

where $\operatorname{sgn}(\sigma)$ denotes the sign of the permutation σ.

Similarly, an m-linear map $\varphi \in L^m(V;U)$ satisfying

$$\varphi(\mathbf{v}_{\sigma(1)},\dots,\mathbf{v}_{\sigma(m)}) = \varphi(\mathbf{v}_1,\dots,\mathbf{v}_m)$$

for all permutations $\sigma \in S_m$ and for all $\mathbf{v}_1,\dots,\mathbf{v}_m$ in V is called **symmetric**. Let $S^m(V;U)$ and $A^m(V;U)$ denote the subsets of $L^m(V;U)$ whose elements are, respectively, the symmetric and the antisymmetric m-linear maps. The elements of $A^m(V;F)$ are called **antisymmetric forms**. The elements of $S^m(V;F)$ are called **symmetric forms**.

Let $\Gamma_{m,n}$ be the set of all maps from $\{1,\dots,m\}$ into $\{1,\dots,n\}$, i.e.,

$$\Gamma_{m,n} = \Gamma\underbrace{(n,\dots,n)}_{m\text{ times}}.$$

The subset of $\Gamma_{m,n}$ of the strictly increasing maps α ($\alpha(1) < \cdots < \alpha(m)$) is denoted by $Q_{m,n}$. The subset of the increasing maps $\alpha \in \Gamma_{m,n}$ ($\alpha(1) \le \cdots \le \alpha(m)$) is denoted by $G_{m,n}$.

Let $A = [a_{ij}]$ be an $m \times n$ matrix over F. Let $\alpha \in \Gamma_{p,m}$ and $\beta \in \Gamma_{q,n}$. Then $A[\alpha|\beta]$ is the $p \times q$-matrix over F whose (i,j)-entry is $a_{\alpha(i),\beta(j)}$, i.e.,

$$A[\alpha|\beta] = [a_{\alpha(i),\beta(j)}].$$

The mth-tuple $(1,2,\dots,m)$ is denoted by ι_m. If there is no risk of confusion, ι is used instead of ι_m.

Facts:

1. If $m > n$, we have $Q_{m,n} = \emptyset$. The cardinality of $\Gamma_{m,n}$ is n^m, the cardinality of $Q_{m,n}$ is $\binom{n}{m}$, and the cardinality of $G_{m,n}$ is $\binom{m+n-1}{m}$.
2. $A^m(V;U)$ and $S^m(V;U)$ are vector subspaces of $L^m(V;U)$.
3. Let $\psi \in L^m(V;U)$. The following conditions are equivalent:
   (a) ψ is an antisymmetric multilinear map.
   (b) For $1 \le i < j \le m$ and for all $\mathbf{v}_1,\dots,\mathbf{v}_m \in V$,

$$\begin{aligned}\psi(&\mathbf{v}_1,\dots,\mathbf{v}_{i-1},\mathbf{v}_j,\mathbf{v}_{i+1},\dots,\mathbf{v}_{j-1},\mathbf{v}_i,\mathbf{v}_{j+1},\dots,\mathbf{v}_m)\\ &= -\psi(\mathbf{v}_1,\dots,\mathbf{v}_{i-1},\mathbf{v}_i,\mathbf{v}_{i+1},\dots,\mathbf{v}_{j-1},\mathbf{v}_j,\mathbf{v}_{j+1},\dots,\mathbf{v}_m).\end{aligned}$$

(c) For $1 \leq i < m$ and for all $\mathbf{v}_1, \ldots, \mathbf{v}_m \in V$,

$$\psi(\mathbf{v}_1, \ldots, \mathbf{v}_{i+1}, \mathbf{v}_i, \ldots, \mathbf{v}_m) = -\psi(\mathbf{v}_1, \ldots, \mathbf{v}_i, \mathbf{v}_{i+1}, \ldots, \mathbf{v}_m).$$

4. Let $\psi \in L^m(V; U)$. The following conditions are equivalent:
   (a) ψ is a symmetric multilinear map.
   (b) For $1 \leq i < j \leq m$ and for all $\mathbf{v}_1, \ldots, \mathbf{v}_m \in V$,

$$\begin{aligned}\psi(\mathbf{v}_1, \ldots, \mathbf{v}_{i-1}, \mathbf{v}_j, \mathbf{v}_{i+1}, \ldots, \mathbf{v}_{j-1}, \mathbf{v}_i, \mathbf{v}_{j+1}, \ldots, \mathbf{v}_m)\\ = \psi(\mathbf{v}_1, \ldots, \mathbf{v}_{i-1}, \mathbf{v}_i, \mathbf{v}_{i+1}, \ldots, \mathbf{v}_{j-1}, \mathbf{v}_j, \mathbf{v}_{j+1}, \ldots, \mathbf{v}_m).\end{aligned}$$

   (c) For $1 \leq i < m$ and for all $\mathbf{v}_1, \ldots, \mathbf{v}_m \in V$,

$$\psi(\mathbf{v}_1, \ldots, \mathbf{v}_{i+1}, \mathbf{v}_i, \ldots, \mathbf{v}_m) = \psi(\mathbf{v}_1, \ldots, \mathbf{v}_i, \mathbf{v}_{i+1}, \ldots, \mathbf{v}_m).$$

5. When we consider $L^m(V; U)$ as the tensor product, $L^m(V; F) \otimes U$, with the tensor multiplication described in Example 14.2.5, we have

$$A^m(V; U) = A^m(V; F) \otimes U \quad \text{and} \quad S^m(V; U) = S^m(V; F) \otimes U.$$

6. [Dol04] (*Polarization identity*) If φ is a symmetric multilinear map, then for every m-tuple $(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ of vectors of V, and for any vector $\mathbf{w} \in V$, the following identity holds:

$$\begin{aligned}&\varphi(\mathbf{v}_1, \ldots, \mathbf{v}_m) =\\ &= \frac{1}{2^m m!} \sum_{\varepsilon_1 \cdots \varepsilon_m} \varepsilon_1 \cdots \varepsilon_m \varphi(\mathbf{w} + \varepsilon_1 \mathbf{v}_1 + \cdots + \varepsilon_m \mathbf{v}_m, \ldots, \mathbf{w} + \varepsilon_1 \mathbf{v}_1 + \cdots + \varepsilon_m \mathbf{v}_m),\end{aligned}$$

   where $\varepsilon_i \in \{-1, +1\}$, $i = 1, \ldots, m$.

Examples:

1. The map

$$((a_{11}, a_{21}, \ldots, a_{m1}), \ldots, (a_{1m}, a_{2m}, \ldots, a_{mm})) \to \det([a_{ij}])$$

   from the Cartesian product of m copies of F^m into F is m-linear and antisymmetric.
2. The map

$$((a_{11}, a_{21}, \ldots, a_{m1}), \ldots, (a_{1m}, a_{2m}, \ldots, a_{mm})) \to \operatorname{per}([a_{ij}])$$

   from the Cartesian product of m copies of F^m into F is m-linear and symmetric.
3. The map $((a_1, \ldots, a_n), (b_1, \ldots, b_n)) \mapsto (a_i b_j - b_i a_j)$ from $F^n \times F^n$ into $F^{n \times n}$ is bilinear antisymmetric.
4. The map $((a_1, \ldots, a_n), (b_1, \ldots, b_n)) \mapsto (a_i b_j + b_i a_j)$ from $F^n \times F^n$ into $F^{n \times n}$ is bilinear symmetric.
5. The map χ from V^m into $A^m(V; F)^*$ defined by

$$\chi(\mathbf{v}_1, \ldots, \mathbf{v}_m)(\psi) = \psi(\mathbf{v}_1, \ldots, \mathbf{v}_m), \quad \mathbf{v}_1, \ldots, \mathbf{v}_m \in V,$$

   is an antisymmetric multilinear map.
6. The map χ from V^m into $S^m(V; F)^*$ defined by

$$\chi(\mathbf{v}_1, \ldots, \mathbf{v}_m)(\psi) = \psi(\mathbf{v}_1, \ldots, \mathbf{v}_m), \quad \mathbf{v}_1, \ldots, \mathbf{v}_m \in V,$$

   is a symmetric multilinear map.

14.6 Symmetric and Grassmann Tensors

Definitions:

Let $\sigma \in S_m$ be a permutation of $\{1, \ldots, m\}$. The unique linear map, from $\otimes^m V$ into $\otimes^m V$ satisfying

$$\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m \mapsto \mathbf{v}_{\sigma^{-1}(1)} \otimes \cdots \otimes \mathbf{v}_{\sigma^{-1}(m)}, \quad \mathbf{v}_1, \ldots, \mathbf{v}_m \in V,$$

is denoted $P(\sigma)$.

Let ψ be a multilinear map in $L^m(V; U)$ and σ an element of S_m . The multilinear map $(\mathbf{v}_1, \ldots, \mathbf{v}_m) \mapsto \psi(\mathbf{v}_{\sigma(1)}, \ldots, \mathbf{v}_{\sigma(m)})$ is denoted ψ_σ.

The linear operator Alt from $\bigotimes^m V$ into $\bigotimes^m V$ defined by

$$\mathrm{Alt} = \frac{1}{m!} \sum_{\sigma \in S_m} \mathrm{sgn}(\sigma) P(\sigma)$$

is called the **alternator**. In order to emphasize the degree of the domain of Alt, Alt_m is often used for the operator having $\bigotimes^m V$ as domain.

Similarly, the linear operator Sym is defined as the following linear combination of the maps $P(\sigma)$:

$$\mathrm{Sym} = \frac{1}{m!} \sum_{\sigma \in S_m} P(\sigma).$$

As before, Sym_m is often written to mean the Sym operator having $\bigotimes^m V$ as domain.

The range of Alt is denoted by $\bigwedge^m V$, i.e., $\bigwedge^m V = \mathrm{Alt}(\bigotimes^m V)$, and is called the **Grassmann space of degree** m associated with V or the m**th-exterior power** of V.

The range of Sym is denoted by $\bigvee^m V$, i.e., $\bigvee^m V = \mathrm{Sym}(\bigotimes^m V)$, and is called the **symmetric space of degree** m associated with V or the m**th symmetric power** of V.

By convention

$$\bigotimes^0 V = \bigwedge^0 V = \bigvee^0 V = F.$$

Assume $m \geq 1$. The elements of $\bigwedge^m V$ that are the image under Alt of decomposable tensors of $\bigotimes^m V$ are called **decomposable elements of** $\bigwedge^m V$. If $\mathbf{x}_1, \ldots, \mathbf{x}_m \in V$, $\mathbf{x}_1 \wedge \cdots \wedge \mathbf{x}_m$ denotes the decomposable element of $\bigwedge^m V$,

$$\mathbf{x}_1 \wedge \cdots \wedge \mathbf{x}_m = m!\mathrm{Alt}(\mathbf{x}_1 \otimes \cdots \otimes \mathbf{x}_m),$$

and $\mathbf{x}_1 \wedge \cdots \wedge \mathbf{x}_m$ is called the **exterior product** of $\mathbf{x}_1, \ldots, \mathbf{x}_m$. Similarly, the elements of $\bigvee^m V$ that are the image under Sym of decomposable tensors of $\bigotimes^m V$ are called **decomposable elements of** $\bigvee^m V$. If $\mathbf{x}_1, \ldots, \mathbf{x}_m \in V$, $\mathbf{x}_1 \vee \cdots \vee \mathbf{x}_m$ denotes the decomposable element of $\bigvee^m V$,

$$\mathbf{x}_1 \vee \cdots \vee \mathbf{x}_m = m!\mathrm{Sym}(\mathbf{x}_1 \otimes \cdots \otimes \mathbf{x}_m),$$

and $\mathbf{x}_1 \vee \cdots \vee \mathbf{x}_m$ is called the **symmetric product** of $\mathbf{x}_1, \ldots, \mathbf{x}_m$.

Let $(\mathbf{b}_1, \ldots, \mathbf{b}_n)$ be a basis of V. If $\alpha \in \Gamma_{m,n}$, $\mathbf{b}_\alpha^\otimes$, $\mathbf{b}_\alpha^\wedge$, and $\mathbf{b}_\alpha^\vee$ denote, respectively, the tensors

$$\mathbf{b}_\alpha^\otimes = \mathbf{b}_{\alpha(1)} \otimes \cdots \otimes \mathbf{b}_{\alpha(m)},$$
$$\mathbf{b}_\alpha^\wedge = \mathbf{b}_{\alpha(1)} \wedge \cdots \wedge \mathbf{b}_{\alpha(m)},$$
$$\mathbf{b}_\alpha^\vee = \mathbf{b}_{\alpha(1)} \vee \cdots \vee \mathbf{b}_{\alpha(m)}.$$

Let n and m be positive integers. An n**-composition** of m is a sequence

$$\mu = (\mu_1, \ldots, \mu_n)$$

of nonnegative integers that sum to m. Let $\mathcal{C}_{m,n}$ be the set of n-compositions of m.

Let $\lambda = (\lambda_1, \dots, \lambda_n)$ be an n-composition of m. The integer $\lambda_1! \cdots \lambda_n!$ will be denoted by $\lambda!$.

Let $\alpha \in \Gamma_{m,n}$. The **multiplicity composition** of α is the n-tuple of the cardinalities of the fibers of α, $(|\alpha^{-1}(1)|, \dots, |\alpha^{-1}(n)|)$, and is denoted by λ_α.

Facts:

The following facts can be found in [Mar73, Chap. 2], [Mer97, Chap. 5], and [Spi79, Chap. 7].

1. $\bigwedge^m V$ and $\bigvee^m V$are vector subspaces of $\bigotimes^m V$.
2. The map $\sigma \mapsto P(\sigma)$ from the symmetric group of degree m into $L(\otimes^m V; \otimes^m V)$ is an F-representation of S_m, i.e., $P(\sigma\tau) = P(\sigma)P(\tau)$ for any $\sigma, \tau \in S_m$ and $P(I) = I_{\otimes^m V}$.
3. Choosing $L^m(V; F)$, with the usual tensor multiplication, as the model for the tensor power, $\bigotimes^m V^*$, the linear operator $P(\sigma)$ acts on $L^m(V; F)$ by the following transformation:
$$P(\sigma)(\psi) = \psi_\sigma.$$
4. The linear operators Alt and Sym are projections, i.e., $\mathrm{Alt}^2 = \mathrm{Alt}$ and $\mathrm{Sym}^2 = \mathrm{Sym}$.
5. If $m = 1$, we have
$$\mathrm{Sym} = \mathrm{Alt} = I_{\bigotimes^1 V} = I_V.$$
6. $\bigwedge^m V = \{\mathbf{z} \in \bigotimes^m V \ : \ P(\sigma)(z) = \mathrm{sgn}(\sigma)z, \ \forall \sigma \in S_m\}$.
7. $\bigvee^m V = \{\mathbf{z} \in \bigotimes^m V \ : \ P(\sigma)(z) = z, \ \forall \sigma \in S_m\}$.
8. Choosing $L^m(V; F)$ as the model for the tensor power $\bigotimes^m V^*$ with the usual tensor multiplication,
$$\bigwedge^m V^* = A^m(V; F) \quad \text{and} \quad \bigvee^m V^* = S^m(V; F).$$
9. $$\bigotimes^1 V = \bigwedge^1 V = \bigvee^1 V = V.$$
10. $\bigotimes^2 V = \bigwedge^2 V \oplus \bigvee^2 V$. Moreover, for $z \in \bigotimes^2 V$,
$$\mathbf{z} = \mathrm{Alt}\,(\mathbf{z}) + \mathrm{Sym}\,(\mathbf{z}).$$
    The corresponding equality is no more true in $\bigotimes^m V$ if $m \neq 2$.
11. $\bigwedge^m V = \{0\}$ if $m > \dim(V)$.
12. If $m \geq 1$, any element of $\bigotimes^m V$ is a sum of decomposable elements of $\bigotimes^m V$.
13. If $m \geq 1$, any element of $\bigwedge^m V$ is a sum of decomposable elements of $\bigwedge^m V$.
14. If $m \geq 1$, any element of $\bigvee^m V$ is a sum of decomposable elements of $\bigvee^m V$.
15. $\mathrm{Alt}\,(P(\sigma)z) = \mathrm{sgn}(\sigma)\mathrm{Alt}\,(z)$ and $\mathrm{Sym}\,(P(\sigma)(z)) = \mathrm{Sym}\,(z)$, $z \in \bigotimes^m V$.
16. The map $\wedge$ from V^m into $\bigwedge^m V$ defined for $\mathbf{v}_1, \dots, \mathbf{v}_m \in V$ by
$$\wedge(\mathbf{v}_1, \dots, \mathbf{v}_m) = \mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m$$
    is an antisymmetric m-linear map.
17. The map $\vee$ from V^m into $\bigvee^m V$ defined for $\mathbf{v}_1, \dots, \mathbf{v}_m \in V$ by
$$\vee(\mathbf{v}_1, \dots, \mathbf{v}_m) = \mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m$$
    is a symmetric m-linear map.

18. (*Universal property for* $\bigwedge^m V$) Given an antisymmetric m-linear map ψ from V^m into U, there exists a unique linear map h from $\bigwedge^m V$ into U such that

$$\psi(\mathbf{v}_1, \ldots, \mathbf{v}_m) = h(\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m), \quad \mathbf{v}_1, \ldots, \mathbf{v}_m \in V,$$

i.e., there exists a unique linear map h that makes the following diagram commutative:

$$\begin{tikzcd} V^m \arrow[r, "\wedge"] \arrow[dr, "\psi"'] & \wedge^m V \arrow[d, "h"] \\ & U \end{tikzcd}$$

19. (*Universal property for* $\bigvee^m V$) Given a symmetric m-linear map φ from V^m into U, there exists a unique linear map h from $\bigvee^m V$ into U such that

$$\varphi(\mathbf{v}_1, \ldots, \mathbf{v}_m) = h(\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m), \quad \mathbf{v}_1, \ldots, \mathbf{v}_m \in V,$$

i.e., there exists a unique linear map h that makes the following diagram commutative:

$$\begin{tikzcd} V^m \arrow[r, "\vee"] \arrow[dr, "\varphi"'] & \vee^m V \arrow[d, "h"] \\ & U \end{tikzcd}$$

Let p and q be positive integers.

20. (*Universal property for* $\bigotimes^m V$*-bilinear version*) If ψ is a $(p+q)$-linear map from V^{p+q} into U, then there exists a unique bilinear map χ from $\bigotimes^p V \times \bigotimes^q V$ into U satisfying (recall Fact 14.2.5)

$$\chi(\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_p, \mathbf{v}_{p+1} \otimes \cdots \otimes \mathbf{v}_{p+q}) = \psi(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q}).$$

21. (*Universal property for* $\bigwedge^m V$*-bilinear version*) If ψ is a $(p+q)$-linear map from V^{p+q} into U antisymmetric in the first p variables and antisymmetric in the last q variables, then there exists a unique bilinear map χ from $\bigwedge^p V \times \bigwedge^q V$ into U satisfying

$$\chi(\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_p, \mathbf{v}_{p+1} \wedge \cdots \wedge \mathbf{v}_{p+q}) = \psi(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q}).$$

22. (*Universal property for* $\bigvee^m V$*-bilinear version*) If φ is a $(p+q)$-linear map from V^{p+q} into U symmetric in the first p variables and symmetric in the last q variables, then there exists a unique bilinear map χ from $\bigvee^p V \times \bigvee^q V$ into U satisfying

$$\chi(\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_p, \mathbf{v}_{p+1} \vee \cdots \vee \mathbf{v}_{p+q}) = \varphi(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q}).$$

23. If $(\mathbf{b}_1, \ldots, \mathbf{b}_n)$ is a basis of V, then $(\mathbf{b}^{\otimes}_{\alpha})_{\alpha \in \Gamma_{m,n}}$ is a basis of $\otimes^m V$, $(\mathbf{b}^{\wedge}_{\alpha})_{\alpha \in Q_{m,n}}$ is a basis of $\bigwedge^m V$, and $(\mathbf{b}^{\vee}_{\alpha})_{\alpha \in G_{m,n}}$ is a basis of $\bigvee^m V$. These bases are said to be *induced* by the basis $(\mathbf{b}_1, \ldots, \mathbf{b}_n)$.
24. Assume $L^m(V; F)$ as the model for the tensor power of $\bigotimes^m V^*$, with the usual tensor multiplication. Let $(f_1, \ldots, f_n)$ be the dual basis of the basis $(\mathbf{b}_1, \ldots, \mathbf{b}_n)$. Then:

    (a) For every $\varphi \in L^m(V; F)$,

$$\varphi = \sum_{\alpha \in \Gamma_{m,n}} \varphi(\mathbf{b}_\alpha) f^{\otimes}_{\alpha}.$$

(b) For every $\varphi \in A^m(V,F)$,

$$\varphi = \sum_{\alpha \in Q_{m,n}} \varphi(\mathbf{b}_\alpha) f_\alpha^\wedge.$$

(c) For every $\varphi \in S^m(V,F)$,

$$\varphi = \sum_{\alpha \in G_{m,n}} \frac{1}{\lambda_\alpha!} \varphi(\mathbf{b}_\alpha) f_\alpha^\vee.$$

25. $\dim \bigotimes^m V = n^m$, $\dim \bigwedge^m V = \binom{n}{m}$, and $\dim \bigvee^m V = \binom{n+m-1}{m}$.
26. The family

$$((\mu_1 \mathbf{b}_1 + \cdots + \mu_n \mathbf{b}_n) \vee \cdots \vee (\mu_1 \mathbf{b}_1 + \cdots + \mu_n \mathbf{b}_n))_{\mu \in \mathcal{C}_{m,n}}$$

is a basis of $\bigvee^m V$ [Mar73, Chap. 3].

27. Let $\mathbf{x}_1, \ldots, \mathbf{x}_m$ be vectors of V and $g_1, \ldots, g_m$ forms of V^*. Let $a_{ij} = g_i(\mathbf{x}_j),\ i,j = 1, \ldots, m$. Then, choosing $(\bigotimes^m V)^*$ as the model for $\bigotimes^m V^*$ with tensor multiplication as described in Fact 14.4.10,

$$g_1 \otimes \cdots \otimes g_m(\mathbf{x}_1 \wedge \cdots \wedge \mathbf{x}_m) = \det[a_{ij}].$$

28. Under the same conditions of the former fact,

$$g_1 \otimes \cdots \otimes g_m(\mathbf{x}_1 \vee \cdots \vee \mathbf{x}_m) = \operatorname{per}[a_{ij}].$$

29. Let $(f_1, \ldots, f_n)$ be the dual basis of the basis $(\mathbf{b}_1, \ldots, \mathbf{b}_n)$. Then, choosing $(\bigotimes^m V)^*$ as the model for $\bigotimes^m V^*$:

(a)

$$\left(f_\alpha^\otimes\right)_{\alpha \in \Gamma_{m,n}}$$

is the dual basis of the basis $(\mathbf{b}_\alpha^\otimes)_{\alpha \in \Gamma_{m,n}}$ of $\otimes^m V$.

(b)

$$\left((f_\alpha^\otimes)_{|\bigwedge^m V}\right)_{\alpha \in Q_{m,n}}$$

is the dual basis of the basis $(\mathbf{b}_\alpha^\wedge)_{\alpha \in Q_{m,n}}$ of $\bigwedge^m V$.

(c)

$$\left(\frac{1}{\lambda_\alpha!}(f_\alpha^\otimes)_{|\bigvee^m V}\right)_{\alpha \in G_{m,n}}$$

is the dual basis of the basis $(\mathbf{b}_\alpha^\vee)_{\alpha \in G_{m,n}}$ of $\bigvee^m V$.

Let $\mathbf{v}_1, \ldots, \mathbf{v}_m$ be vectors of V and $(\mathbf{b}_1, \ldots, \mathbf{b}_n)$ be a basis of V.

30. Let $A = [a_{ij}]$ be the $n \times m$ matrix over F such that $\mathbf{v}_j = \sum_{i=1}^n a_{ij} \mathbf{b}_i,\ j = 1, \ldots, m$. Then:

(a)

$$\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m = \sum_{\alpha \in \Gamma_{m,n}} \left(\prod_{t=1}^m a_{\alpha(t),t} \right) \mathbf{b}_\alpha^\otimes;$$

(b)

$$\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m = \sum_{\alpha \in Q_{m,n}} \det A[\alpha|\iota]\mathbf{b}_{\alpha}^{\wedge};$$

(c)

$$\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m = \sum_{\alpha \in G_{m,n}} \frac{1}{\lambda_\alpha!}\mathrm{per} A[\alpha|\iota]\mathbf{b}_{\alpha}^{\vee}.$$

31. $\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m = 0$ if and only if $(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ is linearly dependent.
32. $\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m = 0$ if and only if one of the $\mathbf{v}_i$s is equal to 0.
33. Let $\mathbf{u}_1, \ldots, \mathbf{u}_m$ be vectors of V.
    (a) If $(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ and $(\mathbf{u}_1, \ldots, \mathbf{u}_m)$ are linearly independent families of vectors of V, then

    $$\mathrm{Span}(\{\mathbf{u}_1 \wedge \cdots \wedge \mathbf{u}_m\}) = \mathrm{Span}(\{\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m\})$$

    if and only if

    $$\mathrm{Span}(\{\mathbf{u}_1, \ldots, \mathbf{u}_m\}) = \mathrm{Span}(\{\mathbf{v}_1, \ldots, \mathbf{v}_m\}).$$

    (b) If $(\mathbf{v}_1, \ldots, \mathbf{v}_m)$ and $(\mathbf{u}_1, \ldots, \mathbf{u}_m)$ are families of nonzero vectors of V, then

    $$\mathrm{Span}(\{\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m\}) = \mathrm{Span}(\{\mathbf{u}_1 \vee \cdots \vee \mathbf{u}_m\})$$

    if and only if there exists a permutation σ of S_m satisfying

    $$\mathrm{Span}(\{\mathbf{v}_i\}) = \mathrm{Span}(\{\mathbf{u}_{\sigma(i)}\}), \quad i = 1, \ldots, m.$$

Examples:

1. Consider as a model of $\bigotimes^2 F^n$, the vector space of the $n \times n$ matrices with the usual tensor multiplication. Then $\bigwedge^2 F^n$ is the subspace of the $n \times n$ antisymmetric matrices over F and $\bigvee^2 F^n$ is the subspace of the $n \times n$ symmetric matrices over F. Moreover, for $(a_1, \ldots, a_n), (b_1, \ldots, b_n) \in F^n$:
    (a) $(a_1, \ldots, a_n) \wedge (b_1, \ldots, b_n) = [a_i b_j - b_i a_j]_{i,j=1,\ldots,n}$.
    (b) $(a_1, \ldots, a_n) \vee (b_1, \ldots, b_n) = [a_i b_j + b_i a_j]_{i,j=1,\ldots,n}$.

    With these definitions, $\mathbf{e}_i \wedge \mathbf{e}_j = E_{ij} - E_{ji}$ and $\mathbf{e}_i \vee \mathbf{e}_j = E_{ij} + E_{ji}$, where $\mathbf{e}_i$, $\mathbf{e}_j$, and E_{ij} are standard basis vectors of F^m, F^n, and $F^{m \times n}$.
2. For $\mathbf{x} \in V$, $\mathbf{x} \vee \cdots \vee \mathbf{x} = m!\mathbf{x} \otimes \cdots \otimes \mathbf{x}$.

14.7 The Tensor Multiplication, the Alt Multiplication, and the Sym Multiplication

Next we will introduce "external multiplications" for tensor powers, Grassmann spaces, and symmetric spaces. Let p, q be positive integers.

Definitions:

The (p, q)-**tensor multiplication** is the unique bilinear map (recall Fact 14.6.20), $(\mathbf{z}, \mathbf{z}') \mapsto \mathbf{z} \otimes \mathbf{z}'$ from $(\bigotimes^p V) \times (\bigotimes^q V)$ into $\bigotimes^{p+q} V$, satisfying

$$(\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_p) \otimes (\mathbf{v}_{p+1} \otimes \cdots \otimes \mathbf{v}_{p+q}) = \mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_{p+q}.$$

The (p, q)**-alt multiplication** (briefly alt multiplication) is the unique bilinear map (recall Fact 14.6.21), $(z, z') \mapsto z \wedge z'$ from $(\bigwedge^p V) \times (\bigwedge^q V)$ into $\bigwedge^{p+q} V$, satisfying

$$(\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_p) \wedge (\mathbf{v}_{p+1} \wedge \cdots \wedge \mathbf{v}_{p+q}) = \mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_{p+q}.$$

The (p, q)**-sym multiplication** (briefly sym multiplication) is the unique bilinear map (recall Fact 14.6.22), $(z, z') \mapsto z \vee z'$ from $(\bigvee^p V) \times (\bigvee^q V)$ into $\bigvee^{p+q} V$, satisfying

$$(\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_p) \vee (\mathbf{v}_{p+1} \vee \cdots \vee \mathbf{v}_{p+q}) = \mathbf{v}_1 \vee \cdots \vee \mathbf{v}_{p+q}.$$

These definitions can be extended to include the cases where either p or q is zero, taking as multiplication the scalar product.

Let m, n be positive integers satisfying $1 \leq m < n$. Let $\alpha \in Q_{m,n}$. We denote by α^c the element of $Q_{n-m,n}$ whose range is the complement in $\{1, \ldots, n\}$ of the range of α and by $\widetilde{\alpha}$ the permutation of S_n:

$$\widetilde{\alpha} = \begin{pmatrix} 1 & \cdots & m & m+1 & \cdots & n \\ \alpha(1) & \cdots & \alpha(m) & \alpha^c(1) & \cdots & \alpha^c(n-m) \end{pmatrix}.$$

Facts:

The following facts can be found in [Mar73, Chap. 2], [Mer97, Chap. 5], and [Spi79, Chap. 7].

1. The product by the alt multiplication of arbitrary elements $z \in \bigwedge^p V$ and $z' \in \bigwedge^q V$ is given by
$$z \wedge z' = \frac{(p+q)!}{p!q!} \operatorname{Alt}_{p+q}(z \otimes z').$$
2. The product of $z \in \bigvee^p V$ and $z' \in \bigvee^q V$ by the sym-multiplication is given by
$$z \vee z' = \frac{(p+q)!}{p!q!} \operatorname{Sym}_{p+q}(z \otimes z').$$
3. The alt-product $z \wedge z'$ and the sym product $z \vee z'$ are not, in general, decomposable elements of any Grassmann or symmetric space of degree 2.
4. Let $0 \neq z \in \bigwedge^m V$. Then z is decomposable if and only if there exists a linearly independent family of vectors $\mathbf{v}_1, \ldots, \mathbf{v}_m$ satisfying $z \wedge \mathbf{v}_i = 0, i = 1, \ldots, m$.
5. If $\dim(V) = n \geq 2$, all elements of $\bigwedge^{n-1} V$ are decomposable.
6. The multiplications defined in this subsection are associative. Therefore,
$$\begin{aligned} &z \otimes z' \otimes z'', z \in \bigotimes^p V, \quad z' \in \bigotimes^q V, \quad z'' \in \bigotimes^r V; \\ &w \wedge w' \wedge w'', w \in \bigwedge^p V, \quad w' \in \bigwedge^q V, \quad w'' \in \bigwedge^r V; \\ &y \vee y' \vee y'', y \in \bigvee^p V, \quad y' \in \bigvee^q V, \quad y'' \in \bigvee^r V \end{aligned}$$
are meaningful as well as similar expressions with more than three factors.
7. If $w \in \bigwedge^p V$, $w' \in \bigwedge^q V$, then
$$w' \wedge w = (-1)^{pq} w \wedge w'.$$
8. If $y \in \bigvee^p V$, $y' \in \bigvee^q V$, then
$$y' \vee y = y \vee y'.$$

Examples:

1. When the vector space is the dual $V^* = L(V;F)$ of a vector space and we choose as the models of tensor powers of V^* the spaces of multilinear forms (with the usual tensor multiplication), then the image of the tensor multiplication $\varphi \otimes \psi$ ($\varphi \in L^p(V;F)$ and $\psi \in L^q(V;F)$) on $(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q})$ is given by the equality
$$(\varphi \otimes \psi)(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q}) = \varphi(\mathbf{v}_1, \ldots, \mathbf{v}_p)\psi(\mathbf{v}_{p+1}, \ldots, \mathbf{v}_{p+q}).$$

2. When the vector space is the dual $V^* = L(V;F)$ of a vector space and we choose as the models for the tensor powers of V^* the spaces of multilinear forms (with the usual tensor multiplication), the alt multiplication of $\varphi \in A^p(V;F)$ and $\psi \in A^q(V;F)$ takes the form
$$\begin{aligned}&(\varphi \wedge \psi)(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q})\\ &\quad= \frac{1}{p!q!} \sum_{\sigma \in S_{p+q}} \operatorname{sgn}(\sigma)\varphi(\mathbf{v}_{\sigma(1)}, \ldots, \mathbf{v}_{\sigma(p)})\psi(\mathbf{v}_{\sigma(p+1)}, \ldots, \mathbf{v}_{\sigma(p+q)}).\end{aligned}$$

3. The equality in Example 2 has an alternative expression that can be seen as a "Laplace expansion" for antisymmetric forms
$$\begin{aligned}&(\varphi \wedge \psi)(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q})\\ &\quad= \sum_{\alpha \in Q_{p,p+q}} \operatorname{sgn}(\widetilde{\alpha})\varphi(\mathbf{v}_{\alpha(1)}, \ldots, \mathbf{v}_{\alpha(p)})\psi(\mathbf{v}_{\alpha^c(1)}, \ldots, \mathbf{v}_{\alpha^c(q)}).\end{aligned}$$

4. In the case $p = 1$, the equality in Example 3 has the form
$$\begin{aligned}&(\varphi \wedge \psi)(\mathbf{v}_1, \ldots, \mathbf{v}_{q+1})\\ &\quad= \sum_{j=1}^{q+1} (-1)^{j+1}\varphi(\mathbf{v}_j)\psi(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}, \mathbf{v}_{j+1}, \ldots, \mathbf{v}_{q+1}).\end{aligned}$$

5. When the vector space is the dual $V^* = L(V;F)$ of a vector space and we choose as the models of tensor powers of V^* the spaces of multilinear forms (with the usual tensor multiplication), the value of sym multiplication of $\varphi \in S^p(V;F)$ and $\psi \in S^q(V;F)$ on $(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q})$ is
$$\begin{aligned}&(\varphi \vee \psi)(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q})\\ &\quad= \frac{1}{p!q!} \sum_{\sigma \in S_{p+q}} \varphi(\mathbf{v}_{\sigma(1)}, \ldots, \mathbf{v}_{\sigma(p)})\psi(\mathbf{v}_{\sigma(p+1)}, \ldots, \mathbf{v}_{\sigma(p+q)}).\end{aligned}$$

6. The equality in Example 5 has an alternative expression that can be seen as a "Laplace expansion" for symmetric forms
$$\begin{aligned}&(\varphi \vee \psi)(\mathbf{v}_1, \ldots, \mathbf{v}_{p+q})\\ &\quad= \sum_{\alpha \in Q_{p,p+q}} \varphi(\mathbf{v}_{\alpha(1)}, \ldots, \mathbf{v}_{\alpha(p)})\psi(\mathbf{v}_{\alpha^c(1)}, \ldots, \mathbf{v}_{\alpha^c(q)}).\end{aligned}$$

7. In the case $p = 1$, the equality in Example 6 has the form

$$\begin{aligned}(\varphi \vee \psi)(\mathbf{v}_1, \ldots, \mathbf{v}_{q+1}) \\ = \sum_{j=1}^{q+1} \varphi(\mathbf{v}_j)\psi(\mathbf{v}_1, \ldots, \mathbf{v}_{j-1}, \mathbf{v}_{j+1}, \ldots, \mathbf{v}_{q+1}).\end{aligned}$$

14.8 Associated Maps

Definitions:

Let $\theta \in L(V; U)$. The linear map $\theta \otimes \cdots \otimes \theta$ from $\bigotimes^m V$ into $\bigotimes^m U$ (the tensor product of m copies of θ) will be denoted by $\bigotimes^m \theta$. The subspaces $\bigwedge^m V$ and $\bigvee^m V$ are mapped by $\bigotimes^m \theta$ into $\bigwedge^m U$ and $\bigvee^m U$, respectively. The restriction of $\bigotimes^m \theta$ to $\bigwedge^m V$ and to $\bigvee^m V$ will be denoted, $\bigwedge^m \theta$ and $\bigvee^m \theta$, respectively.

Facts:

The following facts can be found in [Mar73, Chap. 2].

1. Let $\mathbf{v}_1, \ldots, \mathbf{v}_m \in V$. The following properties hold:
   (a) $\bigwedge^m \theta(\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m) = \theta(\mathbf{v}_1) \wedge \cdots \wedge \theta(\mathbf{v}_m)$.
   (b) $\bigvee^m \theta(\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m) = \theta(\mathbf{v}_1) \vee \cdots \vee \theta(\mathbf{v}_m)$.
2. Let $\theta \in L(V; U)$ and $\eta \in L(W, V)$. The following equalities hold:
   (a) $\bigwedge^m(\theta\eta) = \bigwedge^m(\theta) \bigwedge^m(\eta)$.
   (b) $\bigvee^m(\theta\eta) = \bigvee^m(\theta) \bigvee^m(\eta)$.
3. $\bigwedge^m(I_V) = I_{\bigwedge^m V}$; $\bigvee^m(I_V) = I_{\bigvee^m V}$.
4. Let $\theta, \eta \in L(V; U)$ and assume that rank $(\theta) > m$. Then

   $$\bigwedge^m \theta = \bigwedge^m \eta$$

   if and only if $\theta = a\eta$ and $a^m = 1$.
5. Let $\theta, \eta \in L(V; U)$. Then $\bigvee^m \theta = \bigvee^m \eta$ if and only if $\theta = a\eta$ and $a^m = 1$.
6. If θ is one-to-one (respectively onto), then $\bigwedge^m \theta$ and $\bigvee^m \theta$ are one-to-one (respectively onto).

   From now on θ is a linear operator on the n-dimensional vector space V.
7. Considering $\bigwedge^n \theta$ as an operator in the one-dimensional space $\bigwedge^n V$,

   $$\left(\bigwedge^n \theta\right)(\mathbf{z}) = \det(\theta)\mathbf{z}, \text{ for all } \mathbf{z} \in \bigwedge^n V.$$

8. If the characteristic polynomial of θ is

   $$\mathbf{p}_\theta(x) = x^n + \sum_{i=1}^{n} (-1)^i a_i x^{n-i},$$

   then

   $$a_i = \operatorname{tr}\left(\bigwedge^i \theta\right), \quad i = 1, \ldots, n.$$

9. If θ has spectrum $\sigma(\theta) = \{\lambda_1, \ldots, \lambda_n\}$, then

$$\sigma\Big(\bigwedge^m \theta\Big) = \left\{\prod_{i=1}^{m} \lambda_{\alpha(i)}\right\}_{\alpha \in Q_{m,n}}, \quad \sigma\Big(\bigvee^m \theta\Big) = \left\{\prod_{i=1}^{m} \lambda_{\alpha(i)}\right\}_{\alpha \in G_{m,n}}.$$

10.

$$\det\left(\bigwedge^m \theta\right) = \det(\theta)^{\binom{n-1}{m-1}}, \qquad \det\left(\bigvee^m \theta\right) = \det(\theta)^{\binom{m+n-1}{m-1}}.$$

14.9 Tensor Algebras

Definitions:

Let A be an F-algebra and $(A_k)_{k\in\mathbb{N}}$ a family of vector subspaces of A. The algebra A is **graded** by $(A_k)_{k\in\mathbb{N}}$ if the following conditions are satisfied:

(a) $A = \bigoplus_{k\in\mathbb{N}} A_k$.
(b) $A_i A_j \subseteq A_{i+j}$ for every $i, j \in \mathbb{N}$.

The elements of A_k are known as **homogeneous of degree** k, and the elements of $\bigcup_{n\in\mathbb{N}} A_k$ are called **homogeneous**.

By condition (a), every element of A can be written uniquely as a sum of (a finite number of nonzero) homogeneous elements, i.e., given $\mathbf{u} \in A$ there exist uniquely determined $\mathbf{u}_k \in A_k, k \in \mathbb{N}$ satisfying

$$\mathbf{u} = \sum_{k\in\mathbb{N}} \mathbf{u}_k.$$

These elements are called **homogeneous components of u**. The summand of degree k in the right-hand side of the former equality is denoted by $[\mathbf{u}]_k$.

From now on V is a finite dimensional vector space over F of dimension n. As before $\bigotimes^k V$ denotes the kth-tensor power of V.

Denote by $\bigotimes V$ the external direct sum of the vector spaces $\bigotimes^k V,\ k \in \mathbb{N}$. If $\mathbf{z}_i \in \bigotimes^i V$, $\mathbf{z}_i$ is identified with the sequence $z \in \bigotimes V$ whose ith coordinate is $\mathbf{z}_i$ and the remaining coordinates are 0. Therefore, after this identification,

$$\bigotimes V = \bigoplus_{k\in\mathbb{N}} \bigotimes^k V.$$

Consider in $\bigotimes V$ the multiplication $(\mathbf{x}, \mathbf{y}) \mapsto \mathbf{x} \otimes \mathbf{y}$ defined for $\mathbf{x}, \mathbf{y} \in \bigotimes V$ by

$$[x \otimes y]_k = \sum_{\substack{r,s\in\mathbb{N} \\ r+s=k}} [x]_r \otimes [y]_s, \quad k \in \mathbb{N},$$

where $[x]_r \otimes [y]_s$ is the (r, s)-tensor multiplication of $[x]_r$ and $[y]_s$ introduced in the definitions of Section 14.7. The vector space $\bigotimes V$ equipped with this multiplication is called the **tensor algebra** on V.

Denote by $\bigwedge V$ the external direct sum of the vector spaces $\bigwedge^k V,\ k \in \mathbb{N}$. If $z_i \in \bigwedge^i V$, z_i is identified with the sequence $z \in \bigwedge V$ whose ith coordinate is z_i and the remaining coordinates are 0. Therefore, after this identification,

$$\bigwedge V = \bigoplus_{k\in\mathbb{N}} \bigwedge^k V.$$

Recall that $\bigwedge^k V = \{0\}$ if $k > n$. Then

$$\bigwedge V = \bigoplus_{k=0}^{n} \bigwedge^k V$$

and the elements of $\bigwedge V$ can be uniquely written in the form

$$z_0 + z_1 + \cdots + z_n, \quad z_i \in \bigwedge^i V, \quad i = 0, \dots, n.$$

Consider in $\bigwedge V$ the multiplication $(x, y) \mapsto x \wedge y$ defined, for $x, y \in \bigwedge V$, by

$$[x \wedge y]_k = \sum_{\substack{r,s \in \{0,\, \dots, n\} \\ r+s=k}} [x]_r \wedge [y]_s, \quad k \in \{0,\, \dots, n\},$$

where $[x]_r \wedge [y]_s$ is the (r, s)-alt multiplication of $[x]_r$ and $[y]_s$ referred to in definitions of Section 14.7. The vector space $\bigwedge V$ equipped with this multiplication is called the **Grassmann algebra** on V.

Denote by $\bigvee V$ the external direct sum of the vector spaces $\bigvee^k V,\ k \in \mathbb{N}$.

If $z_i \in \bigvee^i V$, we identify z_i with the sequence $z \in \bigvee V$ whose ith coordinate is z_i and the remaining coordinates are 0. Therefore, after this identification

$$\bigvee V = \bigoplus_{k \in \mathbb{N}} \bigvee^k V.$$

Consider in $\bigvee V$ the multiplication $(x, y) \mapsto x \vee y$ defined for $x, y \in \bigvee V$ by

$$[x \vee y]_k = \sum_{\substack{r,s \in \mathbb{N} \\ r+s=k}} [x]_r \vee [y]_s, \quad k \in \mathbb{N},$$

where $[x]_r \vee [y]_s$ is the (r, s)-sym multiplication of $[x]_r$ and $[y]_s$ referred to in definitions of Section 14.7.

The vector space $\bigvee V$ equipped with this multiplication is called the **symmetric algebra** on V.

Facts:

The following facts can be found in [Mar73, Chap. 3] and [Gre67, Chaps. II and III].

1. The vector space $\bigotimes V$ with the multiplication $(x, y) \mapsto x \otimes y$ is an algebra over F graded by $(\bigotimes^k V)_{k \in \mathbb{N}}$, whose identity is the identity of $F = \bigotimes^0 V$.
2. The vector space $\bigwedge V$ with the multiplication $(x, y) \mapsto x \wedge y$ is an algebra over F graded by $(\bigwedge^k V)_{k \in \mathbb{N}}$ whose identity is the identity of $F = \bigwedge^0 V$.
3. The vector space $\bigvee V$ with the multiplication $(x, y) \mapsto x \vee y$ is an algebra over F graded by $(\bigvee^k V)_{k \in \mathbb{N}}$ whose identity is the identity of $F = \bigvee^0 V$.
4. The F-algebra $\bigotimes V$ does not have zero divisors.
5. Let B be an $F-$algebra and θ a linear map from V into B. Then there exists a unique algebra-homomorphism h from $\bigotimes V$ into B satisfying $h|V = \theta$.
6. Let B be an F-algebra and θ a linear map from V into B satisfying $\theta(\mathbf{x})\theta(\mathbf{y}) = -\theta(\mathbf{y})\theta(\mathbf{x})$ for all $\mathbf{x}, \mathbf{y} \in V$. Then there exists a unique algebra homomorphism h from $\bigwedge V$ into B satisfying $h|V = \theta$.
7. Let B be an F-algebra and θ a linear map from V into B satisfying $\theta(\mathbf{x})\theta(\mathbf{y}) = \theta(\mathbf{y})\theta(\mathbf{x})$, for all $\mathbf{x}, \mathbf{y} \in V$. Then there exists a unique algebra homomorphism h from $\bigvee V$ into B satisfying $h|V = \theta$.

8. Let $(\mathbf{b}_1, \ldots, \mathbf{b}_n)$ be a basis of V. The symmetric algebra $\bigvee^m V$ is isomorphic to the algebra of polynomials in n indeterminates, $F[x_1, \ldots, x_n]$, by the algebra isomorphism whose restriction to V is the linear map that maps $\mathbf{b}_i$ into x_i, $i = 1, \ldots, n$.

Examples:

1. Let $x_1, \ldots, x_n$ be n distinct indeterminates. Let V be the vector space of the formal linear combinations with coefficients in F in the indeterminates $x_1, \ldots, x_n$. The tensor algebra on V is the algebra of the polynomials in the noncommuting indeterminates $x_1, \ldots, x_n$ ([Coh03], [Jac64]). This algebra is denoted by
$$F\langle x_1, \ldots, x_n\rangle.$$
The elements of this algebra are of the form
$$f(x_1, \ldots, x_n) = \sum_{m \in \mathbb{N}} \sum_{\alpha \in \Gamma_{m,n}} c_\alpha x_{\alpha(1)} \otimes \cdots \otimes x_{\alpha(m)},$$
with all but a finite number of the coefficients c_α equal to zero.

14.10 Tensor Product of Inner Product Spaces

Unless otherwise stated, within this section V, U, and W, as well as these letters with subscripts, superscripts, or accents, are finite dimensional vector spaces over $\mathbb{R}$ or over $\mathbb{C}$, equipped with an inner product.

The inner product of V is denoted by $\langle\ ,\ \rangle_V$. When there is no risk of confusion $\langle\ ,\ \rangle$ is used instead. In this section, F means either the field $\mathbb{R}$ or the field $\mathbb{C}$.

Definitions:

Let θ be a linear map from V into W. In this section, the notation θ^* and the name "adjoint" will be used for the linear map from W into V satisfying $\langle \theta(\mathbf{x}), \mathbf{y}\rangle = \langle \mathbf{x}, \theta^*(\mathbf{y})\rangle$ for all $\mathbf{x} \in V$ and $\mathbf{y} \in W$ (instead of the dual map from the dual W^* of W into the dual V^* of V).

The unique inner product $\langle\ ,\ \rangle$ on $V_1 \otimes \cdots \otimes V_m$ satisfying, for every $\mathbf{v}_i, \mathbf{u}_i \in V_i$, $i = 1, \ldots, m$,
$$\langle \mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m, \mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_m\rangle = \prod_{i=1}^{m} \langle \mathbf{v}_i, \mathbf{u}_i\rangle_{V_i},$$
is called **induced inner product** associated with the inner products $\langle\ ,\ \rangle_{V_i}$, $i = 1, \ldots, m$.

Let U, V be inner product spaces over F. We consider defined in $L(V; U)$ the **Hilbert–Schmidt** inner product, i.e., the inner product defined, for $\theta, \eta \in L(V; U)$, by $\langle \theta, \eta\rangle = \operatorname{tr}(\eta^*\theta)$.

The Hilbert-Schmidt inner product in the field F (recall that $F = \mathbb{R}$ or $F = \mathbb{C}$) $(a, b) \mapsto \langle a, b\rangle = a\bar{b}$ is called the **canonical** inner product in F and it is the one assumed to equip F from now on.

Let V be an inner product space with the inner product $\langle\ .\ \rangle_V$. Then V^* becomes an inner product space by equipping it with the Hilbert-Schmidt inner product. This inner product in V^* is called the **dual** inner product of $\langle\ .\ \rangle_V$.

For each $\mathbf{v} \in V$, let $f_{\mathbf{v}} \in V^*$ be defined by $f_{\mathbf{v}}(\mathbf{u}) = \langle \mathbf{u}, \mathbf{v}\rangle$.

From now on $V_1 \otimes \cdots \otimes V_m$ is assumed to be equipped with the inner product induced by the inner products $\langle\ ,\ \rangle_{V_i}$, $i = 1, \ldots, m$.

Facts:

The following facts can be found in [Mar73, Chap. 2].

1. The map $\mathbf{v} \to f_{\mathbf{v}}$ is bijective-linear if $F = \mathbb{R}$ and conjugate-linear (i.e., $c\mathbf{v} \mapsto \bar{c}f_{\mathbf{v}}$) if $F = \mathbb{C}$.
2. For $\mathbf{v}, \mathbf{v}'$ in V, $\langle \mathbf{v}, \mathbf{v}' \rangle = \langle f_{\mathbf{v}'}, f_{\mathbf{v}} \rangle$.
3. If $(\mathbf{b}_{i1}, \ldots, \mathbf{b}_{in_i})$ is an orthonormal basis of V_i, $i = 1, \ldots, m$, then $\{\mathbf{b}^{\otimes}_{\alpha} : \alpha \in \Gamma(n_1, \ldots, n_m)\}$ is an orthonormal basis of $V_1 \otimes \cdots \otimes V_m$.
4. Let $\theta_i \in L(V_i; W_i)$, $i = 1, \ldots, m$, with adjoint map $\theta_i^* \in L(W_i, V_i)$. Then,
$$(\theta_1 \otimes \cdots \otimes \theta_m)^* = \theta_1^* \otimes \cdots \otimes \theta_m^*.$$
5. If $\theta_i \in L(V_i; V_i)$ is Hermitian (normal, unitary), $i = 1, \ldots, m$, then $\theta_1 \otimes \cdots \otimes \theta_m$ is also Hermitian (normal, unitary).
6. Let $\theta \in L(V; V)$. If θ is Hermitian (normal, unitary) then $\bigotimes^m \theta$, $\bigwedge^m \theta$ and $\bigvee^m \theta$, are normal.
7. Let $\theta \in L(V; V)$. If $\bigotimes^m \theta$ ($\bigvee^m \theta$) is normal, then θ is normal.
8. Let $\theta \in L(V; V)$. Assume that θ is a linear operator on V with rank greater than m. If $\bigwedge^m \theta$ is normal, then θ is normal.
9. If $\mathbf{u}_1, \ldots, \mathbf{u}_m, \mathbf{v}_1, \ldots, \mathbf{v}_m \in V$:
$$\langle \mathbf{u}_1 \wedge \cdots \wedge \mathbf{u}_m, \mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m \rangle = m! \det\langle \mathbf{u}_i, \mathbf{v}_j \rangle,$$
$$\langle \mathbf{u}_1 \vee \cdots \vee \mathbf{u}_m, \mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m \rangle = m! \mathrm{per}\langle \mathbf{u}_i, \mathbf{v}_j \rangle.$$
10. Let $(\mathbf{b}_1, \ldots, \mathbf{b}_n)$ be an orthonormal basis of V. Then the basis $(\mathbf{b}^{\otimes}_{\alpha})_{\alpha \in \Gamma_{m,n}}$ is an orthonormal basis of $\bigotimes^m V$, $(\sqrt{\frac{1}{m!}}\mathbf{b}^{\wedge}_{\alpha})_{\alpha \in Q_{m,n}}$ is an orthonormal basis of $\bigwedge^m V$, and $(\sqrt{\frac{1}{m!\lambda_\alpha!}}\mathbf{b}^{\vee}_{\alpha})_{\alpha \in G_{m,n}}$ is an orthonormal basis of $\bigvee^m V$.

Examples:

1. When we choose F as the mth tensor power of F with the field multiplication as the tensor multiplication, then the canonical inner product is the inner product induced in $\bigotimes^m F$ by the canonical inner product.
2. When we assume V as the tensor product of F and V with the tensor multiplication $a \otimes \mathbf{v} = a\mathbf{v}$, the inner product induced by the canonical inner product of F and the inner product of V is the inner product of V.
3. Consider $L(V; U)$ as the tensor product of U and V^* by the tensor multiplication $(\mathbf{u} \otimes f)(\mathbf{v}) = f(\mathbf{v})\mathbf{u}$. Assume in V^* the inner product dual of the inner product of V. Then, if $(\mathbf{v}_1, \ldots, \mathbf{v}_n)$ is an orthonormal basis of V and $\theta, \eta \in L(V; U)$, we have
$$\langle \theta, \eta \rangle = \sum_{j=1}^{m} \langle \theta(\mathbf{v}_j), \eta(\mathbf{v}_j) \rangle = \mathrm{tr}(\eta^* \theta),$$
i.e., the associated inner product of $L(V; U)$ is the Hilbert–Schmidt one.
4. Consider $F^{m \times n}$ as the tensor product of F^m and F^n by the tensor multiplication described in Example 14.2.1. Then if we consider in F^m and F^n the usual inner product we get in $F^{m \times n}$ as the induced inner product, the inner product
$$(A, B) \mapsto \mathrm{tr}(\overline{B}^T A) = \sum_{i,j} a_{ij} \overline{b_{i,j}}.$$
5. Assume that in V_i^* is defined the inner product dual of $\langle\ ,\ \rangle_{V_i}$, $i = 1, \ldots, m$. Then choosing $L(V_1, \ldots, V_m; F)$ as the tensor product of $V_1^*, \ldots, V_m^*$, with the usual tensor multiplication, the inner product of $L(V_1, \ldots, V_m; F)$ induced by the duals of inner products on V_i^*, $i = 1, \ldots, m$ is given by the equalities

$$\langle \varphi, \psi \rangle = \sum_{\alpha \in \Gamma} \varphi(\mathbf{b}_{1,\alpha(1)}, \dots, \mathbf{b}_{m,\alpha(m)}) \overline{\psi(\mathbf{b}_{1,\alpha(1)}, \dots, \mathbf{b}_{m,\alpha(m)})}.$$

14.11 Orientation and Hodge Star Operator

In this section, we assume that all vector spaces are real finite dimensional inner product spaces.

Definitions:

Let V be a one-dimensional vector space. The equivalence classes of the equivalence relation $\sim$, defined by the condition $\mathbf{v} \sim \mathbf{v}'$ if there exists a positive real number $a > 0$ such that $\mathbf{v}' = a\mathbf{v}$, partitions the set of nonzero vectors of V into two subsets.

Each one of these subsets is known as an open **half-line**.

An **orientation** of V is a choice of one of these subsets. The fixed open half-line is called the **positive half-line** and its vectors are known as **positive**. The other open half-line of V is called **negative half-line**, and its vectors are called **negative**.

The field $\mathbb{R}$, regarded as one-dimensional vector space, has a "natural" orientation that corresponds to choose as positive half-line the set of positive numbers.

If V is an n-dimensional vector space, $\bigwedge^n V$ is a one-dimensional vector space (recall Fact 14.6.23). An **orientation of** V is an orientation of $\bigwedge^n V$.

A basis $(\mathbf{b}_1, \dots, \mathbf{b}_n)$ of V is said to be **positively oriented** if $\mathbf{b}_1 \wedge \cdots \wedge \mathbf{b}_n$ is positive and **negatively oriented** if $\mathbf{b}_1 \wedge \cdots \wedge \mathbf{b}_n$ is negative.

Throughout this section, $\bigwedge^m V$ will be equipped with the inner product $\langle \ , \ \rangle_\wedge$, a positive multiple of the induced inner product, defined by

$$\langle z, w \rangle_\wedge = \frac{1}{m!} \langle z, w \rangle,$$

where the inner product on the right-hand side of the former equality is the inner product of $\bigotimes^m V$ induced by the inner product of V. This is also the inner product that is considered whenever the norm of antisymmetric tensors is referred.

The positive tensor of norm 1 of $\bigwedge^n V$, $\mathfrak{u}_V$, is called **fundamental tensor of** V or **element of volume** of V.

Let V be a real oriented inner product space. Let $0 \leq m \leq n$.

The **Hodge star operator** is the linear operator $\bigstar_m$ (denoted also by $\bigstar$) from $\bigwedge^m V$ into $\bigwedge^{n-m} V$ defined by the following condition:

$$\langle \bigstar_m(w), w' \rangle_\wedge \mathfrak{u}_V = w \wedge w', \text{ for all } w' \in \bigwedge^{n-m} V.$$

Let $n \geq 1$ and let V be an n-dimensional oriented inner product space over $\mathbb{R}$. The **external product on** V is the map

$$(\mathbf{v}_1, \dots, \mathbf{v}_{n-1}) \mapsto \mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1} = \bigstar_{n-1}(\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_{n-1}),$$

from V^{n-1} into V.

Facts:

The following facts can be found in [Mar75, Chap. 1] and [Sch75, Chap. 1].

1. If $(\mathbf{b}_1, \dots, \mathbf{b}_n)$ is a positively oriented orthonormal basis of V, then $\mathfrak{u}_V = \mathbf{b}_1 \wedge \cdots \wedge \mathbf{b}_n$.

2. If $(\mathbf{b}_1, \ldots, \mathbf{b}_n)$ is a positively oriented orthonormal basis of V, then
$$\bigstar_m \mathbf{b}^{\wedge}_{\alpha} = \operatorname{sgn}(\widetilde{\alpha})\mathbf{b}^{\wedge}_{\alpha^c}, \quad \alpha \in Q_{m,n},$$
where $\widetilde{\alpha}$ and α^c are defined in Section 14.7.
3. Let $(\mathbf{v}_1, \ldots, \mathbf{v}_n)$ and $(\mathbf{u}_1, \ldots, \mathbf{u}_n)$ be two bases of V and $\mathbf{v}_j = \sum a_{ij}\mathbf{u}_i$, $j = 1, \ldots, n$. Let $A = [a_{ij}]$. Since (recall Fact 14.6.30)
$$\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_n = \det(A)\mathbf{u}_1 \wedge \cdots \wedge \mathbf{u}_n,$$
two bases have the same orientation if and only if their transition matrix has a positive determinant.
4. $\bigstar$ is an isometric isomorphism.
5. $\bigstar_0$ is the linear isomorphism that maps $1 \in \mathbb{R}$ onto the fundamental tensor.
6. $\bigstar_m \bigstar_{n-m} = (-1)^{m(n-m)} I_{\bigwedge^{n-m} V}$.

Let V be an n-dimensional oriented inner product space over $\mathbb{R}$.

7. If $m \neq 0$ and $m \neq n$, the Hodge star operator maps the set of decomposable elements of $\bigwedge^m V$ onto the set of decomposable elements of $\bigwedge^{n-m} V$.
8. Let $(\mathbf{x}_1, \ldots, \mathbf{x}_m)$ be a linearly independent family of vectors of V. Then
$$\mathbf{y}_1 \wedge \cdots \wedge \mathbf{y}_{n-m} = \bigstar_m(\mathbf{x}_1 \wedge \cdots \wedge \mathbf{x}_m)$$
if and only if the following three conditions hold:
   (a) $\mathbf{y}_1, \ldots, \mathbf{y}_{n-m} \in \operatorname{Span}(\{\mathbf{x}_1, \ldots, \mathbf{x}_m\})^{\perp}$;
   (b) $\|\mathbf{y}_1 \wedge \cdots \wedge \mathbf{y}_{n-m}\| = \|\mathbf{x}_1 \wedge \cdots \wedge \mathbf{x}_m\|$;
   (c) $(\mathbf{x}_1, \ldots, \mathbf{x}_m, \mathbf{y}_1, \ldots, \mathbf{y}_{n-m})$ is a positively oriented basis of V.
9. If $(\mathbf{v}_1, \ldots, \mathbf{v}_{n-1})$ is linearly independent, $\mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1}$ is completely characterized by the following three conditions:
   (a) $\mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1} \in \operatorname{Span}(\{\mathbf{v}_1, \ldots, \mathbf{v}_{n-1}\})^{\perp}$.
   (b) $\|\mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1}\| = \|\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_{n-1}\|$.
   (c) $(\mathbf{v}_1, \ldots, \mathbf{v}_{n-1}, \mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1})$ is a positively oriented basis of V.
10. Assume $V^* = L(V; F)$, with $\dim(V) \geq 1$, is equipped with the dual inner product. Consider $L^m(V; F)$ as a model for the mth tensor power of V^* with the usual tensor multiplication. Then $\bigwedge^m V^* = A^m(V; F)$. If λ is an antisymmetric form in $A^m(V; F)$, then $\bigstar_m(\lambda)$ is the form whose value in $(\mathbf{v}_1, \ldots, \mathbf{v}_{n-m})$ is the component in the fundamental tensor of $\lambda \wedge f_{v_1} \wedge \cdots \wedge f_{v_{n-m}}$,
$$\bigstar_m(\lambda)(\mathbf{v}_1, \ldots, \mathbf{v}_{n-m})\mathfrak{u}_{V^*} = \lambda \wedge f_{v_1} \wedge \cdots \wedge f_{v_{n-m}}.$$
11. Assuming the above setting for the Hodge star operator, the external product of $\mathbf{v}_1, \ldots, \mathbf{v}_{n-1}$ is the vector of V whose associated form is $(\mathfrak{u}_{V^*})_{\mathbf{v}_1,\ldots,\mathbf{v}_{n-1}}$ (recall that $(\mathfrak{u}_{V^*})_{\mathbf{v}_1,\ldots,\mathbf{v}_{n-1}}(\mathbf{v}_n) = \mathfrak{u}_{V^*}(\mathbf{v}_1, \ldots, \mathbf{v}_{n-1}, \mathbf{v}_n)$), i.e.,
$$f_{\mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1}} = (\mathfrak{u}_{V^*})_{\mathbf{v}_1,\ldots,\mathbf{v}_{n-1}}.$$
The preceeding formula can be unfolded by stating that for each $v \in V$, $\langle \mathbf{v}, \mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1}\rangle = \mathfrak{u}_{V^*}(\mathbf{v}_1, \ldots, \mathbf{v}_{n-1}, \mathbf{v})$.

Examples:

1. If V has dimension 0, the isomorphism $\bigstar_0$ from $\bigwedge^0 V = \mathbb{R}$ into $\bigwedge^0 V = \mathbb{R}$ is either the identity (in the case we choose the natural orientation of V) or $-I$ (in the case we fix the nonnatural orientation of V).
2. When V has dimension 2, the isomorphism $\bigstar_1$ is usually denoted by J. It has the property $J^2 = -I$ and corresponds to the positively oriented rotation of $\pi/2$.
3. Assume that V has dimension 2. Then the external product is the isomorphism J.
4. If $\dim(V) = 3$, the external product is the well-known cross product.

Lek-Heng Lim
University of Chicago

Most chapters in this handbook are concerned with various aspects and implications of linearity; Chapter 14 and this chapter are unusual in that they are about multilinearity. Just as linear operators and their coordinate representations, i.e., matrices, are the main objects of interest in other chapters, tensors and their coordinate representations, i.e., hypermatrices, are the main objects of interest in this chapter. The parallel is summarized in the following schematic:

$$\textit{linearity} \quad \to \quad \textit{linear operators, bilinear forms, dyads} \quad \to \quad \textit{matrices}$$
$$\textit{multilinearity} \quad \to \quad \textit{tensors} \quad \to \quad \textit{hypermatrices}$$

Chapter 14, or indeed the monographs on multilinear algebra such as [Gre78, Mar23, Nor84, Yok92], are about properties of a whole space of tensors. This chapter is about properties of a *single* tensor and its coordinate representation, a hypermatrix.

The first two sections introduce (1) a hypermatrix, (2) a tensor as an element of a tensor product of vector spaces, its coordinate representation as a hypermatrix, and a tensor as a multilinear functional. The next sections discuss the various generalizations of well-known linear algebraic and matrix theoretic notions, such as rank, norm, and determinant, to tensors and hypermatrices. The realization that these notions may be defined for order-d hypermatrices where $d > 2$ and that there are reasonably complete theories which parallel and generalize those for usual 2-dimensional matrices is a recent one. However, some of these hypermatrix notions have roots that go back as early as those for matrices. For example, the determinant of a $2 \times 2 \times 2$ hypermatrix can be found in Cayley's 1845 article [Cay45]; in fact, he studied 2-dimensional matrices and d-dimensional ones on an equal footing. The final section describes material that is omitted from this chapter for reasons of space.

In modern mathematics, there is a decided preference for coordinate-free, basis-independent ways of defining objects but we will argue here that this need not be the best strategy. The view of tensors as hypermatrices, while strictly speaking incorrect, is nonetheless a very useful device. First, it gives us a concrete way to think about tensors, one that allows a parallel to the usual matrix theory. Second, a hypermatrix is what we often get in practice: As soon as measurements are performed in some units, bases are chosen implicitly, and the values of the measurements are then recorded in the form of a hypermatrix. (There are of course good reasons not to just stick to the hypermatrix view entirely.)

We have strived to keep this chapter as elementary as possible, to show the reader that studying hypermatrices is in many instances no more difficult than studying the usual 2-dimensional matrices. Many exciting developments have to be omitted because they require too much background to describe.

Unless otherwise specified, everything discussed in this chapter applies to tensors or hypermatrices of arbitrary order $d \geq 2$ and all may be regarded as appropriate generalizations of properties of linear operators or matrices in the sense that they agree with the usual definitions when specialized to order $d = 2$. When notational simplicity is desired and when nothing essential is lost, we shall assume $d = 3$ and phrase our discussions in terms of 3-tensors. We will sometimes use the notation $\langle n \rangle := \{1, \dots, n\}$ for any $n \in \mathbb{N}$. The bases in this chapter are always implicitly ordered according to their integer indices. All vector spaces in this chapter are finite dimensional.

We use standard notation for groups and modules. S_d is the symmetric group of permutations on d elements. An S_d-module means a $\mathbb{C}[S_d]$-module, where $\mathbb{C}[S_d]$ is the set of all formal linear combinations of elements in S_d with complex coefficients (see, e.g., [AW92]). The *general linear group* of the vector space V is the group $\mathrm{GL}(V)$ of linear isomorphisms from V onto itself with operation function composition. $\mathrm{GL}(n, F)$ is the general linear group of invertible $n \times n$ matrices over F. We will however introduce a shorthand for products of such classical groups, writing

$$\mathrm{GL}(n_1, \dots, n_d, F) := \mathrm{GL}(n_1, F) \times \cdots \times \mathrm{GL}(n_d, F),$$

and likewise for $\mathrm{SL}(n_1, \dots, n_d, F)$ (where $\mathrm{SL}(n, F)$ is the special linear group of $n \times n$ matrices over F having determinant one) and $\mathrm{U}(n_1, \dots, n_d, \mathbb{C})$ (where $\mathrm{U}(n, \mathbb{C})$ is the group of $n \times n$ unitary matrices).

In this chapter, as in most other discussions of tensors in mathematics, we use $\otimes$ in multiple ways: (i) When applied to abstract vector spaces U, V, W, the notation $U \otimes V \otimes W$ is a tensor product space as defined in Section 15.2; (ii) when applied to vectors $\mathbf{u}, \mathbf{v}, \mathbf{w}$ from abstract vector spaces U, V, W, the notation $\mathbf{u} \otimes \mathbf{v} \otimes \mathbf{w}$ is a symbol for a special element of $U \otimes V \otimes W$; (iii) when applied to l-, m-, n-tuples in F^l, F^m, F^n, it means the Segre outer product as defined in Section 15.1; (iv) when applied to F^l, F^m, F^n, $F^l \otimes F^m \otimes F^n$ means the set of all Segre outer products that can be obtained from linear combinations of terms like those in Eq. (15.3). Nonetheless, they are all consistent with each other.

15.1 Hypermatrices

What is the difference between an $m \times n$ matrix $A \in \mathbb{C}^{m \times n}$ and a mn-tuple $\mathbf{a} \in \mathbb{C}^{mn}$? The immediate difference is a superficial one: Both are lists of mn complex numbers except that we usually write A as a 2-dimensional array of numbers and $\mathbf{a}$ as a 1-dimensional array of numbers. The more important distinction comes from consideration of the natural group actions on $\mathbb{C}^{m \times n}$ and $\mathbb{C}^{mn}$. One may multiply $A \in \mathbb{C}^{m \times n}$ on "two sides" independently by an $m \times m$ matrix and an $n \times n$ matrix, whereas one may only multiply $\mathbf{a} \in \mathbb{C}^{mn}$ on "one side" by an $mn \times mn$ matrix. In algebraic parlance, $\mathbb{C}^{m \times n}$ is a $\mathbb{C}^{m \times m} \times \mathbb{C}^{n \times n}$-module whereas $\mathbb{C}^{mn}$ is a $\mathbb{C}^{mn \times mn}$-module. This extends to any order-d hypermatrices (i.e., d-dimensional matrices).

In Sections 15.3 to 15.9 we will be discussing various properties of hypermatrices and tensors. Most of these are generalizations of well-known notions for matrices or order-2 tensors. Since the multitude of indices when discussing an order-d hypermatrix can be distracting, for many of the discussions we assume that $d = 3$. The main differences between usual matrices and hypermatrices come from the transition from $d = 2$ to $d = 3$. An advantage of emphasizing 3-hypermatrices is that these may be conveniently written down on a 2-dimensional piece of paper as a list of usual matrices. This is illustrated in the examples.

Definitions:

For $n_1, \ldots, n_d \in \mathbb{N}$, a function $f : \langle n_1 \rangle \times \cdots \times \langle n_d \rangle \to F$ is a (complex) **hypermatrix**, also called an **order-d hypermatrix** or **d-hypermatrix**. We often just write $a_{k_1 \cdots k_d}$ to denote the value $f(k_1, \ldots, k_d)$ of f at $(k_1, \ldots, k_d)$ and think of f (renamed as A) as specified by a d-dimensional table of values, writing $A = [a_{k_1 \cdots k_d}]_{k_1, \ldots, k_d = 1}^{n_1, \ldots, n_d}$, or $A = [a_{k_1 \cdots k_d}]$.

The set of order-d hypermatrices (with domain $\langle n_1 \rangle \times \cdots \times \langle n_d \rangle$) is denoted by $F^{n_1 \times \cdots \times n_d}$, and we define **entrywise addition** and **scalar multiplication**: For any $[a_{k_1 \cdots k_d}], [b_{k_1 \cdots k_d}] \in F^{n_1 \times \cdots \times n_d}$ and $\gamma \in F$, $[a_{k_1 \cdots k_d}] + [b_{k_1 \cdots k_d}] := [a_{k_1 \cdots k_d} + b_{k_1 \cdots k_d}]$ and $\gamma [a_{k_1 \cdots k_d}] := [\gamma a_{k_1 \cdots k_d}]$.

The **standard basis** for $F^{n_1 \times \cdots \times n_d}$ is $\mathcal{E} := \{E_{k_1 k_2 \cdots k_d} : 1 \le k_1 \le n_1, \ldots, 1 \le k_d \le n_d\}$ where $E_{k_1 k_2 \cdots k_d}$ denotes the hypermatrix with 1 in the $(k_1, k_2, \ldots, k_d)$-coordinate and 0s everywhere else.

Let $X_1 = [x_{ij}^{(1)}] \in F^{m_1 \times n_1}, \ldots, X_d = [x_{ij}^{(d)}] \in F^{m_d \times n_d}$ and $A \in F^{n_1 \times \cdots \times n_d}$. Define **multilinear matrix multiplication** by $A' = (X_1, \ldots, X_d) \cdot A \in F^{m_1 \times \cdots \times m_d}$ where

$$a'_{j_1 \cdots j_d} = \sum\nolimits_{k_1, \ldots, k_d = 1}^{n_1, \ldots, n_d} x_{j_1 k_1}^{(1)} \cdots x_{j_d k_d}^{(d)} a_{k_1 \cdots k_d} \quad \text{for } j_1 \in \langle m_1 \rangle, \ldots, j_d \in \langle m_d \rangle. \tag{15.1}$$

For any $\pi \in S_d$, the **π-transpose** of $A = [a_{j_1 \cdots j_d}] \in F^{n_1 \times \cdots \times n_d}$ is

$$A^\pi := [a_{j_{\pi(1)} \cdots j_{\pi(d)}}] \in F^{n_{\pi(1)} \times \cdots \times n_{\pi(d)}}. \tag{15.2}$$

If $n_1 = \cdots = n_d = n$, then a hypermatrix $A \in F^{n \times n \times \cdots \times n}$ is called **cubical** or **hypercubical** of dimension n.

A cubical hypermatrix $A = [a_{j_1 \cdots j_d}] \in F^{n \times n \times \cdots \times n}$ is said to be **symmetric** if $A^\pi = A$ for every $\pi \in S_d$ and **skew-symmetric** or **anti-symmetric** or **alternating** if $A^\pi = \operatorname{sgn}(\pi) A$ for every $\pi \in S_d$.

The **Segre outer product** of $\mathbf{a} = [a_i] \in F^\ell$, $\mathbf{b} = [b_j] \in F^m$, $\mathbf{c} = [c_k] \in F^n$ is

$$\mathbf{a} \otimes \mathbf{b} \otimes \mathbf{c} := [a_i b_j c_k]_{i,j,k=1}^{\ell, m, n} \in F^{\ell \times m \times n}. \tag{15.3}$$

Let $A \in F^{n_1 \times \cdots \times n_d}$ and $B \in F^{m_1 \times \cdots \times m_e}$ be hypermatrices of orders d and e, respectively. Then the **outer product** of A and B is a hypermatrix C of order $d + e$ denoted

$$C = A \otimes B \in F^{n_1 \times \cdots \times n_d \times m_1 \times \cdots \times m_e} \tag{15.4}$$

with its $(i_1, \ldots, i_d, j_1 \ldots, j_e)$-entry given by

$$c_{i_1 \cdots i_d j_1 \cdots j_e} = a_{i_1 \cdots i_d} b_{j_1 \cdots j_e} \tag{15.5}$$

for all $i_1 \in \langle n_1 \rangle, \ldots, i_d \in \langle n_d \rangle$ and $j_1 \in \langle m_1 \rangle, \ldots, j_e \in \langle m_e \rangle$.

Suppose $A \in F^{n_1 \times \cdots \times n_{d-1} \times n}$ and $B \in F^{n \times m_2 \times \cdots \times m_e}$ are an order-d and an order-e hypermatrix, respectively, where the last index i_d of A and the first index j_1 of B run over the same range, i.e., $i_d \in \langle n \rangle$ and $j_1 \in \langle n \rangle$. The **contraction product** of A and B is an order-$(d + e - 2)$ hypermatrix $C \in F^{n_1 \times \cdots \times n_{d-1} \times m_2 \times \cdots \times m_e}$ whose entries are

$$c_{i_1 \cdots i_{d-1} j_2 \cdots j_e} = \sum\nolimits_{k=1}^{n} a_{i_1 \cdots i_{d-1} k} b_{k j_2 \cdots j_e}, \tag{15.6}$$

for $i_1 \in \langle n_1 \rangle, \ldots, i_{d-1} \in \langle n_{d-1} \rangle$ and $j_2 \in \langle m_2 \rangle, \ldots, j_e \in \langle m_e \rangle$.

In general if $A \in F^{n_1\times\cdots\times n_d}$ and $B \in F^{m_1\times\cdots\times m_e}$ have an index with a common range, say, $n_p = m_q = n$, then $C \in F^{n_1\times\cdots\times\widehat{n}_p\times\cdots\times n_d\times m_1\times\cdots\times\widehat{m}_q\times\cdots\times m_e}$ is the hypermatrix with entries

$$c_{i_1\cdots\widehat{i}_p\cdots i_d j_1\cdots\widehat{j}_q\cdots j_e} = \sum\nolimits_{k=1}^{n} a_{i_1\cdots k\cdots i_d} b_{j_1\cdots k\cdots j_e}. \tag{15.7}$$

where by convention a caret over any entry means that the respective entry is omitted (e.g., $a_{i\widehat{j}k} = a_{ik}$ and $F^{\widehat{l}\times m\times n} = F^{m\times n}$).

Contractions are not restricted to one pair of indices at a time. For hypermatrices A and B, the hypermatrix

$$\langle A, B\rangle_{\alpha:\lambda,\beta:\mu,\ldots,\gamma:\nu}$$

is the hypermatrix obtained from contracting the αth index of A with the λth index of B, the βth index of A with the μth index of $B, \ldots,$ the γth index of A with the νth index of B (assuming that the indices that are contracted run over the same range and in the same order).

Facts:

Facts requiring proof for which no specific reference is given can be found in [Lim] and the references therein.

1. $F^{n_1\times\cdots\times n_d}$ with entrywise addition and scalar multiplication is a vector space.
2. The standard basis $\mathcal{E}$ is a basis for $F^{n_1\times n_2\times\cdots\times n_d}$, and $\dim F^{n_1\times n_2\times\cdots\times n_d} = n_1 n_2\cdots n_d$.
3. The elements of the standard basis of $F^{n_1\times\cdots\times n_d}$ may be written as
$$E_{k_1k_2\cdots k_d} = \mathbf{e}_{k_1}\otimes\mathbf{e}_{k_2}\otimes\cdots\otimes\mathbf{e}_{k_d},$$
using the Segre outer product (15.3).
4. Let $A \in F^{n_1\times\cdots\times n_d}$ and $X_k \in F^{l_k\times m_k}$, $Y_k \in F^{m_k\times n_k}$ for $k = 1,\ldots,d$. Then
$$(X_1,\ldots,X_d)\cdot[(Y_1,\ldots,Y_d)\cdot A] = (X_1Y_1,\ldots,X_dY_d)\cdot A.$$
5. Let $A, B \in F^{n_1\times\cdots\times n_d}$, $\alpha,\beta \in F$, and $X_k \in F^{m_k\times n_k}$ for $k = 1,\ldots,d$. Then
$$(X_1,\ldots,X_d)\cdot[\alpha A + \beta B] = \alpha(X_1,\ldots,X_d)\cdot A + \beta(X_1,\ldots,X_d)\cdot B.$$
6. Let $A \in F^{n_1\times\cdots\times n_d}$, $\alpha,\beta \in F$, and $X_k, Y_k \in F^{m_k\times n_k}$ for $k = 1,\ldots,d$. Then
$$[\alpha(X_1,\ldots,X_d) + \beta(Y_1,\ldots,Y_d)]\cdot A = \alpha(X_1,\ldots,X_d)\cdot A + \beta(Y_1,\ldots,Y_d)\cdot A.$$
7. The Segre outer product interacts with multilinear matrix multiplication in the following manner
$$(X_1,\ldots,X_d)\cdot\left[\sum\nolimits_{p=1}^{r}\beta_p\mathbf{v}_p^{(1)}\otimes\cdots\otimes\mathbf{v}_p^{(d)}\right] = \sum\nolimits_{p=1}^{r}\beta_p(X_1\mathbf{v}_p^{(1)})\otimes\cdots\otimes(X_d\mathbf{v}_p^{(d)}).$$
8. For cubical hypermatrices, each $\pi \in S_d$ defines a linear operator
$$\pi : F^{n\times\cdots\times n} \to F^{n\times\cdots\times n},\ \pi(A) = A^{\pi}.$$
9. Any matrix $A \in F^{n\times n}$ may be written as a sum of a symmetric and a skew symmetric matrix, $A = \frac{1}{2}(A+A^T)+\frac{1}{2}(A-A^T)$. This is *not* true for hypermatrices of order $d > 2$. For example, for a 3-hypermatrix $A \in F^{n\times n\times n}$, the equivalent of the decomposition is
$$\begin{aligned} A = {} & \frac{1}{6}(A+A^{(1,2,3)}+A^{(1,3,2)}+A^{(1,2)}+A^{(1,3)}+A^{(2,3)})+\frac{1}{3}(A+A^{(1,2)}-A^{(1,3)}-A^{(1,2,3)}) \\ & +\frac{1}{3}(A+A^{(1,3)}-A^{(1,2)}-A^{(1,3,2)})+\frac{1}{6}(A+A^{(1,2,3)}+A^{(1,3,2)}-A^{(1,2)}-A^{(1,3)}-A^{(2,3)}), \end{aligned}$$
where $S_3 = \{1,(1,2),(1,3),(2,3),(1,2,3),(1,3,2)\}$ (a 3-hypermatrix has five different "transposes" in addition to the original).

10. When $d = e = 2$, the contraction of two matrices is simply the matrix-matrix product: If $A \in F^{m\times n}$ and $B \in F^{n\times p}$, then $C \in F^{m\times p}$ is given by $C = AB$, $c_{ij} = \sum_{k=1}^{n} a_{ik}b_{kj}$.
11. When $d = e = 1$, the contraction of two vectors $a \in \mathbb{R}^n$ and $b \in \mathbb{R}^n$ is the scalar $c \in \mathbb{R}$ given by the Euclidean inner product $c = \sum_{k=1}^{n} a_k b_k$ (for complex vectors, we contract a with $\bar{b}$ to get the Hermitian inner product).
12. The contraction product respects expressions of hypermatrices written as a sum of decomposable hypermatrices. For example, if

$$A = \sum\nolimits_{i=1}^{r} \mathbf{a}_i \otimes \mathbf{b}_i \otimes \mathbf{c}_i \in F^{l\times m\times n}, \quad B = \sum\nolimits_{j,k=1}^{s,t} \mathbf{w}_k \otimes \mathbf{x}_j \otimes \mathbf{y}_j \otimes \mathbf{z}_k \in F^{n\times p\times m\times q},$$

then

$$\Big\langle \sum\nolimits_{i=1}^{r} \mathbf{a}_i \otimes \mathbf{b}_i \otimes \mathbf{c}_i, \sum\nolimits_{j,k=1}^{s,t} \mathbf{w}_k \otimes \mathbf{x}_j \otimes \mathbf{y}_j \otimes \mathbf{z}_k \Big\rangle_{2:3,3:1} = \\ \sum\nolimits_{i,j,k=1}^{r,s,t} \langle \mathbf{b}_i, \mathbf{y}_j\rangle \langle \mathbf{c}_i, \mathbf{w}_k\rangle \mathbf{a}_i \otimes \mathbf{x}_j \otimes \mathbf{z}_k \in F^{l\times p\times q},$$

where $\langle \mathbf{b}_i, \mathbf{y}_j\rangle = \mathbf{b}_i^T \mathbf{y}_j$ and $\langle \mathbf{c}_i, \mathbf{w}_k\rangle = \mathbf{c}_i^T \mathbf{w}_k$ as usual.
13. Multilinear matrix multiplication may also be expressed as the contraction of $A \in F^{n_1\times\cdots\times n_d}$ with matrices $X_1 \in F^{m_1\times n_1}, \dots, X_d \in F^{m_d\times n_d}$. Take $d = 3$ for example; $(X, Y, Z) \cdot A$ for $A \in F^{l\times m\times n}$ and $X \in F^{p\times l}, Y \in F^{q\times m}, Z \in F^{r\times n}$ is

$$(X, Y, Z) \cdot A = \langle X, \langle Y, \langle Z, A\rangle_{2:3}\rangle_{2:2}\rangle_{2:1}.$$

Note that the order of contractions does not matter, i.e.,

$$\langle X, \langle Y, \langle Z, A\rangle_{2:3}\rangle_{2:2}\rangle_{2:1} = \langle Y, \langle X, \langle Z, A\rangle_{2:3}\rangle_{2:1}\rangle_{2:2} = \cdots = \langle Z, \langle Y, \langle X, A\rangle_{2:1}\rangle_{2:2}\rangle_{2:3}.$$

14. For the special case where we contract two hypermatrices $A, B \in \mathbb{C}^{n_1\times\cdots\times n_d}$ in all indices to get a scalar in $\mathbb{C}$, we shall drop all indices and denote it by

$$\langle A, B\rangle = \sum\nolimits_{j_1,\dots,j_d=1}^{n_1,\dots,n_d} a_{j_1\cdots j_d} b_{j_1\cdots j_d}.$$

If we replace B by its complex conjugate, this gives the usual Hermitian inner product.

Examples:

1. A 3-hypermatrix $A \in \mathbb{C}^{l\times m\times n}$ has “three sides” and may be multiplied by three matrices $X \in \mathbb{C}^{p\times l}$, $Y \in \mathbb{C}^{q\times m}$, $Z \in \mathbb{C}^{r\times n}$. This yields another 3-hypermatrix $A' \in \mathbb{C}^{p\times q\times r}$ where

$$A' = (X, Y, Z) \cdot A \in \mathbb{C}^{p\times q\times r}, \quad a'_{\alpha\beta\gamma} = \sum\nolimits_{i,j,k=1}^{l,m,n} x_{\alpha i} y_{\beta j} z_{\gamma k} a_{ijk}.$$

2. A 3-hypermatrix may be conveniently written down on a (2-dimensional) piece of paper as a list of usual matrices, called *slices*. For example $A = [a_{ijk}]_{i,j,k=1}^{4,3,2} \in \mathbb{C}^{4\times 3\times 2}$ can be written down as two “slices” of 4×3 matrices

$$A = \left[\begin{array}{ccc|ccc} a_{111} & a_{121} & a_{131} & a_{112} & a_{122} & a_{132} \\ a_{211} & a_{221} & a_{231} & a_{212} & a_{222} & a_{232} \\ a_{311} & a_{321} & a_{331} & a_{312} & a_{322} & a_{332} \\ a_{411} & a_{421} & a_{431} & a_{412} & a_{422} & a_{432} \end{array}\right] \in \mathbb{C}^{4\times 3\times 2}$$

where i, j, k index the row, column, and slice, respectively.

3. More generally a 3-hypermatrix $A \in \mathbb{C}^{l \times m \times n}$ can be written down as n slices of $l \times m$ matrices $A_k \in \mathbb{C}^{l \times m}$, $k = 1, \ldots, n$, denoted
$$A = [A_1 \mid A_2 \mid \cdots \mid A_n] \in \mathbb{C}^{l \times m \times n}.$$
If $A = [a_{ijk}]_{i,j,k=1}^{l,m,n}$, then $A_k = [a_{ijk}]_{i,j=1}^{l,m}$.
4. A related alternative way is to introduce indeterminates $x_1, \ldots, x_n$ and represent $A \in \mathbb{C}^{l \times m \times n}$ as a matrix whose entries are linear polynomials in $x_1, \ldots, x_n$:
$$x_1 A_1 + x_2 A_2 + \cdots + x_n A_n \in \mathbb{C}[x_1, \ldots, x_n]^{l \times m}.$$
Clearly, we have a one-to-one correspondence between $l \times m \times n$ hypermatrices in $\mathbb{C}^{l \times m \times n}$ and $l \times m$ matrices in $\mathbb{C}[x_1, \ldots, x_n]^{l \times m}$.
5. Just like a matrix can be sliced up into rows or columns, we may of course also slice up a 3-hypermatrix in two other ways: as l slices of $m \times n$ matrices or m slices of $l \times n$ matrices. To avoid notational clutter, we shall not introduce additional notations for these but simply note that these correspond to looking at the slices of the π-tranposes of A (just like the rows of a matrix $A \in \mathbb{C}^{m \times n}$ are the columns of its transpose $A^T \in \mathbb{C}^{n \times m}$).

Applications:

1. [Bax78, Yan67] In statistical mechanics, the Yang–Baxter equation is given by
$$\sum\nolimits_{\alpha,\beta,\gamma=1}^{N} R_{\ell\gamma i\alpha} R_{\alpha\beta jk} R_{mn\gamma\beta} = \sum\nolimits_{\alpha,\beta,\gamma=1}^{N} R_{\alpha\beta jk} R_{\ell m\alpha\gamma} R_{\gamma n\beta k}$$
where $i, j, k, \ell, m, n = 1, \ldots, N$. This may be written in terms of contractions of hypermatrices. Let $R = (R_{ijkl}) \in \mathbb{C}^{N \times N \times N \times N}$, then we have
$$\langle \langle R, R \rangle_{4:1}, R \rangle_{2:3,4:4} = \langle R, \langle R, R \rangle_{4:1} \rangle_{1:3,2:4}.$$
2. Hooke's law in one spatial dimension, with $x =$ extension, $F =$ force, $c =$ the spring constant, is $F = -cx$. Hooke's law in three spatial dimensions is given by the linear elasticity equation:
$$\sigma_{ij} = \sum\nolimits_{k,l=1}^{3} c_{ijkl} \gamma_{kl}.$$
where $\mathbf{x} = [x_1, x_2, x_3]$, $C = [c_{ijkl}] \in \mathbb{R}^{3 \times 3 \times 3 \times 3}$ is the elasticity tensor (also called stiffness tensor), $\Sigma \in \mathbb{R}^{3 \times 3}$ is the stress tensor, and $\Gamma \in \mathbb{R}^{3 \times 3}$ is strain tensor. Hooke's law may be expressed in terms of contraction product as
$$\Sigma = \langle C, \Gamma \rangle_{3:1,4:2}.$$
3. The observant reader might have noted that the word "tensor" was used to denote a tensor of order 2. The stress and strain tensors are all of order 2. This is in fact the most common use of the term "tensors" in physics, where order-2 tensors occur a lot more frequently than those of higher orders. There are authors (cf. [Bor90], for example) who use the term "tensor" to mean exclusively a tensor of order 2.

15.2 Tensors and Multilinear Functionals

There is a trend in modern mathematics where instead of defining a mathematical entity (like a tensor) directly, one first defines a whole space of such entities (like a space of tensors) and subsequently defines the entity as an element of this space. For example, a succinct answer to the question "What is a vector?" is, "It is an element of a vector space" [Hal85, p. 153]. One advantage of such an approach is that it allows us to examine the entity in the appropriate context. Depending on the context, a matrix can be an element of a vector space $F^{n\times n}$, of a ring, e.g., the endomorphism ring $L(F^n)$ of F^n, of a Lie algebra, e.g., $\mathfrak{gl}(n, F)$, etc. Depending on what properties of the matrix one is interested in studying, one chooses the space it lives in accordingly.

The same philosophy applies to tensors, where one first defines a tensor product of d vector spaces $V_1 \otimes \cdots \otimes V_d$ and then subsequently defines an order-d tensor as an element of such a tensor product space. Since a tensor product space is defined via a universal factorization property (the definition used in Section 14.2), it can be interpreted in multiple ways, such as a quotient module (the equivalent definition used here) or a space of multilinear functionals. We will regard tensors as multilinear functionals. A perhaps unconventional aspect of our approach is that for clarity we isolate the notion of covariance and contravariance (see Section 15.10) from our definition of a tensor. We do not view this as an essential part of the definition but a source of obfuscation.

Tensors can also be represented as hypermatrices by choosing a basis. Given a set of bases, the essential information about a tensor T is captured by the coordinates $a_{j_1\cdots j_d}$'s (cf. Fact 3 below). We may view the coefficient $a_{j_1\cdots j_d}$ as the $(j_1, \ldots, j_d)$-entry of the d-dimensional matrix $A = [a_{j_1\cdots j_d}] \in F^{n_1\times\cdots\times n_d}$, where A is a coordinate representation of T with respect to the specified bases.

See also Section 14.2 for more information on tensors and tensor product spaces.

Definitions:

Let F be a field and let $V_1, \ldots, V_d$ be F-vector spaces.

The **tensor product space** $V_1 \otimes \cdots \otimes V_d$ is the quotient module $F(V_1, \ldots, V_d)/R$ where $F(V_1, \ldots, V_d)$ is the free module generated by all n-tuples $(\mathbf{v}_1, \ldots, \mathbf{v}_d) \in V_1 \times \cdots \times V_d$ and R is the submodule of $F(V_1, \ldots, V_d)$ generated by elements of the form

$$(\mathbf{v}_1, \ldots, \alpha\mathbf{v}_k + \beta\mathbf{v}_k', \ldots, \mathbf{v}_d) - \alpha(\mathbf{v}_1, \ldots, \mathbf{v}_k, \ldots, \mathbf{v}_d) - \beta(\mathbf{v}_1, \ldots, \mathbf{v}_k', \ldots, \mathbf{v}_d)$$

for all $\mathbf{v}_k, \mathbf{v}_k' \in V_k$, $\alpha, \beta \in F$, and $k \in \{1, \ldots, d\}$. We write $\mathbf{v}_1\otimes\cdots\otimes\mathbf{v}_d$ for the element $(\mathbf{v}_1, \ldots, \mathbf{v}_d)+R$ in the quotient space F/R.

An element of $V_1\otimes\cdots\otimes V_d$ that can be expressed in the form $\mathbf{v}_1\otimes\cdots\otimes\mathbf{v}_d$ is called **decomposable**. The symbol $\otimes$ is called the **tensor product** when applied to vectors from abstract vector spaces.

The elements of $V_1 \otimes \cdots \otimes V_d$ are called **order-d tensors** or **d-tensors** and $n_k = \dim V_k$, $k = 1, \ldots, d$ are the **dimensions** of the tensors.

Let $\mathcal{B}_k = \{\mathbf{b}_1^{(k)}, \ldots, \mathbf{b}_{n_k}^{(k)}\}$ be a basis for $V_k, k = 1, \ldots, d$. For a tensor $T \in V_1 \otimes \cdots \otimes V_d$, the **coordinate representation** of T with respect to the specified bases is $[T]_{\mathcal{B}_1,\ldots,\mathcal{B}_d} = [a_{j_1\cdots j_d}]$. where

$$T = \sum\nolimits_{j_1,\ldots,j_d=1}^{n_1,\ldots,n_d} a_{j_1\cdots j_d}\mathbf{b}_{j_1}^{(1)} \otimes \cdots \otimes \mathbf{b}_{j_d}^{(d)}. \tag{15.8}$$

The special case where $V_1 = \cdots = V_d = V$ is denoted $\mathsf{T}^d(V)$ or $V^{\otimes d}$, i.e., $\mathsf{T}^d(V) = V \otimes \cdots \otimes V$.

For any $\pi \in S_d$, the action of π on $\mathsf{T}^d(V)$ is defined by

$$\pi(\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_d) := \mathbf{v}_{\pi(1)} \otimes \cdots \otimes \mathbf{v}_{\pi(d)} \tag{15.9}$$

for decomposable elements, and then extended linearly to all elements of $\mathsf{T}^d(V)$.

A tensor $T \in \mathsf{T}^d(V)$ is **symmetric** if $\pi(T) = T$ for all $\pi \in S_d$ and is **alternating** if $\pi(T) = \operatorname{sgn}(\pi)T$ for all $\pi \in S_d$.

For a vector space V, V^* denotes the **dual space** of linear functionals of V (cf. Section 3.6).

A multilinear functional on $V_1, \ldots, V_d$ is a function $T : V_1 \times V_2 \times \cdots \times V_d \to F$, i.e., for $\alpha, \beta \in F$,

$$T(\mathbf{x}_1,\ldots,\alpha\mathbf{y}_k+\beta\mathbf{z}_k,\ldots,\mathbf{x}_d)=\alpha T(\mathbf{x}_1,\ldots,\mathbf{y}_k,\ldots,\mathbf{x}_d)+\beta T(\mathbf{x}_1,\ldots,\mathbf{z}_k,\ldots,\mathbf{x}_d), \tag{15.10}$$

for every $k=1,\ldots,d$.

The vector space of (F-valued) multilinear functionals on $V_1,\ldots,V_d$ is denoted by $L(V_1,\ldots,V_d;F)$.

A multilinear functional $T\in L(V_1,\ldots,V_d;F)$ is **decomposable** if $T=\theta_1\cdots\theta_d$ where $\theta_i\in V_i^*$ and $\theta_1\cdots\theta_d(\mathbf{v}_1,\ldots,\mathbf{v}_d)=\theta_1(\mathbf{v}_1)\cdots\theta_d(\mathbf{v}_d)$.

For any $\pi\in S_d$, the action of π on $L(V,\ldots,V,F)$ is defined by

$$\pi(T)(\mathbf{v}_1,\ldots,\mathbf{v}_d)=T(\mathbf{v}_{\pi(1)},\ldots,\mathbf{v}_{\pi(d)}). \tag{15.11}$$

A multilinear functional $T\in L(V_1,\ldots,V_d;F)$ is **symmetric** if $\pi(T)=T$ for all $\pi\in S_d$ and is **alternating** if $\pi(T)=\operatorname{sgn}(\pi)T$ for all $\pi\in S_d$.

Facts:

Facts requiring proof for which no specific reference is given can be found in [Bou98, Chap. II], [KM97, Chap. 4], [Lan02, Chap. XVI], and [Yok92, Chap. 1]. Additional facts about tensors can be found in Section 14.2.

1. The tensor product space $V_1\otimes\cdots\otimes V_d$ with $\nu: V_1\times\cdots\times V_m\to V_1\otimes\cdots\otimes V_d$ defined by
$$\nu(\mathbf{v}_1,\ldots,\mathbf{v}_d)=\mathbf{v}_1\otimes\cdots\otimes\mathbf{v}_d=(\mathbf{v}_1,\ldots,\mathbf{v}_d)+R\in F(V_1,\ldots,V_d)/R$$
and extended linearly satisfies the *Universal Factorization Property* that can be used to define tensor product spaces (cf. Section 14.2), namely:

   > If φ is a multilinear map from $V_1\times\cdots\times V_d$ into the vector space U, then there exists a unique linear map ψ from $V_1\otimes\cdots\otimes V_d$ into U, that makes the following diagram commutative:
   >
   > $$\begin{tikzcd} V_1\times\cdots\times V_d \arrow[r, "\nu"] \arrow[dr, "\varphi"'] & V_1\otimes\cdots\otimes V_d \arrow[d, "\psi"] \\ & U \end{tikzcd}$$
   >
   > i.e., $\psi\nu=\varphi$.

2. If $U=F^l$, $V=F^m$, $W=F^n$, we may identify
$$F^l\otimes F^m\otimes F^n=F^{l\times m\times n}$$
through the interpretation of the tensor product of vectors as a hypermatrix via the Segre outer product (cf. Eq. (15.3)),
$$[a_1,\ldots,a_l]^T\otimes[b_1,\ldots,b_m]^T\otimes[c_1,\ldots,c_n]^T=[a_ib_jc_k]_{i,j,k=1}^{l,m,n}.$$
This is a model of the universal definition of $\otimes$ given in Section 14.2.
3. Given bases $\mathcal{B}_k=\{\mathbf{b}_1^{(k)},\ldots,\mathbf{b}_{n_k}^{(k)}\}$ for V_k, $k=1,\ldots,d$, any tensor T in $V_1\otimes\cdots\otimes V_d$, can be expressed as a linear combination
$$T=\sum\nolimits_{j_1,\ldots,j_d=1}^{n_1,\ldots,n_d}a_{j_1\cdots j_d}\mathbf{b}_{j_1}^{(1)}\otimes\cdots\otimes\mathbf{b}_{j_d}^{(d)}.$$
In older literature, the $a_{j_1\cdots j_d}$'s are often called the *components* of T.
4. One loses information when going from the tensor to its hypermatrix representation, in the sense that the bases $\mathcal{B}_1,\ldots,\mathcal{B}_d$ must be specified in addition to the hypermatrix A in order to recover the tensor T.

5. Every choice of bases on $V_1, \dots, V_d$ gives a (usually) different hypermatrix representation of the same tensor in $V_1 \otimes \cdots \otimes V_d$.
6. Given two sets of bases $\mathcal{B}_1, \dots, \mathcal{B}_d$ and $\mathcal{B}'_1, \dots, \mathcal{B}'_d$ for $V_1, \dots, V_d$, the same tensor T has two coordinate representations as a hypermatrix,

$$A = [T]_{\mathcal{B}_1,\dots,\mathcal{B}_d} \qquad \text{and} \qquad A' = [T]_{\mathcal{B}'_1,\dots,\mathcal{B}'_d}$$

where $A = [a_{k_1 \cdots k_d}]$, $A' = [a'_{k_1 \cdots k_d}] \in F^{n_1 \times \cdots \times n_d}$. The relationship between A and A' is given by the multilinear matrix multiplication

$$A' = (X_1, \dots, X_d) \cdot A$$

where $X_k \in \mathrm{GL}(n_k, F)$ is the change-of-basis matrix transforming $\mathcal{B}'_k$ to $\mathcal{B}_k$ for $k = 1, \dots, d$. We shall call this the *change-of-basis* rule. Explicitly, the entries of A' and A are related by

$$a'_{j_1 \cdots j_d} = \sum\nolimits_{k_1,\dots,k_d=1}^{n_1,\dots,n_d} x_{j_1 k_1} \cdots x_{j_d k_d} a_{k_1 \cdots k_d} \quad \text{for } j_1 \in \langle n_1 \rangle, \dots, j_d \in \langle n_d \rangle,$$

where $X_1 = [x_{j_1 k_1}] \in \mathrm{GL}(n_1, F), \dots, X_d = [x_{j_d k_d}] \in \mathrm{GL}(n_d, F)$.
7. Cubical hypermatrices arise from a natural coordinate representation of tensors $T \in \mathsf{T}^d(V)$, i.e.,

$$T : V \times \cdots \times V \to F$$

where by "natural" we mean that we make the same choice of basis $\mathcal{B}$ for every copy of V, i.e.,

$$[T]_{\mathcal{B},\dots,\mathcal{B}} = A.$$

8. $\mathsf{T}^d(V)$ is an S_d-module.
9. Symmetric and alternating hypermatrices are natural coordinate representations of symmetric and alternating tensors.
10. For finite-dimensional vector spaces $V_1, \dots, V_d$, the space $L(V_1^*, \dots, V_d^*; F)$ of multilinear functionals on the dual spaces V_i^* is naturally isomorphic to the tensor product space $V_1 \otimes \cdots \otimes V_d$, with $\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_d \leftrightarrow \hat{\mathbf{v}}_1 \cdots \hat{\mathbf{v}}_d$ extended by linearity, where $\hat{\mathbf{v}} \in V^{**}$ is defined by $\hat{\mathbf{v}}(f) = f(\mathbf{v})$ for $f \in V^*$. Since V is naturally isomorphic to V^{**} via $\mathbf{v} \leftrightarrow \hat{\mathbf{v}}$ (cf. Section 3.6), every vector space of multilinear functionals is a tensor product space (of the dual spaces), and a multilinear functional is a tensor: A decomposable multilinear functional $T = \theta_1 \cdots \theta_d \in L(V_1, \dots, V_d; F)$ with $\theta_i \in V_i^*$ is naturally associated with $\theta_1 \otimes \cdots \otimes \theta_d \in V_1^* \otimes \cdots \otimes V_d^*$, and this relationship is extended by linearity.
11. A multilinear functional is decomposable as a multilinear functional if and only if it is a decomposable tensor.
12. Let $\mathcal{B}_k = \{\mathbf{b}_1^{(k)}, \dots, \mathbf{b}_{n_k}^{(k)}\}$ be a basis for the vector space V_k for $k = 1, \dots, d$, so $V_k \cong F^{n_k}$ where $n_k = \dim V_k$, with the isomorphism $\mathbf{x} \mapsto [\mathbf{x}]$ where $[\mathbf{x}]$ denotes the coordinate vector with respect to basis $\mathcal{B}_k$. For a multilinear functional $T : V_1 \times \cdots \times V_d \to F$, define $a_{j_1 \cdots j_d} := T(\mathbf{b}_{j_1}^{(1)}, \dots, \mathbf{b}_{j_d}^{(d)})$ for $j_i \in \langle n_i \rangle$. Then T has the explicit formula

$$T(\mathbf{x}_1, \dots, \mathbf{x}_d) = \sum\nolimits_{j_1,\dots,j_d=1}^{n_1,\dots,n_d} a_{j_1 \cdots j_d} x_{j_1}^{(1)} \cdots x_{j_d}^{(d)},$$

in terms of the coordinates of the coordinate vector $[\mathbf{x}_k] = [x_1^{(k)}, \dots, x_{n_k}^{(k)}]^T \in F^{n_k}$ for $k = 1, \dots, d$. In older literature, the $a_{j_1 \cdots j_d}$'s are also often called the *components* of T as in Fact 3.

13. Let $\mathcal{B}_k = \{\mathbf{b}_1^{(k)}, \dots, \mathbf{b}_{n_k}^{(k)}\}$ be a basis for V_k for $k = 1, \dots, d$.
    (a) For each $i_1 \in \langle n_1 \rangle, \dots, i_d \in \langle n_d \rangle$, define the multilinear functional $\varphi_{i_1 \cdots i_d} : V_1 \times \cdots \times V_d \to F$ by
    $$\varphi_{i_1 \cdots i_d}(\mathbf{b}_{j_1}^{(1)}, \dots, \mathbf{b}_{j_d}^{(d)}) = \begin{cases} 1 & \text{if } i_1 = j_1, \dots, i_d = j_d, \\ 0 & \text{otherwise,} \end{cases}$$
    and extend the definition to all of $V_1 \times \cdots \times V_d$ via (15.10). The set
    $$\mathcal{B}^* := \{\varphi_{i_1 \cdots i_d} : i_1 \in \langle n_1 \rangle, \dots, i_d \in \langle n_d \rangle\}$$
    is a basis for $L(V_1, \dots, V_d; F)$.
    (b) The set
    $$\mathcal{B} := \left\{\mathbf{b}_{j_1}^{(1)} \otimes \cdots \otimes \mathbf{b}_{j_d}^{(d)} : j_1 \in \langle n_1 \rangle, \dots, j_d \in \langle n_d \rangle\right\}$$
    is a basis for $V_1 \otimes \cdots \otimes V_d$.
    (c) For a multilinear functional $T : V_1 \times \cdots \times V_d \to F$ with $a_{j_1 \cdots j_d}$ as defined in Fact 12, $T = \sum_{j_1, \dots, j_d = 1}^{n_1, \dots, n_d} a_{j_1 \cdots j_d} \varphi_{j_1 \cdots j_d}$.
    (d) $\dim V_1 \otimes \cdots \otimes V_d = \dim V_1 \cdots \dim V_d$ since $|\mathcal{B}^*| = |\mathcal{B}| = n_1 \cdots n_d$.
14. $\mathsf{T}^d(V)$ is an $\mathrm{End}(V)$-module (where $\mathrm{End}(V)$ is the algebra of linear operators on V) with the natural action defined on decomposable elements via
    $$g(\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_d) = g(\mathbf{v}_1) \otimes \cdots \otimes g(\mathbf{v}_d)$$
    for any $g \in \mathrm{End}(V)$ and then extended linearly to all of $\mathsf{T}^d(V)$.

Examples:

For notational convenience, let $d = 3$.

1. Explicitly, the definition of a tensor product space above simply means that
   $$U \otimes V \otimes W := \left\{\sum\nolimits_{i=1}^{n} \alpha_i \mathbf{u}_i \otimes \mathbf{v}_i \otimes \mathbf{w}_i : \mathbf{u}_i \in U, \mathbf{v}_i \in V, \mathbf{w}_i \in W, n \in \mathbb{N}\right\}$$
   where $\otimes$ satisfies
   $$\begin{aligned} (\alpha \mathbf{v}_1 + \beta \mathbf{v}_1') \otimes \mathbf{v}_2 \otimes \mathbf{v}_3 &= \alpha \mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3 + \beta \mathbf{v}_1' \otimes \mathbf{v}_2 \otimes \mathbf{v}_3, \\ \mathbf{v}_1 \otimes (\alpha \mathbf{v}_2 + \beta \mathbf{v}_2') \otimes \mathbf{v}_3 &= \alpha \mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3 + \beta \mathbf{v}_1 \otimes \mathbf{v}_2' \otimes \mathbf{v}_3, \\ \mathbf{v}_1 \otimes \mathbf{v}_2 \otimes (\alpha \mathbf{v}_3 + \beta \mathbf{v}_3') &= \alpha \mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3 + \beta \mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3'. \end{aligned}$$
   The "modulo relation" simply means that $\otimes$ obeys these rules. The statement that $\mathbf{u} \otimes \mathbf{v} \otimes \mathbf{w}$ are generators of $U \otimes V \otimes W$ simply means that $U \otimes V \otimes W$ is the set of all possible linear combinations of the form $\mathbf{u} \otimes \mathbf{v} \otimes \mathbf{w}$ where $\mathbf{u} \in U$, $\mathbf{v} \in V$, $\mathbf{w} \in W$.
2. We emphasize here that a tensor and a hypermatrix are quite different. To specify a tensor $T \in V_1 \otimes \cdots \otimes V_d$, we need both the hypermatrix $[T]_{\mathcal{B}_1, \dots, \mathcal{B}_d} \in \mathbb{C}^{n_1 \times \cdots \times n_d}$ and the bases $\mathcal{B}_1, \dots, \mathcal{B}_d$ that we chose for $V_1, \dots, V_d$.
3. Each hypermatrix in $F^{n_1 \times \cdots \times n_d}$ has a unique, natural tensor associated with it: the tensor in the standard basis of $F^{n_1} \otimes \cdots \otimes F^{n_d}$. (The same is true for matrices and linear operators.)

Applications:

1. In physics parlance, a decomposable tensor represents *factorizable* or *pure states*. In general, a tensor in $U \otimes V \otimes W$ will not be decomposable.

2. [Cor84] In the standard model of particle physics, a proton is made up of two up quarks and one down quark. A more precise statement is that the state of a proton is a 3-tensor

$$\frac{1}{\sqrt{2}}(\mathbf{e}_1 \otimes \mathbf{e}_1 \otimes \mathbf{e}_2 - \mathbf{e}_2 \otimes \mathbf{e}_1 \otimes \mathbf{e}_1) \in V \otimes V \otimes V$$

   where V is a 3-dimensional inner product space spanned by orthonormal vectors $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ that have the following interpretation:

$$\begin{aligned} \mathbf{e}_1 &= \text{state of the up quark,} \\ \mathbf{e}_2 &= \text{state of the down quark,} \\ \mathbf{e}_3 &= \text{state of the strange quark,} \end{aligned}$$

   and thus

$$\mathbf{e}_i \otimes \mathbf{e}_j \otimes \mathbf{e}_k = \text{composite state of the three quark states } e_i, e_j, e_k.$$

3. In physics, the question "What is a tensor?" is often taken to mean "What kind of physical quantities should be represented by tensors?" It is often cast in the form of questions such as "Is elasticity a tensor?", "Is gravity a tensor?", etc. The answer is that the physical quantity in question is a tensor if it obeys the change-of-bases rule in Fact 15.2.6: A d-tensor is an object represented by a list of numbers $a_{j_1 \cdots j_d} \in \mathbb{C}$, $j_k = 1, \ldots, n_k$, $k = 1, \ldots, d$, once a basis is chosen, but only if these numbers transform themselves as expected when one changes the basis.
4. Elasticity is an order-4 tensor and may be represented by a hypermatrix $C \in \mathbb{R}^{3\times3\times3\times3}$. If we measure stress using a different choice of coordinates (i.e., different basis), then the new hypermatrix representation $C' \in \mathbb{R}^{3\times3\times3\times3}$ must be related to C via

$$C' = (X, X, X, X) \cdot C \tag{15.12}$$

   where $X \in \mathrm{GL}(3, \mathbb{R})$ is the change-of-basis matrix, and Eq. (15.12) is defined according to Fact 6

$$c'_{pqrs} = \sum\nolimits_{i,j,k,l=1}^{3} x_{pi} x_{qj} x_{rk} x_{sl} c_{ijkl}, \qquad p, q, r, s = 1, 2, 3. \tag{15.13}$$

5. Let $\mathfrak{A}$ be an algebra over a field $\mathbb{F}$, i.e., a vector space on which a notion of vector multiplication $\cdot : \mathfrak{A} \times \mathfrak{A} \to \mathfrak{A}$, $(a, b) \mapsto a \cdot b$ is defined. Let $\mathcal{B} = \{\mathbf{e}_1, \ldots, \mathbf{e}_n\}$ be a basis for $\mathfrak{A}$. Then $\mathfrak{A}$ is completely determined by the hypermatrix $C = [c_{ijk}] \in \mathbb{F}^{n\times n\times n}$ where

$$\mathbf{e}_i \cdot \mathbf{e}_j = \sum_{k=1}^{n} c_{ijk} \mathbf{e}_k.$$

   The n^3 entries of C are often called the *structure constants* of $\mathfrak{A}$. This hypermatrix is the coordinate representation of a tensor in $\mathfrak{A} \otimes \mathfrak{A} \otimes \mathfrak{A}$ with respect to the basis $\mathcal{B}$. If we had chosen a new basis $\mathcal{B}'$, then the new coordinate representation C' would be related to C as in Fact 6 — in this case $C' = (X, X, X) \cdot C$ where X is the change of basis matrix from $\mathcal{B}$ to $\mathcal{B}'$. Note that this says that the entries of the hypermatrix of structure constants are coordinates of a tensor with respect to a basis.
6. For an explicit example, the Lie algebra $\mathfrak{so}(3)$ is the set of all skew-symmetric matrices in $\mathbb{R}^{3\times3}$. A basis is given by

$$Z_1 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}, \quad Z_2 = \begin{bmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}, \quad Z_3 = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

The product $\cdot$ for $\mathfrak{so}(3)$ is the commutator product $[X,Y]=XY-YX$. Note that $[Y,X]=-[X,Y]$ and $[X,X]=0$. Since $[Z_1,Z_2]=Z_3$, $[Z_2,Z_3]=Z_1$, $[Z_3,Z_1]=Z_2$, the structure constants of $\mathfrak{so}(3)$ are given by the hypermatrix $\varepsilon=(\varepsilon_{ijk})\in\mathbb{R}^{3\times3\times3}$ defined by

$$\begin{aligned}\varepsilon_{ijk}&=\begin{cases}+1 & \text{if } (i,j,k)=(1,2,3),(2,3,1),(3,1,2),\\ -1 & \text{if } (i,j,k)=(1,3,2),(2,1,3),(3,2,1),\\ 0 & \text{if } i=j, j=k, k=i,\end{cases}\\ &=\frac{(i-j)(j-k)(k-i)}{2}.\end{aligned}$$

ε is often called the *Levi-Civita symbol.*

15.3 Tensor Rank

There are several equivalent ways to define the rank of a matrix which yield non-equivalent definitions on hypermatrices of higher order. We will examine two of the most common ones in this chapter: tensor rank as defined below and multilinear rank as defined in Section 15.7. Both notions are due to Frank L. Hitchcock [Hit27a, Hit27b].

Definitions:

Let F be a field.

A hypermatrix $A\in F^{n_1\times\cdots\times n_d}$ has **rank one** or **rank-1** if there exist non-zero $\mathbf{v}^{(i)}\in F^{n}$, $i=1,\dots,d$, so that $A=\mathbf{v}^{(1)}\otimes\cdots\otimes\mathbf{v}^{(d)}$ and $\mathbf{v}^{(1)}\otimes\cdots\otimes\mathbf{v}^{(d)}$ is the Segre outer product defined in Eq. (15.3).

The **rank** of a hypermatrix $A\in F^{n_1\times\cdots\times n_d}$ is defined to be the smallest r such that it may be written as a sum of r rank-1 hypermatrices, i.e.,

$$\operatorname{rank}(A):=\min\left\{r: A=\sum\nolimits_{p=1}^{r}\mathbf{v}_p^{(1)}\otimes\cdots\otimes\mathbf{v}_p^{(d)}\right\}. \tag{15.14}$$

For vector spaces $V_1,\dots,V_d$, the **rank** or **tensor rank** of $T\in V_1\otimes\cdots\otimes V_d$ is

$$\operatorname{rank}(T)=\min\left\{r: T=\sum\nolimits_{p=1}^{r}\mathbf{v}_p^{(1)}\otimes\cdots\otimes\mathbf{v}_p^{(d)}\right\}. \tag{15.15}$$

Here $\mathbf{v}_p^{(k)}$ is a vector in the abstract vector space V_k and $\otimes$ denotes tensor product as defined in Section 15.2.

A hypermatrix or a tensor has **rank zero** if and only if it is zero (in accordance with the convention that the sum over the empty set is zero).

A minimum length decomposition of a tensor or hypermatrix, i.e.,

$$T=\sum\nolimits_{p=1}^{\operatorname{rank}(T)}\mathbf{v}_p^{(1)}\otimes\cdots\otimes\mathbf{v}_p^{(d)}, \tag{15.16}$$

is called a **rank-retaining decomposition** or simply **rank decomposition**.

Facts:

Facts requiring proof for which no specific reference is given can be found in [BCS96, Chap. 19], [Lan12, Chap. 3], [Lim], and the references therein.

1. Let $A=[a_{ijk}]_{i,j,k=1}^{l,m,n}$ and $A_k=[a_{ijk}]_{i,j=1}^{l,m}$. The following are equivalent statements characterize $\operatorname{rank}(A)\le r$.

  (a) there exist $\mathbf{x}_1, \ldots, \mathbf{x}_r \in F^l$, $\mathbf{y}_1, \ldots, \mathbf{y}_r \in F^m$, and $\mathbf{z}_1, \ldots, \mathbf{z}_r \in F^m$,
  $$A = \mathbf{x}_1 \otimes \mathbf{y}_1 \otimes \mathbf{z}_1 + \cdots + \mathbf{x}_r \otimes \mathbf{y}_r \otimes \mathbf{z}_r;$$
  (b) there exist $\mathbf{x}_1, \ldots, \mathbf{x}_r \in F^l$ and $\mathbf{y}_1, \ldots, \mathbf{y}_r \in F^m$ with
  $$\operatorname{span}\{A_1, \ldots, A_n\} \subseteq \operatorname{span}\{\mathbf{x}_1\mathbf{y}_1^T, \ldots, \mathbf{x}_r\mathbf{y}_r^T\};$$
  (c) there exist diagonal $D_1, \ldots, D_n \in F^{r\times r}$ and $X \in F^{l\times r}, Y \in F^{m\times r}$,
  $$A_k = XD_kY^T, \quad k = 1, \ldots, n.$$

  The statements analogous to (1a), (1b), and (1c) with r required to be minimal characterize $\operatorname{rank}(A) = r$. A more general form of this fact is valid for for d-tensors.

2. For $A \in F^{n_1\times\cdots\times n_d}$ and $(X_1, \ldots, X_d) \in \mathrm{GL}(n_1, \ldots, n_d, F)$,
  $$\operatorname{rank}((X_1, \ldots, X_d) \cdot A) = \operatorname{rank}(A).$$
3. If $T \in V_1 \otimes \cdots \otimes V_d$, $\mathcal{B}_1, \ldots, \mathcal{B}_d$ are bases for $V_1, \ldots, V_d$ and $A = [T]_{\mathcal{B}_1,\ldots,\mathcal{B}_d} \in F^{n_1\times\cdots\times n_d}$ (where $n_k = \dim V_k$, $k = 1, \ldots, d$), then $\operatorname{rank}(A) = \operatorname{rank}(T)$.
4. Since $\mathbb{R}^{l\times m\times n} \subseteq \mathbb{C}^{l\times m\times n}$, given $A \in \mathbb{R}^{l\times m\times n}$, we may consider its rank over $\mathbb{F} = \mathbb{R}$ or $\mathbb{F} = \mathbb{C}$,
  $$\operatorname{rank}_{\mathbb{F}}(A) = \left\{r : A = \sum\nolimits_{i=1}^{r} \mathbf{x}_i \otimes \mathbf{y}_i \otimes \mathbf{z}_i,\ \mathbf{x}_i \in \mathbb{F}^l, \mathbf{y}_i \in \mathbb{F}^m, \mathbf{z}_i \in \mathbb{F}^n\right\}.$$
  Clearly $\operatorname{rank}_{\mathbb{C}}(A) \le \operatorname{rank}_{\mathbb{R}}(A)$. However, strict inequality can occur (see Example 1 next). Note for a matrix $A \in \mathbb{R}^{m\times n}$, this does not happen; we always have $\operatorname{rank}_{\mathbb{C}}(A) = \operatorname{rank}_{\mathbb{R}}(A)$.
5. When $d = 2$, Eq. (15.14) agrees with the usual definition of matrix rank and Eq. (15.15) agrees with the usual definition of rank for linear operators and bilinear forms on finite-dimensional vector spaces.
6. In certain literature, the term "rank" is often used to mean what we have called "order" in Section 15.2. We avoid such usage for several reasons, among which the fact that it does not agree with the usual meaning of rank for linear operators or matrices.

Examples:

1. The phenomenon of rank dependence on field was first observed by Bergman [Ber69]. Take linearly independent pairs of vectors $\mathbf{x}_1, \mathbf{y}_1 \in \mathbb{R}^l$, $\mathbf{x}_2, \mathbf{y}_2 \in \mathbb{R}^m$, $\mathbf{x}_3, \mathbf{y}_3 \in \mathbb{R}^n$ and set $\mathbf{z}_k = \mathbf{x}_k + i\mathbf{y}_k$ and $\bar{\mathbf{z}}_k = \mathbf{x}_k - i\mathbf{y}_k$, then
  $$\begin{aligned} A &= \mathbf{x}_1 \otimes \mathbf{x}_2 \otimes \mathbf{x}_3 + \mathbf{x}_1 \otimes \mathbf{y}_2 \otimes \mathbf{y}_3 - \mathbf{y}_1 \otimes \mathbf{x}_2 \otimes \mathbf{y}_3 + \mathbf{y}_1 \otimes \mathbf{y}_2 \otimes \mathbf{x}_3 \qquad (15.17) \\ &= \frac{1}{2}(\bar{\mathbf{z}}_1 \otimes \mathbf{z}_2 \otimes \bar{\mathbf{z}}_3 + \bar{\mathbf{z}}_1 \otimes \bar{\mathbf{z}}_2 \otimes \mathbf{z}_3). \end{aligned}$$
  One may in fact show that $\operatorname{rank}_{\mathbb{C}}(A) = 2 < 3 = \operatorname{rank}_{\mathbb{R}}(A)$.
2. An example where $\operatorname{rank}_{\mathbb{R}}(A) \le 2 < \operatorname{rank}_{\mathbb{Q}}(A)$ is given by
  $$\bar{\mathbf{z}} \otimes \mathbf{z} \otimes \bar{\mathbf{z}} + \mathbf{z} \otimes \bar{\mathbf{z}} \otimes \mathbf{z} = 2\mathbf{x} \otimes \mathbf{x} \otimes \mathbf{x} - 4\mathbf{y} \otimes \mathbf{y} \otimes \mathbf{x} + 4\mathbf{y} \otimes \mathbf{x} \otimes \mathbf{y} - 4\mathbf{x} \otimes \mathbf{y} \otimes \mathbf{y} \in \mathbb{Q}^{2\times 2\times 2},$$
  where $\mathbf{z} = \mathbf{x} + \sqrt{2}\mathbf{y}$ and $\bar{\mathbf{z}} = \mathbf{x} - \sqrt{2}\mathbf{y}$.

Applications:

1. Let $M, C, K \in \mathbb{R}^{n\times n}$ be the mass, damping, and stiffness matrices of a **viscously damped linear system** in free vibration
  $$M\ddot{\mathbf{x}}(t) + C\dot{\mathbf{x}}(t) + K\mathbf{x}(t) = 0.$$
  where M, C, K are all symmetric positive definite. The system may be decoupled using classical modal analysis [CO65] if and only if
  $$CM^{-1}K = KM^{-1}C.$$
  Formulated in hypermatrix language, this asks when $A = [M \mid C \mid K] \in \mathbb{R}^{n\times n\times 3}$ has $\operatorname{rank}(A) \le 3$.

2. The notion of tensor rank arises in several areas and a well-known one is algebraic computational complexity [BCS96], notably the complexity of matrix multiplications. This is surprisingly easy to explain. For matrices $X = [x_{ij}], Y = [y_{jk}] \in \mathbb{C}^{n\times n}$, observe that the product may be expressed as

   $$XY = \sum\nolimits_{i,j,k=1}^{n} x_{ik} y_{kj} E_{ij} = \sum\nolimits_{i,j,k=1}^{n} \varphi_{ik}(X)\varphi_{kj}(Y) E_{ij} \tag{15.18}$$

   where $E_{ij} = \mathbf{e}_i \mathbf{e}_j^* \in \mathbb{C}^{n\times n}$ has all entries 0 except 1 in the (i,j)-entry and $\varphi_{ij}(X) = \operatorname{tr}(E_{ij}^* X) = x_{ij}$ is the linear functional $\varphi_{ij} : \mathbb{C}^{n\times n} \to \mathbb{C}$ dual to E_{ij}. Let $T_n : \mathbb{C}^{n\times n} \times \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ be the map that takes a pair of matrices $(X, Y) \in \mathbb{C}^{n\times n} \times \mathbb{C}^{n\times n}$ to their product $T(X, Y) = XY \in \mathbb{C}^{n\times n}$. Then by Eq. (15.18), T_n is given by the tensor

   $$T_n = \sum\nolimits_{i,j,k=1}^{n} \varphi_{ik} \otimes \varphi_{kj} \otimes E_{ij} \in (\mathbb{C}^{n\times n})^* \otimes (\mathbb{C}^{n\times n})^* \otimes \mathbb{C}^{n\times n}. \tag{15.19}$$

   The *exponent of matrix multiplication* is then a positive number ω defined in terms of tensor rank,

   $$\omega := \inf\{\alpha : \operatorname{rank}(T_n) = O(n^\alpha),\ n \in \mathbb{N}\}.$$

   It is not hard to see that whatever the value of $\omega > 0$, there must exist $O(n^\omega)$ algorithms for multiplying $n\times n$ matrices. In fact, every r-term decomposition (15.16) of T_n yields an explicit algorithm for multiplying two $n \times n$ matrices in $O(n^{\log_2 r})$ complexity. Via elementary row operations, we may deduce that any $O(n^\omega)$ algorithm for computing matrix multiplications $(A, B) \mapsto AB$ would also yield a corresponding $O(n^\omega)$ algorithm for matrix inversion $A \mapsto A^{-1}$ (and thus for solving linear systems $Ax = b$). If we choose the standard bases $\{E_{ij} : i, j \in \langle n\rangle\}$ on $\mathbb{C}^{n\times n}$ and its dual bases $\{\varphi_{ij} : i, j \in \langle n\rangle\}$ on the dual space $(\mathbb{C}^{n\times n})^*$, then the 3-tensor T_n may be represented by a 3-hypermatrix

   $$M_n \in \mathbb{C}^{n^2\times n^2\times n^2}.$$

   The connection between the exponent of matrix multiplication and tensor rank was first noted by Strassen in [Str73]. We refer the reader to Chapter 61 and [Knu98] for very readable accounts and to [BCS96] for an extensive in-depth discussion.

3. The special case $n = 2$ is behind *Strassen's algorithm for matrix multiplication and inversion* with $O(n^{\log_2 7})$ time complexity [Str69]. We shall present it in the modern language of hypermatrices. We write $M_2 = [A_1 \mid A_2 \mid A_3 \mid A_4] \in \mathbb{C}^{4\times4\times4}$ where the matrix slices of M_2 are

   $$A_1 = \begin{bmatrix} I & O \\ O & O \end{bmatrix}, \quad A_2 = \begin{bmatrix} O & O \\ I & O \end{bmatrix}, \quad A_3 = \begin{bmatrix} O & I \\ O & O \end{bmatrix}, \quad A_4 = \begin{bmatrix} O & O \\ O & I \end{bmatrix},$$

   I and O are 2×2 identity and zero matrices. Define

   $$X = \begin{bmatrix} 1 & 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 0 & 1 & 0 \\ -1 & 0 & 1 & 1 & 0 & 1 & 0 \end{bmatrix}, \quad Y = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & -1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & -1 & 0 & 1 \end{bmatrix},$$

   $$D_1 = \operatorname{diag}(1, 0, 1, 1, 0, 0, -1), \quad D_2 = \operatorname{diag}(0, 0, -1, 0, 0, 1, 0),$$
   $$D_3 = \operatorname{diag}(0, 0, 0, 0, 1, 0, 1), \quad D_4 = \operatorname{diag}(-1, 1, 0, 0, -1, -1, 0).$$

   One may check that $XD_jY^T = A_j$ for $j = 1, 2, 3, 4$. In other words, this is a simultaneous diagaonlization of A_1, A_2, A_3, A_4 by X and Y in the sense of Fact 1 and so we conclude that $\operatorname{rank}(M_2) \le 7$. In fact, it has been shown that $\operatorname{rank}(M_2) = 7$ [HK71, Win71] and much more recently, the border rank (see Section 15.4) of M_2 is 7 [Lan06].

4. In quantum computing, a *pure state*, also known as a completely separable state, corresponds to a rank-1 tensor. A quantum state that is not pure is called *entangled.* A natural, but not the most commonly used, measure of the degree of *entanglement* is therefore tensor rank [Bry02], i.e., the minimal number of pure states it can be written as a sum of. For example, the well-known Greenberger–Horne–Zeilinger state [GHZ89] may be regarded as a $2 \times 2 \times 2$ hypermatrix of rank 2:

$$|\mathrm{GHZ}\rangle = \frac{1}{\sqrt{2}}(|0\rangle \otimes |0\rangle \otimes |0\rangle + |1\rangle \otimes |1\rangle \otimes |1\rangle) \in \mathbb{C}^{2\times 2\times 2},$$

while the W state [DVC00] may be regarded as a $2 \times 2 \times 2$ hypermatrix of rank 3:

$$|W\rangle = \frac{1}{\sqrt{3}}(|0\rangle \otimes |0\rangle \otimes |1\rangle + |0\rangle \otimes |1\rangle \otimes |0\rangle + |1\rangle \otimes |0\rangle \otimes |0\rangle) \in \mathbb{C}^{2\times 2\times 2}.$$

15.4 Border Rank

We now discuss a phenomenon that may appear peculiar at first since one does not encounter this for usual matrices or tensors of order 2. As one will see from the following examples, we may get a sequence of 3-hypermatrices of rank not more than 2 converging to a limit that has rank 3, which is somewhat surprising since for matrices, this can never happen. Another way to say this is that the set $\{A \in \mathbb{C}^{m\times n} : \operatorname{rank}(A) \le r\}$ is closed. What we deduce from this example is the same does not hold for hypermatrices, the set $\{A \in \mathbb{C}^{l\times m\times n} : \operatorname{rank}(A) \le r\}$ is not a closed set in general.

Definitions:

The **border rank** of a hypermatrix $A \in \mathbb{C}^{n_1\times\cdots\times n_d}$ is

$$\overline{\operatorname{rank}}(A) = \min\left\{ r : \inf_{\operatorname{rank}(B)\le r} \|A - B\| = 0 \right\},$$

where $\|\cdot\|$ is any norm on hypermatrices (including one obtained by identifying $A \in \mathbb{C}^{n_1\times\cdots\times n_d}$ with $\mathbb{C}^{n_1\cdots n_d}$; see Section 15.8).

Facts:

Facts requiring proof for which no specific reference is given can be found in [BCS96, Chap. 19], [Lan12, Chap. 3], [Lim], and the references therein.

1. For $A \in \mathbb{C}^{n_1\times\cdots\times n_d}$, $\overline{\operatorname{rank}}(A) \le \operatorname{rank}(A)$.
2. For a matrix $A \in \mathbb{C}^{m\times n}$, $\overline{\operatorname{rank}}(A) = \operatorname{rank}(A)$.
3. There exist examples of a sequence of 3-hypermatrices of rank not more than 2 that converges to a limit that has rank 3 [BLR80] (see Examples 1 and 2). In fact, the gap between rank and border rank can be arbitrarily large.
4. Let $A = [A_1 \mid A_2 \mid A_3] \in \mathbb{C}^{n\times n\times 3}$ where A_2 is invertible. Then
$$\overline{\operatorname{rank}}(A) \ge n + \frac{1}{2}\operatorname{rank}(A_1 A_2^{-1} A_3 - A_3 A_2^{-1} A_1).$$
5. Let $A \in \mathbb{C}^{n_1\times\cdots\times n_d}$ and $(X_1, \ldots, X_d) \in \mathrm{GL}(n_1, \ldots, n_d, \mathbb{C})$. Then
$$\overline{\operatorname{rank}}((X_1, \ldots, X_d) \cdot A) = \overline{\operatorname{rank}}(A).$$
6. While border rank is defined here for hypermatrices, the definition of border rank extends to tensors via coordinate representation because of the invariance of rank under change of basis (cf. Fact 15.3.2).

7. Suppose $\operatorname{rank}(T) = r$ and $\overline{\operatorname{rank}}(T) = s$. If $s < r$, then T has no best rank-s approximation.

Examples:

1. [BLR80] The original example of a hypermatrix whose border rank is less than its rank is a $2 \times 2 \times 2$ hypermatrix. In the notation of Section 15.1, if we choose $\mathbf{x}_p = (1,0), \mathbf{y}_p = (0,1) \in \mathbb{C}^2$ for $p = 1, 2, 3$, then

$$A = \begin{bmatrix}1\\0\end{bmatrix} \otimes \begin{bmatrix}1\\0\end{bmatrix} \otimes \begin{bmatrix}0\\1\end{bmatrix} + \begin{bmatrix}1\\0\end{bmatrix} \otimes \begin{bmatrix}0\\1\end{bmatrix} \otimes \begin{bmatrix}1\\0\end{bmatrix} + \begin{bmatrix}0\\1\end{bmatrix} \otimes \begin{bmatrix}1\\0\end{bmatrix} \otimes \begin{bmatrix}1\\0\end{bmatrix} = \left[\begin{array}{cc|cc}0 & 1 & 1 & 0\\ 1 & 0 & 0 & 0\end{array}\right] \in \mathbb{C}^{2\times 2\times 2}$$

and

$$\begin{aligned} A_\varepsilon &= \frac{1}{\varepsilon}\begin{bmatrix}1\\\varepsilon\end{bmatrix} \otimes \begin{bmatrix}1\\\varepsilon\end{bmatrix} \otimes \begin{bmatrix}1\\\varepsilon\end{bmatrix} - \frac{1}{\varepsilon}\begin{bmatrix}1\\0\end{bmatrix} \otimes \begin{bmatrix}1\\0\end{bmatrix} \otimes \begin{bmatrix}1\\0\end{bmatrix} \\ &= \frac{1}{\varepsilon}\left[\begin{array}{cc|cc}1 & \varepsilon & \varepsilon & \varepsilon^2\\ \varepsilon & \varepsilon^2 & \varepsilon^2 & \varepsilon^3\end{array}\right] - \frac{1}{\varepsilon}\left[\begin{array}{cc|cc}1 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\end{array}\right] = \left[\begin{array}{cc|cc}0 & 1 & 1 & \varepsilon\\ 1 & \varepsilon & \varepsilon & \varepsilon^2\end{array}\right] \in \mathbb{C}^{2\times 2\times 2}, \end{aligned}$$

from which it is clear that $\lim_{\varepsilon\to 0} A_\varepsilon = A$. We note here that the hypermatrix A is actually the same hypermatrix that represents the W state in quantum computing (cf. Example 15.3.4).

2. Choose linearly independent pairs of vectors $\mathbf{x}_1, \mathbf{y}_1 \in \mathbb{C}^l$, $\mathbf{x}_2, \mathbf{y}_2 \in \mathbb{C}^m$, $\mathbf{x}_3, \mathbf{y}_3 \in \mathbb{C}^n$ (so $l, m, n \geq 2$ necessarily). Define the 3-hypermatrix,

$$A := \mathbf{x}_1 \otimes \mathbf{x}_2 \otimes \mathbf{y}_3 + \mathbf{x}_1 \otimes \mathbf{y}_2 \otimes \mathbf{x}_3 + \mathbf{y}_1 \otimes \mathbf{x}_2 \otimes \mathbf{x}_3 \in \mathbb{C}^{l\times m\times n},$$

and, for any $\varepsilon \neq 0$, a family of 3-hypermatrices parameterized by ε,

$$A_\varepsilon := \frac{(\mathbf{x}_1 + \varepsilon\mathbf{y}_1) \otimes (\mathbf{x}_2 + \varepsilon\mathbf{y}_2) \otimes (\mathbf{x}_3 + \varepsilon\mathbf{y}_3) - \mathbf{x}_1 \otimes \mathbf{x}_2 \otimes \mathbf{x}_3}{\varepsilon}.$$

Now it is easy to verify that

$$A - A_\varepsilon = \varepsilon(\mathbf{y}_1 \otimes \mathbf{y}_2 \otimes \mathbf{x}_3 + \mathbf{y}_1 \otimes \mathbf{x}_2 \otimes \mathbf{y}_3 + \mathbf{x}_1 \otimes \mathbf{y}_2 \otimes \mathbf{y}_3) \tag{15.20}$$

and so

$$\|A - A_\varepsilon\| = O(\varepsilon)$$

In other words, A can be approximated arbitrarily closely by A_ε. As a result,

$$\lim_{\varepsilon\to 0} A_\varepsilon = A.$$

One may also check that $\operatorname{rank}(A) = 3$ while it is clear that $\operatorname{rank}(A_\varepsilon) \leq 2$. By definition, the border rank of A is not more than 2. In fact, $\overline{\operatorname{rank}}(A) = 2$ because a rank-1 hypermatrix always has border rank equals to 1 and as such the border rank of a hypermatrix whose rank and border rank differ must have border rank at least 2 and rank at least 3.

3. There are various results regarding the border rank of hypermatrices of specific dimensions. If either l, m, or $n = 2$, then a hypermatrix $A = [A_1, A_2] \in \mathbb{C}^{m\times n\times 2}$ may be viewed as a matrix pencil and we may depend on the Kronecker-Weierstraß canonical form to deduce results about rank and border rank.

4. One may define border rank algebraically over arbitrary fields without involving norm by considering expressions like those in Eq. (15.20) modulo ε. We refer the reader to [BCS96, Knu98] for more details on this.

15.5 Generic and Maximal Rank

Unlike tensor rank, border rank, and multilinear rank, the notions of rank discussed in this section apply to the whole space rather than an individual hypermatrix or tensor.

Definitions:

Let F be a field.

The **maximum rank** of $F^{n_1\times\cdots\times n_d}$ is

$$\operatorname{maxrank}_F(n_1,\ldots,n_d) = \max\{\operatorname{rank}(A) : A \in F^{n_1\times\cdots\times n_d}\}.$$

The **generic rank** of $\mathbb{C}^{n_1\times\cdots\times n_d}$ as

$$\operatorname{genrank}_{\mathbb{C}}(n_1,\ldots,n_d) = \max\{\overline{\operatorname{rank}}(A) : A \in \mathbb{C}^{n_1\times\cdots\times n_d}\}.$$

Facts:

Facts requiring proof for which no specific reference is given can be found in [Lan12, Chap. 3].

1. The concepts of maxrank and genrank are uninteresting for matrices (i.e., 2-hypermatrices) since
$$\operatorname{genrank}_{\mathbb{C}}(m,n) = \operatorname{maxrank}_{\mathbb{C}}(m,n) = \max\{m,n\},$$
but for $d > 2$, the exact values of $\operatorname{genrank}_{\mathbb{C}}(l,m,n)$ and $\operatorname{maxrank}_{\mathbb{C}}(l,m,n)$ are mostly unknown.
2. Since $\overline{\operatorname{rank}}(A) \leq \operatorname{rank}(A)$, $\operatorname{genrank}_{\mathbb{C}}(n_1,\ldots,n_d) \leq \operatorname{maxrank}_{\mathbb{C}}(n_1,\ldots,n_d)$.
3. A simple dimension count yields the following lower bound
$$\operatorname{genrank}_{\mathbb{C}}(n_1,\ldots,n_d) \geq \left\lceil \frac{n_1\cdots n_d}{n_1+\cdots+n_d-d+1} \right\rceil.$$
Note that strict inequaltiy can occur when $d > 2$. For example, for $d = 3$,
$$\operatorname{genrank}_{\mathbb{C}}(2,2,2) = 2 \text{ whereas } \operatorname{maxrank}_{\mathbb{C}}(2,2,2) = 3$$
and $\operatorname{genrank}_{\mathbb{C}}(3,3,3) = 5$ [Str83] while $\lceil 3^3/(3\times 3-3+1)\rceil = 4$.
4. The generic rank is a *generic* property in $\mathbb{C}^{n_1\times\cdots\times n_d}$, i.e., every hypermatrix would have rank equal to $\operatorname{genrank}_{\mathbb{C}}(n_1,\ldots,n_d)$ except for those in some proper Zariski-closed subset. In particular, hypermatrices that do not have rank $\operatorname{genrank}_{\mathbb{C}}(n_1,\ldots,n_d)$ are contained in a measure-zero subset of $\mathbb{C}^{n_1\times\cdots\times n_d}$ (with respect to, say, the Lebesgue or Gaussian measure).
5. There is a notion of *typical rank* that is analogous to generic rank for fields that are not algebraically closed.

15.6 Rank-Retaining Decomposition

Matrices have a notion of rank-retaining decomposition, i.e., given $A \in \mathbb{C}^{m\times n}$, there are various ways to write it down as a product of two matrices $A = GH$ where $G \in \mathbb{C}^{m\times r}$ and $H \in \mathbb{C}^{r\times n}$ where $r = \operatorname{rank}(A)$. Examples include the LU, QR, SVD, and others.

There is a rank-retaining decomposition that may be stated in a form that is almost identical to the singular value decomposition of a matrix, with one caveat — the analogue of the singular vectors would in general not be orthogonal (cf. Fact 1). This decomposition is often unique, a result due to Kruskal that depends on the notion of *Kruskal rank*, a concept that has been reinvented multiple times under different names (originally as *girth* in matroid theory [Oxl11], as *krank* in tensor decompositions [SB00], and most recently as *spark* in compressive sensing [DE03]). The term "Kruskal rank" was not coined by Kruskal himself who simply denoted it as k_S. It is an unfortunate nomenclature, since it is not a notion of rank. "Kruskal dimension" would have been more appropriate.

Definitions:

Let V be a vector space, $\mathbf{v}_1, \ldots, \mathbf{v}_n \in V$, and $S = \{\mathbf{v}_1, \ldots, \mathbf{v}_n\}$.

The **Kruskal rank** or **krank** of S, denoted $\operatorname{krank}(S)$ or $\operatorname{krank}(\mathbf{v}_1, \ldots, \mathbf{v}_r)$, is the largest $k \in \mathbb{N}$ so that every k-element subset of S is linearly independent.

The **girth** or **spark** of S is the smallest $s \in \mathbb{N}$ so that there exists an s-element subset of S that is linear dependent.

We say that a decomposition of the form (15.21) is **essentially unique** if given another such decomposition,

$$\sum\nolimits_{p=1}^{r} \alpha_p \mathbf{v}_p^{(1)} \otimes \cdots \otimes \mathbf{v}_p^{(d)} = \sum\nolimits_{p=1}^{r} \beta_p \mathbf{w}_p^{(1)} \otimes \cdots \otimes \mathbf{w}_p^{(d)},$$

we must have (i) the coefficients $\alpha_p = \beta_p$ for all $p = 1, \ldots, r$; and (ii) the factors $\mathbf{v}_p^{(1)}, \ldots, \mathbf{v}_p^{(d)}$ and $\mathbf{w}_p^{(1)}, \ldots, \mathbf{w}_p^{(d)}$ differ at most via unimodulus scaling, i.e.,

$$\mathbf{v}_p^{(1)} = e^{i\theta_{1p}} \mathbf{w}_p^{(1)}, \ldots, \mathbf{v}_p^{(d)} = e^{i\theta_{dp}} \mathbf{w}_p^{(d)}$$

where $\theta_{1p} + \cdots + \theta_{dp} \equiv 0 \bmod 2\pi$, for all $p = 1, \ldots, r$. In the event when successive coefficients are equal, $\sigma_{p-1} > \sigma_p = \sigma_{p+1} = \cdots = \sigma_{p+q} > \sigma_{p+q+1}$, the uniqueness of the factors in (ii) is only up to relabeling of indices $p, \ldots, p+q$.

Facts:

Facts requiring proof for which no specific reference is given can be found in [Lim] and the references therein.

1. Let $A \in \mathbb{C}^{n_1 \times \cdots \times n_d}$. Then A has a rank-retaining decomposition

   $$A = \sum\nolimits_{p=1}^{r} \sigma_p \mathbf{v}_p^{(1)} \otimes \cdots \otimes \mathbf{v}_p^{(d)}, \tag{15.21}$$

   with $r = \operatorname{rank}(A)$ and $\sigma_1, \ldots, \sigma_r \in \mathbb{R}$, which can be chosen to be all positive, and

   $$\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_r,$$

   and $\mathbf{v}_p^{(k)} \in \mathbb{C}^{n_k}$ has unit norm $\|\mathbf{v}_p^{(k)}\|_2 = 1$ all $k = 1, \ldots, d$ and all $p = 1, \ldots, r$.
2. Fact 1 has a coordinate-free counterpart: If $T \in V_1 \otimes \cdots \otimes V_d$, then we may also write

   $$T = \sum\nolimits_{p=1}^{r} \sigma_p \mathbf{v}_p^{(1)} \otimes \cdots \otimes \mathbf{v}_p^{(d)},$$

   where $r = \operatorname{rank}(T)$, $\mathbf{v}_p^{(k)} \in V_k$ are vectors in an abstract $\mathbb{C}$-vector space. Furthermore if the V_k's are all equipped with norms, then $\mathbf{v}_p^{(k)}$ may all be chosen to be unit vectors and σ_p may all be chosen to be positive real numbers. As such, we may rightly call a decomposition of the form (15.21) a *tensor decomposition*, with Fact 1 being the special case when $V_k = \mathbb{C}^{n_k}$.
3. For the special case $d = 2$, the unit-norm vectors $\{\mathbf{v}_1^{(1)}, \ldots, \mathbf{v}_r^{(1)}\}$ and $\{\mathbf{v}_1^{(2)}, \ldots, \mathbf{v}_r^{(2)}\}$ may in fact be chosen to be orthonormal. If we write $U := [\mathbf{v}_1^{(1)}, \ldots, \mathbf{v}_r^{(1)}] \in \mathbb{C}^{n_1 \times r}$ and $V := [\mathbf{v}_1^{(2)}, \ldots, \mathbf{v}_r^{(2)}] \in \mathbb{C}^{n_2 \times r}$, Fact 1 yields the singular value decomposition

$A = U\Sigma V^*$. Hence, Fact 1 may be viewed as a generalization of matrix singular value decomposition. The one thing that we lost in going from order $d = 2$ to $d \geq 3$ is the orthonormality of the "singular vectors" $\mathbf{v}_1^{(k)}, \dots, \mathbf{v}_r^{(k)}$. In fact, this is entirely to be expected because when $d \geq 2$, it is often the case that $\operatorname{rank}(A) > \max\{n_1, \dots, n_d\}$ and so it is impossible for $\mathbf{v}_1^{(k)}, \dots, \mathbf{v}_r^{(k)}$ to be orthonormal or even linearly independent.

4. A decomposition of the form in Fact 1 is in general not unique if we do not impose orthogonality on the factors $\{\mathbf{v}_p^{(k)} : p = 1, \dots, r\}$ but this is easily seen to be impossible via a simple dimension count: Suppose $n_1 = \cdots = n_d = n$, an orthonormal collection of n vectors has dimension $n(n-1)/2$ and so the right-hand side of Eq. (15.21) has dimension at most $n + dn(n-1)/2$ but the left-hand side has dimension n^d. Fortunately, there is an amazing result due to Kruskal that guarantees a slightly weaker form of uniqueness of Eq. (15.21) for $d \geq 3$ without requiring orthogonality.
5. It is clear that girth (= spark) and krank are one and the same notion, related by $\operatorname{girth}(S) = \operatorname{krank}(S) + 1$.
6. The krank of $\mathbf{v}_1, \dots, \mathbf{v}_r \in V$ is $\mathrm{GL}(V)$-invariant: If $X \in \mathrm{GL}(V)$, then
$$\operatorname{krank}(X\mathbf{v}_1, \dots, X\mathbf{v}_r) = \operatorname{krank}(\mathbf{v}_1, \dots, \mathbf{v}_r).$$
7. $\operatorname{krank}(\mathbf{v}_1, \dots, \mathbf{v}_r) \leq \dim \operatorname{span}\{\mathbf{v}_1, \dots, \mathbf{v}_r\}$.
8. [Kru77] Let $A \in \mathbb{C}^{l \times m \times n}$. Then a decomposition of the form
$$A = \sum\nolimits_{p=1}^{r} \sigma_p \mathbf{u}_p \otimes \mathbf{v}_p \otimes \mathbf{w}_p$$
is both rank-retaining, i.e., $r = \operatorname{rank}(A)$, and essentially unique if the following combinatorial condition is met:
$$\operatorname{krank}(\mathbf{u}_1, \dots, \mathbf{u}_r) + \operatorname{krank}(\mathbf{v}_1, \dots, \mathbf{v}_r) + \operatorname{krank}(\mathbf{w}_1, \dots, \mathbf{w}_r) \geq 2r + 2.$$
This is the *Kruskal uniqueness theorem.*
9. [SB00] Fact 8 has been generalized to arbitrary order $d \geq 3$. Let $A \in \mathbb{C}^{n_1 \times \cdots \times n_d}$ where $d \geq 3$. Then a decomposition of the form
$$A = \sum\nolimits_{p=1}^{r} \sigma_p \mathbf{v}_p^{(1)} \otimes \cdots \otimes \mathbf{v}_p^{(d)}$$
is both rank-retaining, i.e., $r = \operatorname{rank} A$, and essentially unique if the following condition is satisfied:
$$\sum\nolimits_{k=1}^{d} \operatorname{krank}(\mathbf{v}_1^{(k)}, \dots, \mathbf{v}_r^{(k)}) \geq 2r + d - 1. \tag{15.22}$$
10. A result analogous to the Kruskal uniqueness theorem (Fact 8) does not hold for $d = 2$, since a decomposition of a matrix $A \in \mathbb{C}^{n \times n}$ can be written in infinitely many different ways $A = UV^\top = (UX^{-1})(XV)$ for any $X \in \mathrm{GL}(n, \mathbb{C})$. This is not surprising since Eq. (15.22) can never be true for $d = 2$ because of Fact 7.
11. [Der13] For $d \geq 3$, the condition (15.22) is sharp in the sense that the right-hand side cannot be further reduced.
12. One may also write the decomposition in Fact 1 in the form of multilinear matrix multiplication,
$$A = \sum\nolimits_{i=1}^{r} \lambda_i \mathbf{x}_i \otimes \mathbf{y}_i \otimes \mathbf{z}_i = (X, Y, Z) \cdot \Lambda, \quad a_{\alpha\beta\gamma} = \sum\nolimits_{i=1}^{r} \lambda_i x_{\alpha i} y_{\beta i} z_{\gamma i},$$
of three matrices $X = [\mathbf{x}_1, \dots, \mathbf{x}_r] \in \mathbb{C}^{l \times r}$, $Y = [\mathbf{y}_1, \dots, \mathbf{y}_r] \in \mathbb{C}^{m \times r}$, $Z = [\mathbf{z}_1, \dots, \mathbf{z}_r] \in \mathbb{C}^{n \times r}$ with a diagonal hypermatrix $\Lambda = \operatorname{diag}[\lambda_1, \dots, \lambda_r] \in \mathbb{C}^{r \times r \times r}$, i.e.,
$$\lambda_{ijk} = \begin{cases} \lambda_i & i = j = k, \\ 0 & \text{otherwise.} \end{cases}$$

Note however that this is not a multilinear rank-retaining decomposition in the sense of the next section, since $\mu\,\mathrm{rank}(A) \neq (r,r,r)$ in general.

15.7 Multilinear Rank

For a matrix $A = [a_{ij}] \in F^{m\times n}$ we have a nice equality between three numerical invariants associated with A:

$$\begin{aligned}\mathrm{rank}(A) &= \dim \mathrm{span}_F\{A_{\bullet 1},\dots,A_{\bullet n}\} && (15.23)\\ &= \dim \mathrm{span}_F\{A_{1\bullet},\dots,A_{m\bullet}\} && (15.24)\\ &= \min\{r : A = \mathbf{x}_1\mathbf{y}_1^\top + \cdots + \mathbf{x}_r\mathbf{y}_r^\top\}. && (15.25)\end{aligned}$$

Here we let $A_{i\bullet} = [a_{i1},\dots,a_{im}]^T \in F^m$ and $A_{\bullet j} = [a_{1j},\dots,a_{nj}]^T \in F^n$ denote the ith row and jth column vectors of A. The numbers in Eqs. (15.24) and (15.23) are the row and column ranks of A. Their equality is a standard fact in linear algebra and the common value is called the rank of A. The number in Eq. (15.25) is also easily seen to be equal to rank(A).

For a hypermatrix $A = [a_{ijk}] \in F^{l\times m\times n}$, one may also define analogous numbers. However, we generally have four distinct numbers, with the first three, called *multilinear rank* associated with the three different ways to slice A, and the analog of Eq. (15.25) being the tensor rank of A (cf. Section 15.3). The multilinear rank is essentially matrix rank and so inherits many of the latter's properties, so we do not see the sort of anomalies discussed in Sections 15.4 and 15.5.

Like the tensor rank, the notion of multilinear rank was due to Hitchcock [Hit27b], as a special case (2-plex rank) of his *multiplex rank*.

Definitions:

For a hypermatrix $A = [a_{ijk}] \in F^{l\times m\times n}$,

$$\begin{aligned}r_1 &= \dim \mathrm{span}_F\{A_{1\bullet\bullet},\dots,A_{l\bullet\bullet}\}, && (15.26)\\ r_2 &= \dim \mathrm{span}_F\{A_{\bullet 1\bullet},\dots,A_{\bullet m\bullet}\}, && (15.27)\\ r_3 &= \dim \mathrm{span}_F\{A_{\bullet\bullet 1},\dots,A_{\bullet\bullet n}\}. && (15.28)\end{aligned}$$

Here $A_{i\bullet\bullet} = [a_{ijk}]_{j,k=1}^{m,n} \in F^{m\times n}$, $A_{\bullet j\bullet} = [a_{ijk}]_{i,k=1}^{l,n} \in F^{l\times n}$, $A_{\bullet\bullet k} = [a_{ijk}]_{i,j=1}^{l,m} \in F^{l\times m}$. The **multilinear rank** of $A \in F^{l\times m\times n}$ is $\mu\,\mathrm{rank}(A) := (r_1, r_2, r_3)$, with r_1, r_2, r_3 defined in Eqs. (15.26), (15.27), and (15.28). The definition for a d-hypermatrix with $d > 3$ is analogous.

The k**th flattening map** on $F^{n_1\times\cdots\times n_d}$ is the function

$$\flat_k : F^{n_1\times\cdots\times n_d} \to F^{n_k\times(n_1\dots\widehat{n}_k\dots n_d)}$$

defined by

$$(\flat_k(A))_{ij} = (A)_{s_k(i,j)}$$

where $s_k(i,j)$ is the jth element in lexicographic order in the subset of $\langle n_1\rangle\times\cdots\times\langle n_d\rangle$ consisting of elements that have kth coordinate equal to i, and by convention a caret over any entry of a d-tuple means that the respective entry is omitted. See Example 1.

The **multilinear kernels** or **nullspaces** of $T \in U\otimes V\otimes W$ are

$$\begin{aligned}\ker_1(T) &= \{\mathbf{u}\in U : T(\mathbf{u},\mathbf{v},\mathbf{w}) = 0 \text{ for all } \mathbf{v}\in V, \mathbf{w}\in W\},\\ \ker_2(T) &= \{\mathbf{v}\in V : T(\mathbf{u},\mathbf{v},\mathbf{w}) = 0 \text{ for all } \mathbf{u}\in U, \mathbf{w}\in W\},\\ \ker_3(T) &= \{\mathbf{w}\in W : T(\mathbf{u},\mathbf{v},\mathbf{w}) = 0 \text{ for all } \mathbf{u}\in U, \mathbf{v}\in V\}.\end{aligned}$$

The **multilinear images** or **range spaces** of $T \in U \otimes V \otimes W$ are

$$\begin{aligned}
\operatorname{im}_1(T) &= \{A \in V \otimes W : A(\mathbf{v}, \mathbf{w}) = T(\mathbf{u}_0, \mathbf{v}, \mathbf{w}) \text{ for some } \mathbf{u}_0 \in U\},\\
\operatorname{im}_2(T) &= \{B \in U \otimes W : B(\mathbf{u}, \mathbf{w}) = T(\mathbf{u}, \mathbf{v}_0, \mathbf{w}) \text{ for some } \mathbf{v}_0 \in V\},\\
\operatorname{im}_3(T) &= \{C \in U \otimes V : C(\mathbf{u}, \mathbf{v}) = T(\mathbf{u}, \mathbf{v}, \mathbf{w}_0) \text{ for some } \mathbf{w}_0 \in W\}.
\end{aligned}$$

The **multilinear nullity** of $T \in U \otimes V \otimes W$ is

$$\mu\,\operatorname{nullity}(T) = (\dim \ker_1(T), \dim \ker_2(T), \dim \ker_3(T)).$$

The **multilinear rank** of $T \in U \otimes V \otimes W$ is

$$\mu\,\operatorname{rank}(T) = (\dim \operatorname{im}_1(T), \dim \operatorname{im}_2(T), \dim \operatorname{im}_3(T)).$$

Facts:

Facts requiring proof for which no specific reference is given can be found in [Lan12, Chap. 2] as well as [Lim] and the references therein.

1. For $A \in F^{l\times m\times n}$, the multilinear rank $\mu\,\operatorname{rank}(A) = (r_1, r_2, r_3)$ is given by

$$r_1 = \operatorname{rank}(\flat_1(A)), \quad r_2 = \operatorname{rank}(\flat_2(A)), \quad r_3 = \operatorname{rank}(\flat_3(A)),$$

where rank here is of course the usual matrix rank of the matrices $\flat_1(A), \flat_2(A), \flat_3(A)$.

2. Let $A \in F^{l\times m\times n}$. For any $X \in \operatorname{GL}(l, F), Y \in \operatorname{GL}(m, F), Z \in \operatorname{GL}(n, F)$,

$$\mu\,\operatorname{rank}((X, Y, Z) \cdot A) = \mu\,\operatorname{rank}(A).$$

3. Let $T \in V_1 \otimes \cdots \otimes V_d$. For bases $\mathcal{B}_k$ for $V_k, k = 1, \dots, d$,

$$\mu\,\operatorname{rank}([T]_{\mathcal{B}_1,\dots,\mathcal{B}_d}) = \mu\,\operatorname{rank}(T).$$

4. Let $T \in U \otimes V \otimes W$. The *rank-nullity theorem* for multilinear rank is:

$$\mu\,\operatorname{nullity}(T) + \mu\,\operatorname{rank}(T) = (\dim U, \dim V, \dim W).$$

5. If $A \in F^{l\times m\times n}$ has $\mu\,\operatorname{rank}(A) = (p, q, r)$, then there exist matrices $X \in F^{l\times p}, Y \in F^{m\times q}, Z \in F^{n\times r}$ of full column rank and $C \in \mathbb{C}^{p\times q\times r}$ such that

$$A = (X, Y, Z) \cdot C,$$

i.e., A may be expressed as a multilinear matrix product of C by X, Y, Z, defined according to Eq. (15.1). We shall call this a multilinear rank-retaining decomposition or just *multilinear decomposition* for short.

6. One may also write Fact 5 in the form of a multiply indexed sum of decomposable hypermatrices

$$A = \sum\nolimits_{i,j,k=1}^{p,q,r} c_{ijk} \mathbf{x}_i \otimes \mathbf{y}_j \otimes \mathbf{z}_k$$

where $\mathbf{x}_i \in F^l, \mathbf{y}_j \in F^m, \mathbf{z}_k \in F^n$ are the respective columns of the matrices X, Y, Z.

7. Let $A \in \mathbb{C}^{l\times m\times n}$ and $\mu\,\operatorname{rank}(A) = (p, q, r)$. There exist $L_1 \in \mathbb{C}^{l\times p}$, $L_2 \in \mathbb{C}^{m\times q}$, $L_3 \in \mathbb{C}^{n\times r}$ unit lower triangular and $U \in \mathbb{C}^{p\times q\times r}$ such that

$$A = (L_1, L_2, L_3) \cdot U.$$

This may be viewed as the analogues of the LU decomposition for hypermatrices with respect to the notion of multilinear rank.

8. Let $A \in \mathbb{C}^{l\times m\times n}$ and $\mu\operatorname{rank}(A) = (p, q, r)$. There exist $Q_1 \in \mathbb{C}^{l\times p}$, $Q_2 \in \mathbb{C}^{m\times q}$, $Q_3 \in \mathbb{C}^{n\times r}$ with orthonormal columns and $R \in \mathbb{C}^{p\times q\times r}$ such that
$$A = (Q_1, Q_2, Q_3) \cdot R.$$
This may be viewed as the analogues of the QR decomposition for hypermatrices with respect to the notion of multilinear rank.
9. The LU and QR decompositions in Facts 7 and 8 are among the few things that can be computed for hypermatrices, primarily because multilinear rank is essentially a matrix notion. For example, one may apply usual Gaussian elimination or Householder/Givens QR to the flattenings of $A \in F^{l\times m\times n}$ successively, reducing all computations to standard matrix computations.

Examples:

1. Let
$$A = \left[\begin{array}{ccc|ccc} a_{111} & a_{121} & a_{131} & a_{112} & a_{122} & a_{132} \\ a_{211} & a_{221} & a_{231} & a_{212} & a_{222} & a_{232} \\ a_{311} & a_{321} & a_{331} & a_{312} & a_{322} & a_{332} \\ a_{411} & a_{421} & a_{431} & a_{412} & a_{422} & a_{432} \end{array}\right] \in \mathbb{C}^{4\times 3\times 2},$$
then
$$\flat_1(A) = \begin{bmatrix} a_{111} & a_{112} & a_{121} & a_{122} & a_{131} & a_{132} \\ a_{211} & a_{212} & a_{221} & a_{222} & a_{231} & a_{232} \\ a_{311} & a_{312} & a_{321} & a_{322} & a_{331} & a_{332} \\ a_{411} & a_{412} & a_{421} & a_{422} & a_{431} & a_{432} \end{bmatrix} \in \mathbb{C}^{4\times 6},$$
$$\flat_2(A) = \begin{bmatrix} a_{111} & a_{112} & a_{211} & a_{212} & a_{311} & a_{312} & a_{411} & a_{412} \\ a_{121} & a_{122} & a_{221} & a_{222} & a_{321} & a_{322} & a_{421} & a_{422} \\ a_{131} & a_{132} & a_{231} & a_{232} & a_{331} & a_{332} & a_{431} & a_{432} \end{bmatrix} \in \mathbb{C}^{3\times 8},$$
$$\flat_3(A) = \begin{bmatrix} a_{111} & a_{121} & a_{131} & a_{211} & a_{221} & a_{231} & a_{311} & a_{321} & a_{331} & a_{411} & a_{421} & a_{431} \\ a_{112} & a_{122} & a_{132} & a_{212} & a_{222} & a_{232} & a_{312} & a_{322} & a_{332} & a_{412} & a_{422} & a_{432} \end{bmatrix} \in \mathbb{C}^{2\times 12}.$$
2. Note that if we had a bilinear form represented by a matrix $M \in \mathbb{C}^{m\times n}$, the analogues of these subspaces would be the four fundamental subspaces of the matrix: $\ker_1(M) = \ker(M)$, $\operatorname{im}_1(M) = \operatorname{im}(M)$, $\ker_2(M) = \ker(M^T)$, $\operatorname{im}_2(M) = \operatorname{im}(M^T)$. The rank-nullity theorem reduces to the usual one:
$$(\operatorname{nullity}(M) + \operatorname{rank}(M), \operatorname{nullity}(M^T) + \operatorname{rank}(M^T)) = (n, m).$$

15.8 Norms

In this section we will discuss the Hölder, induced, and nuclear norms of hypermatrices. When discussing multiple variety of norms, one has to introduce different notation to distinguish them and here we follow essentially the notation and terminology for matrix norms in Chapter 24, adapted as needed for hypermatrices. For the induced and nuclear norms, we assume $d = 3$ to avoid notational clutter.

Definitions:

For $A = [a_{j_1\cdots j_d}]_{j_1,\ldots,j_d=1}^{n_1,\ldots,n_d} \in \mathbb{C}^{n_1\times\cdots\times n_d}$ and $p \in [1, \infty]$, the **Hölder p-norm** is defined by
$$\|A\|_{H,p} := \left(\sum\nolimits_{j_1,\ldots,j_d=1}^{n_1,\ldots,n_d} |a_{j_1\cdots j_d}|^p\right)^{1/p}, \tag{15.29}$$

with the usual alternate definition for $p = \infty$,

$$\|A\|_{H,\infty} := \max\{|a_{j_1\cdots j_d}| : j_1 = 1, \ldots, n_1; \ldots; j_d = 1, \ldots, n_d\}.$$

$\|A\|_{H,2}$ is often denoted $\|A\|_F$ and called the **Frobenius norm** or **Hilbert–Schmidt norm** of the hypermatrix $A \in \mathbb{C}^{n_1\times\cdots\times n_d}$.

For hypermatrices, the **induced norm**, **natural**, or **operator norm** is defined for $p, q, r \in [1, \infty]$, by the quotient

$$\|A\|_{p,q,r} := \max_{\mathbf{x},\mathbf{y},\mathbf{z}\neq\mathbf{0}} \frac{|A(\mathbf{x}, \mathbf{y}, \mathbf{z})|}{\|\mathbf{x}\|_p\|\mathbf{y}\|_q\|\mathbf{z}\|_r} \tag{15.30}$$

where

$$A(\mathbf{x}, \mathbf{y}, \mathbf{z}) = \sum\nolimits_{i,j,k=1}^{l,m,n} a_{ijk}x_iy_jz_{j_k}.$$

The special case $p = q = r = 2$, i.e., $\|\cdot\|_{2,2,2}$ is the **spectral norm**.

Let $A \in \mathbb{C}^{l\times m\times n}$. The **nuclear norm** or **Schatten 1-norm** of A is defined as

$$\|A\|_{S,1} := \min\Big\{\sum\nolimits_{i=1}^{r}|\lambda_i| : A = \sum\nolimits_{i=1}^{r} \lambda_i\mathbf{u}_i \otimes \mathbf{v}_i \otimes \mathbf{w}_i, \\ \|\mathbf{u}_i\|_2 = \|\mathbf{v}_i\|_2 = \|\mathbf{w}_i\|_2 = 1,\ r \in \mathbb{N}\Big\}. \tag{15.31}$$

For hypermatrices $A \in \mathbb{C}^{n_1\times\cdots\times n_d}$ of arbitrary order, use the obvious generalizations, and of course for $p = \infty$, replace the sum by $\max\{|\lambda_1|, \ldots, |\lambda_r|\}$.

The inner product on $\mathbb{C}^{n_1\times\cdots\times n_d}$ obtained from the dot product on $\mathbb{C}^{n_1\cdots n_d}$ by viewing hypermatrices as complex vectors of dimension $n_1\cdots n_d$, the dot product will be denoted by

$$\langle A, B\rangle := \sum\nolimits_{j_1,\ldots,j_d=1}^{n_1,\ldots,n_d} a_{j_1\cdots j_d}\bar{b}_{j_1\cdots j_d}. \tag{15.32}$$

Facts:

Facts requiring proof for which no specific reference is given can be found in [DF93, Chap. I] as well as [Lim] and the references therein.

1. The hypermatrix Hölder p-norm $\|A\|_{H,p}$ of $A \in \mathbb{C}^{n_1\times\cdots\times n_d}$ is the (vector Hölder) p-norm of A when regarded as a vector of dimension $n_1\cdots n_d$ (see Section 50.1).
2. The Hölder p-norm has the property of being multiplicative on rank-1 hypermatrices in the following sense:

   $$\|\mathbf{u}\otimes\mathbf{v}\otimes\cdots\otimes\mathbf{z}\|_{H,p} = \|\mathbf{u}\|_p\|\mathbf{v}\|_p\cdots\|\mathbf{z}\|_p,$$

   where $\mathbf{u} \in \mathbb{C}^{n_1}, \mathbf{v} \in \mathbb{C}^{n_2}, \ldots, \mathbf{z} \in \mathbb{C}^{n_d}$ and the norms on these are the usual p-norms on vectors.
3. The Frobenius norm is the norm (length) in the inner product space $\mathbb{C}^{n_1\times\cdots\times n_d}$ with Eq. (15.32).
4. The inner product (15.32) (and thus the Frobenius norm) is invariant under multilinear matrix multiplication by unitary matrices,

   $$\langle(Q_1, \ldots, Q_d)\cdot A, (Q_1, \ldots, Q_d)\cdot B\rangle = \langle A, B\rangle, \quad \|(Q_1, \ldots, Q_d)\cdot A\|_F = \|A\|_F$$

   for any $Q_1 \in \mathrm{U}(n_1), \ldots, Q_d \in \mathrm{U}(n_d)$.
5. The inner product (15.32) satisfies a Cauchy-Schwarz inequality

   $$|\langle A, B\rangle| \le \|A\|_F\|B\|_F,$$

and more generally a Hölder inequality

$$|\langle A, B\rangle| \leq \|A\|_{H,p}\|B\|_{H,q}, \quad \frac{1}{p}+\frac{1}{q}=1, \quad p,q\in[1,\infty].$$

6. The induced (p,q,r)-norm is a norm on $\mathbb{C}^{l\times m\times n}$ (with *norm* as defined in Section 50.1).
7. Alternate expressions for the induced norms include

$$\begin{aligned}\|A\|_{p,q,r} &= \max\{|A(\mathbf{u},\mathbf{v},\mathbf{w})| : \|\mathbf{u}\|_p=\|\mathbf{v}\|_q=\|\mathbf{w}\|_r=1\}\\ &= \max\{|A(\mathbf{x},\mathbf{y},\mathbf{z})| : \|\mathbf{x}\|_p\leq 1,\ \|\mathbf{y}\|_q\leq 1,\ \|\mathbf{z}\|_r\leq 1\}.\end{aligned}$$

8. The induced norm is multiplicative on rank-1 hypermatrices

$$\|\mathbf{u}\otimes\mathbf{v}\otimes\mathbf{w}\|_{p,q,r}=\|\mathbf{u}\|_p\|\mathbf{v}\|_q\|\mathbf{w}\|_r$$

for $\mathbf{u}\in\mathbb{C}^l, \mathbf{v}\in\mathbb{C}^m, \mathbf{w}\in\mathbb{C}^n$.

9. For square matrices $A\in\mathbb{C}^{n\times n}$ and $\frac{1}{p}+\frac{1}{q}=1$,

$$\|A\|_{p,q}=\max_{\mathbf{x},\mathbf{y}\neq\mathbf{0}}\frac{|A(\mathbf{x},\mathbf{y})|}{\|\mathbf{x}\|_p\|\mathbf{y}\|_q}=\max_{\mathbf{x},\mathbf{y}\neq\mathbf{0}}\frac{|\mathbf{x}^TA\mathbf{y}|}{\|\mathbf{x}\|_p\|\mathbf{y}\|_q}=\max_{\mathbf{x}\neq\mathbf{0}}\frac{\|A\mathbf{x}\|_q}{\|\mathbf{x}\|_p},$$

the matrix (p,q)-norm.

10. The spectral norm is invariant under mutilinear matrix multiplication

$$\|(Q_1,\dots,Q_d)\cdot A\|_{2,\dots,2}=\|A\|_{2,\dots,2}$$

for any $Q_1\in \mathrm{U}(n_1),\dots,Q_d\in\mathrm{U}(n_d)$.

11. When $d=2$, the nuclear norm defined above reduces to the nuclear norm (i.e., Schatten 1-norm) of a matrix $A\in\mathbb{C}^{m\times n}$ defined more commonly by

$$\|A\|_{S,1}=\sum\nolimits_{i=1}^{\max\{m,n\}}\sigma_i(A).$$

12. [DF93] The nuclear norm defines a norm on $\mathbb{C}^{n_1\times\cdots\times n_d}$ (with *norm* as defined in Section 50.1).
13. The nuclear norm is invariant under mutilinear unitary matrix multiplication, i.e.,

$$\|(Q_1,\dots,Q_d)\cdot A\|_{S,1}=\|A\|_{S,1}$$

for any $Q_1\in \mathrm{U}(n_1),\dots,Q_d\in\mathrm{U}(n_d)$.

14. The nuclear norm and the spectral norm are dual norms to each other, i.e.,

$$\begin{aligned}\|A\|_{S,1}&=\max\{|\langle A,B\rangle| : \|B\|_{2,\dots,2}=1\},\\ \|A\|_{2,\dots,2}&=\max\{|\langle A,B\rangle| : \|B\|_{S,1}=1\}.\end{aligned}$$

15. Since $\mathbb{C}^{n_1\times\cdots\times n_d}$ is finite dimensional, all norms are necessarily equivalent (see Section 50.1). Given that all norms induce the same topology, questions involving convergence of sequences of hypermatrices, whether a set of hypermatrices is closed, etc., are independent of the choice of norms.

Examples:

1. [Der13a] Let T_n be the matrix multiplication tensor in Eq. (15.19). Then $\|T_n\|_F=n^{3/2}$, $\|T_n\|_{S,1}=n^3$, and $\|T_n\|_{2,2,2}=1$.

15.9 Hyperdeterminants

There are two ways to extend the determinant of a matrix to hypermatrices of higher order. One is to simply extend the usual expression of an $n \times n$ matrix determinant as a sum of $n!$ monomials in the entries of the matrix, which we will call the *combinatorial hyperdeterminant*, and the other, which we will call the *geometric hyperdeterminant*, is by using the characterization that a matrix has $\det A = 0$ if and only if $A\mathbf{x} = 0$ has nonzero solutions. Both approaches were proposed by Cayley [Cay49, Cay45], who also gave the explicit expression of a $2 \times 2 \times 2$ geometric hyperdeterminant. Gelfand, Kapranov, and Zelevinsky [GKZ94, GKZ92] have a vast generalization of Cayley's result describing the dimensions of hypermatrices for which geometric hyperdeterminants exist.

Definitions:

The **combinatorial hyperdeterminant** of a cubical d-hypermatrix $A = [a_{i_1 i_2 \cdots i_d}] \in F^{n\times\cdots\times n}$ is defined as

$$\det(A) = \frac{1}{n!} \sum\nolimits_{\pi_1,\ldots,\pi_d \in S_n} \operatorname{sgn}\pi_1 \cdots \operatorname{sgn}\pi_d \prod_{i=1}^{n} a_{\pi_1(i)\cdots\pi_d(i)}. \tag{15.33}$$

If it exists for a given set of dimensions $(n_1, \ldots, n_d)$, a **geometric hyperdeterminant** or **hyperdeterminant** $\mathrm{Det}_{n_1,\ldots,n_d}(A)$ of $A \in \mathbb{C}^{n_1\times\cdots\times n_d}$ is a homogeneous polynomial in the entries of A such that $\mathrm{Det}_{n_1,\ldots,n_d}(A) = 0$ if and only if the system of multilinear equations $\nabla A(\mathbf{x}_1, \ldots, \mathbf{x}_d) = 0$ has a nontrivial solution, i.e., $\mathbf{x}_1, \ldots, \mathbf{x}_d$ all nonzero. Here $\nabla A(\mathbf{x}_1, \ldots, \mathbf{x}_d)$ is the gradient of $A(\mathbf{x}_1, \ldots, \mathbf{x}_d)$ viewed as a function of the coordinates of the vector variables $\mathbf{x}_1, \ldots, \mathbf{x}_d$ (see Preliminaries for the definition of gradient). See Fact 4 for conditions that describe the $n_1, \ldots, n_d$ for which $\mathrm{Det}_{n_1,\ldots,n_d}$ exists.

Facts:

Facts requiring proof for which no specific reference is given may be found in [GKZ94, Chap. 13].

1. For odd order d, the combinatorial hyperdeterminant of a cubical d-hypermatrix is identically zero.
2. For even order d, the combinatorial hyperdeterminant of a cubical d-hypermatrix $A = [a_{i_1 i_2 \cdots i_d}]$ is

$$\det(A) = \sum\nolimits_{\pi_2,\ldots,\pi_d \in S_n} \operatorname{sgn}(\pi_2 \cdots \pi_d) \prod_{i=1}^{n} a_{i\pi_2(i)\cdots\pi_d(i)}.$$

   For $d = 2$, this reduces to the usual expression for the determinant of an $n \times n$ matrix.
3. Taking the π-transpose of an order d-hypermatrix $A \in F^{n\times\cdots\times n}$ leaves the combinatorial hyperdetermiant invariant, i.e., $\det A^{\pi} = \det A$ for and $\pi \in S_d$.
4. (Gelfand–Kapranov–Zelevinsky) A geometric hyperdeterminant exists for $\mathbb{C}^{n_1\times\cdots\times n_d}$ if and only if for all $k = 1, \ldots, d$, the following *dimension condition* is satisfied:

$$n_k - 1 \le \sum\nolimits_{j\ne k} (n_j - 1).$$

5. When the dimension condition in Fact 4 is met, a geometric hyperdeterminant $\mathrm{Det}_{n_1,\ldots,n_d}(A)$ is a multivariate homogeneous polynomial in the entries of A that is unique up to a scalar multiple, and can be scaled to have integer coefficients with greatest common divisor one (the latter is referred to as *the* geometric hyperdeterminant and is unique up to ±1 multiple).

6. The geometric hyperdeterminant exists for all cubical hypermatrices (and by definition is nontrivial when it exists, including for odd order cubical hypermatrices). The geometric hyperdeterminant also exists for some non-cubical hypermatrices (see Fact 3).
7. For $\mathbb{C}^{m\times n}$, the dimension condition in Fact 4 is $m \le n$ and $n \le m$, which may be viewed as a reason why matrix determinants are only defined for square matrices.
8. It is in general nontrivial to find an explicit expression for $\operatorname{Det}_{n_1,\dots,n_d}(A)$. While systematic methods for finding it exists, notably one due to Schläfli [GKZ94], an expression may nonetheless contain a large number of terms when expressed as a sum of monomials. For example, $\operatorname{Det}_{2,2,2,2}(A)$ has more than 2.8 million monomial terms [GHS08] even though a hypermatrix $A \in \mathbb{C}^{2\times 2\times 2\times 2}$ has only 16 entries.
9. Unlike rank and border rank (cf. Facts 15.3.2 and 15.4.5), the geometric hyperdeterminant is not invariant under multilinear matrix multiplication by nonsingular matrices (which is expected since ordinary matrix determinant is not invariant under left and right multiplications by nonsingular matrices either). However, it is *relatively invariant* in the following sense [GKZ94].

   Let $n_1, \dots, n_d$ satisfy the dimension condition in Fact 4. Then for any $A \in \mathbb{C}^{n_1\times\cdots\times n_d}$ and any $X_1 \in \mathrm{GL}(n_1,\mathbb{C}), \dots, X_d \in \mathrm{GL}(n_d,\mathbb{C})$,

   $$\operatorname{Det}_{n_1,\dots,n_d}((X_1,\dots,X_d)\cdot A) = \det(X_1)^{m/n_1}\cdots\det(X_d)^{m/n_d}\operatorname{Det}_{n_1,\dots,n_d}(A) \quad (15.34)$$

   where m is the degree of $\operatorname{Det}_{n_1,\dots,n_d}$. Hence for $X_1 \in \mathrm{SL}(n_1,\mathbb{C}), \dots, X_d \in \mathrm{SL}(n_d,\mathbb{C})$, we get

   $$\operatorname{Det}_{n_1,\dots,n_d}((X_1,\dots,X_d)\cdot A) = \operatorname{Det}_{n_1,\dots,n_d}(A).$$
10. A consequence of Fact 9 is the properties of the usual matrix determinant under row/column interchanges, addition of a scalar multiple of row/column to another, etc., are also true for the hyperdeterminant. For notational convenience, we shall just state the following corollary for a 3-hypermatrix although it is true in general for any d-hypermatrix [GKZ94]. We use the notation in Example 15.1.3 where $A_1, \dots, A_n$ denote the slices of the 3-hypermatrix A, analogues of rows or columns of a matrix. Let l, m, n satisfy the dimension condition in Fact 4 and let $A = [A_1|\dots|A_n] \in \mathbb{C}^{l\times m\times n}$. Then
    (a) interchanging two slices leaves the hyperdeterminant invariant up to sign:

    $$\operatorname{Det}_{l,m,n}([A_1|...|A_i|...|A_j|...|A_n]) = \pm\operatorname{Det}_{l,m,n}([A_1|...|A_j|...|A_i|...|A_n]);$$

    (b) adding a scalar multiple of a slice to another leaves the hyperdeterminant invariant:

    $$\operatorname{Det}_{l,m,n}([A_1|...|A_i|...|A_j|...|A_n]) = \operatorname{Det}_{l,m,n}([A_1|...|A_i + \alpha A_j|...|A_j|...|A_n])$$

    for any $\alpha \in \mathbb{C}$;

    (c) having two proportional slices implies that the hyperdetermiant vanishes:

    $$\operatorname{Det}_{l,m,n}([A_1|...|A_i|...|\alpha A_i|...|A_n]) = 0 \qquad \text{for any } \alpha \in \mathbb{C};$$

    (d) taking π-transpose leaves the hyperdetermiant invariant

    $$\operatorname{Det}_{l,m,n}(A^\pi) = \operatorname{Det}_{l,m,n}(A) \qquad \text{for any } \pi \in S_3.$$

    In particular, the last property implies that the other three properties hold for slices of A in any other fixed index.
11. $\operatorname{Det}_{n_1,\dots,n_d}(A) = 0$ if and only if 0 is a singular value of A.

Examples:

1. For $A = [a_{ijk\ell}] \in F^{2\times 2\times 2\times 2}$, the combinatorial hyperdeterminant of A is

$$\begin{aligned}\det A = a_{1111}a_{2222} - a_{1112}a_{2221} - a_{1121}a_{2212} + a_{1122}a_{2211} \\ - a_{1211}a_{2122} + a_{1122}a_{2211} + a_{1221}a_{2112} + a_{1212}a_{2121}.\end{aligned}$$

   This is immediate from Fact 2, or by applying the definition (15.33) and simplifying.
2. [Cay45] The geometric hyperdeterminant of $A = [A_1|A_2] = [a_{ijk}] \in \mathbb{C}^{2\times 2\times 2}$ (where A_1 and A_2 slices of A, cf. Section 15.1) is

$$\begin{aligned}\mathrm{Det}_{2,2,2}(A) &= \frac{1}{4}[\det(A_1 + A_2) - \det(A_1 - A_2)]^2 - 4\det[A_1]\det[A_2] \\ &= \frac{1}{4}\left[\det\left(\begin{bmatrix} a_{111} & a_{112} \\ a_{121} & a_{122}\end{bmatrix} + \begin{bmatrix} a_{211} & a_{221} \\ a_{212} & a_{222}\end{bmatrix}\right) - \det\left(\begin{bmatrix} a_{111} & a_{121} \\ a_{112} & a_{122}\end{bmatrix} - \begin{bmatrix} a_{211} & a_{221} \\ a_{212} & a_{222}\end{bmatrix}\right)\right]^2 \\ &\qquad - 4\det\begin{bmatrix} a_{111} & a_{121} \\ a_{112} & a_{122}\end{bmatrix}\det\begin{bmatrix} a_{211} & a_{221} \\ a_{212} & a_{222}\end{bmatrix}.\end{aligned}$$

   The statement that the gradient $\nabla A(\mathbf{x}, \mathbf{y}, \mathbf{z})$ of the trilinear functional defined by A vanishes for some nonzero vectors $\mathbf{x}, \mathbf{y}, \mathbf{z}$ is the statement that the system of bilinear equations,

$$\begin{aligned} a_{111}x_1y_1 + a_{121}x_1y_2 + a_{211}x_2y_1 + a_{221}x_2y_2 &= 0, \\ a_{112}x_1y_1 + a_{122}x_1y_2 + a_{212}x_2y_1 + a_{222}x_2y_2 &= 0, \\ a_{111}x_1z_1 + a_{112}x_1z_2 + a_{211}x_2z_1 + a_{212}x_2z_2 &= 0, \\ a_{121}x_1z_1 + a_{122}x_1z_2 + a_{221}x_2z_1 + a_{222}x_2z_2 &= 0, \\ a_{111}y_1z_1 + a_{112}y_1z_2 + a_{121}y_2z_1 + a_{122}y_2z_2 &= 0, \\ a_{211}y_1z_1 + a_{212}y_1z_2 + a_{221}y_2z_1 + a_{222}y_2z_2 &= 0, \end{aligned}$$

   has a non-trivial solution ($\mathbf{x}, \mathbf{y}, \mathbf{z}$ all non-zero).
3. The geometric hyperdeterminant of $A = [a_{ijk}] \in \mathbb{C}^{2\times 2\times 3}$ is

$$\begin{aligned}\mathrm{Det}_{2,2,3}(A) = \det\begin{bmatrix} a_{111} & a_{112} & a_{113} \\ a_{211} & a_{212} & a_{213} \\ a_{121} & a_{122} & a_{123}\end{bmatrix}\det\begin{bmatrix} a_{211} & a_{212} & a_{213} \\ a_{121} & a_{122} & a_{123} \\ a_{221} & a_{222} & a_{223}\end{bmatrix} \\ - \det\begin{bmatrix} a_{111} & a_{112} & a_{113} \\ a_{211} & a_{212} & a_{213} \\ a_{221} & a_{222} & a_{223}\end{bmatrix}\det\begin{bmatrix} a_{111} & a_{112} & a_{113} \\ a_{121} & a_{122} & a_{123} \\ a_{221} & a_{222} & a_{223}\end{bmatrix}.\end{aligned}$$

   The statement that the gradient $\nabla A(\mathbf{x}, \mathbf{y}, \mathbf{z})$ of the trilinear functional defined by A vanishes for some nonzero vectors $\mathbf{x}, \mathbf{y}, \mathbf{z}$ is the statement that the system of bilinear equations,

$$\begin{aligned} a_{111}x_1y_1 + a_{121}x_1y_2 + a_{211}x_2y_1 + a_{221}x_2y_2 &= 0, \\ a_{112}x_1y_1 + a_{122}x_1y_2 + a_{212}x_2y_1 + a_{222}x_2y_2 &= 0, \\ a_{113}x_1y_1 + a_{123}x_1y_2 + a_{213}x_2y_1 + a_{223}x_2y_2 &= 0, \\ a_{111}x_1z_1 + a_{112}x_1z_2 + a_{113}x_1z_3 + a_{211}x_2z_1 + a_{212}x_2z_2 + a_{213}x_2z_3 &= 0, \\ a_{121}x_1z_1 + a_{122}x_1z_2 + a_{123}x_1z_3 + a_{221}x_2z_1 + a_{222}x_2z_2 + a_{223}x_2z_3 &= 0, \\ a_{111}y_1z_1 + a_{112}y_1z_2 + a_{113}y_1z_3 + a_{121}y_2z_1 + a_{122}y_2z_2 + a_{123}y_2z_3 &= 0, \\ a_{211}y_1z_1 + a_{212}y_1z_2 + a_{213}y_1z_3 + a_{221}y_2z_1 + a_{222}y_2z_2 + a_{223}y_2z_3 &= 0, \end{aligned}$$

   has a non-trivial solution ($\mathbf{x}, \mathbf{y}, \mathbf{z}$ all non-zero).

Applications:

1. In Example 15.3.4, we saw how one may characterize the notion of a pure state in terms of the rank of a hypermatrix, namely $\operatorname{rank}(A) = 1$. The hyperdeterminant characterizes the dual notion — the *degenerate entangled states* are precisely the hypermatrices $A \in \mathbb{C}^{2\times 2\times 2}$ with $\mathrm{Det}_{2,2,2}(A) = 0$ [MW02]. More generally, when $\mathrm{Det}_{2,2,2}(A) \neq 0$, the magnitude of the hyperdeterminant $|\mathrm{Det}_{2,2,2}(A)|$ gives another way to measure the amount of entanglement called the *concurrence* [HW97].

15.10 Odds and Ends

Because of page constraints, many topics have to be omitted from this chapter: covariance and contravariance, tensor fields and hypermatrix-valued functions, symmetric tensors and symmetric hypermatrices, alternating tensors and skew-symmetric hypermatrices, eigenvalues and singular values of hypermatrices, positive definite hypermatrices and Cholesky decomposition, nonnegative hypermatrices and the Perron-Frobenius theorem, the Dirac and Einstein notations, tensor products of modules, of Hilbert and Banach spaces, of functions, of operators, of representations, etc.

Also, topics that are best presented in a usual narrative format (as opposed to a handbook format) are not included in the chapter. These include discussions of the difference between hypermatrices and tensors, the existence of canonical forms for hypermatrices, the duality between the geometric hyperdeterminant and tensor rank, questions relating to computability and complexity, as well as connections to algebraic geometry and representation theory.

As a consequence, there are many additonal interesting applications and examples that are not included in this chapter because they require one or more of these omitted topics. These include self-concordance and higher optimality conditions in optimization theory, Riemann curvature tensor and the Einstein field equations in general relativity, electromagnetic field tensor in gauge theory, linear piezoelectric equations in continuum mechanics, Fourier coefficients of triply-periodic functions in X-ray crystallography, other forms of the Yang–Baxter equation, density matrix renormalization group (DMRG) techniques in quantum chemistry, the Salmon conjecture (now a theorem) in phylogenetics, moments and cumulants in statistics, polynomial Mercer kernels and naïve Bayes model in machine learning, and blind source separation and independent components analysis in signal processing.

We refer the reader to [Lim] for an expanded treatment that covers these and other topics.

Acknowledgment

The author would like to express his heartfelt gratitude to Leslie Hogben for her tireless editorial efforts, transforming a manuscript that is an earlier version of [Lim] into the HLA format that one sees here. It is an arduous undertaking without which this chapter would not have made it in time for inclusion in this volume. The author would also like to thank Harm Derksen, Shenglong Hu, J. M. Landsberg, Peter McCullagh, and Ke Ye for their very helpful comments.

Matrix Equalities and Inequalities

Michael Tsatsomeros
Washington State University

16.1 Eigenvalue Equalities and Inequalities 16-1
16.2 Spectrum Localization 16-5
16.3 Inequalities for the Singular Values and the Eigenvalues 16-8
16.4 Basic Determinantal Relations 16-11
16.5 Rank and Nullity Equalities and Inequalities 16-14
16.6 Useful Identities for the Inverse 16-16
References 16-18

In this chapter, we have collected classical equalities and inequalities regarding the eigenvalues, the singular values, the determinant, and the dimensions of the fundamental subspaces of a matrix. Also included is a section on identities for matrix inverses. The majority of these results can be found in comprehensive books on linear algebra and matrix theory, although some are of specialized nature. The reader is encouraged to consult, e.g., [HJ85], [HJ91], [MM92], or [Mey00] for details, proofs, and further bibliography.

Recall that $\sigma(A)$ denotes the (multiset) of the eigenvalues of a square matrix A.

16.1 Eigenvalue Equalities and Inequalities

The majority of the facts in this section concern general matrices; however, some classical and frequently used results on eigenvalues of Hermitian and positive definite matrices are also included. For the latter, see also Chapter 9 and [HJ85, Chap. 4]. Many of the definitions and some of the facts in this section are also given in Section 4.4.

Facts:

1. [HJ85, Chap. 1] Let $A \in F^{n\times n}$, where $F = \mathbb{C}$ or any algebraically closed field. Let $p_A(x) = \det(xI - A)$ be the characteristic polynomial of A, and $\lambda_1, \lambda_2, \ldots, \lambda_n$ be the eigenvalues of A. Denote by $S_k(\lambda_1, \ldots, \lambda_n)(k = 1, 2, \ldots, n)$ the kth elementary symmetric function of the eigenvalues (here abbreviated $S_k(\lambda)$), and by $S_k(A)$ the sum of all $k \times k$ principal minors of A. Then

   (a) The characteristic polynomial satisfies

   $$\begin{aligned} p_A(x) &= (x-\lambda_1)(x-\lambda_2)\cdots(x-\lambda_n) \\ &= x^n - S_1(\lambda)x^{n-1} + S_2(\lambda)x^{n-2} + \cdots + (-1)^{n-1}S_{n-1}(\lambda)x + (-1)^n S_n(\lambda) \\ &= x^n - S_1(A)x^{n-1} + S_2(A)x^{n-2} + \cdots + (-1)^{n-1}S_{n-1}(A)x + (-1)^n S_n(A). \end{aligned}$$

   (b) $S_k(\lambda) = S_k(\lambda_1, \ldots, \lambda_n) = S_k(A)(k = 1, 2, \ldots, n)$.

   (c) $\mathrm{tr}A = S_1(A) = \sum_{i=1}^n a_{ii} = \sum_{i=1}^n \lambda_i$ and $\det A = S_n(A) = \prod_{i=1}^n \lambda_i$.

2. [HJ85, (1.2.13)] Let $A(i)$ be obtained from $A \in \mathbb{C}^{n\times n}$ by deleting row and column i. Then
$$\frac{d}{dx}p_A(x) = \sum_{i=1}^{n} p_{A(i)}(x).$$
Facts 3 to 9 are collected, together with historical commentary, proofs, and further references, in [MM92, Chap. III].
3. (Hirsch and Bendixson) Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ and λ be an eigenvalue of A. Denote $B = [b_{ij}] = (A + A^*)/2$ and $C = [c_{ij}] = (A - A^*)/(2i)$. Then the following inequalities hold:
$$|\lambda| \leq n \max_{i,j} |a_{ij}|,$$
$$|\text{Re}\lambda| \leq n \max_{i,j} |b_{ij}|,$$
$$|\text{Im}\lambda| \leq n \max_{i,j} |c_{ij}|.$$
Moreover, if $A + A^T \in \mathbb{R}^{n\times n}$, then
$$|\text{Im}\lambda| \leq \max_{i,j} |c_{ij}| \sqrt{\frac{n(n-1)}{2}}.$$
4. (Pick's inequality) Let $A \in \mathbb{R}^{n\times n}$ and λ be an eigenvalue of A. Denote $C = [c_{ij}] = (A - A^T)/2$. Then
$$|\text{Im}\lambda| \leq \max_{i,j} |c_{ij}| \cot\left(\frac{\pi}{2n}\right).$$
5. Let $A \in \mathbb{C}^{n\times n}$ and λ be an eigenvalue of A. Consider the Hermitian matrices $B = (A + A^*)/2$ and $C = (A - A^*)/(2i)$, and let their ordered eigenvalues be
$$\mu_1 \geq \mu_2 \geq \ldots \geq \mu_n \quad \text{and} \quad \nu_1 \geq \nu_2 \geq \ldots \geq \nu_n,$$
respectively. Then the following inequalities hold:
$$\mu_n \leq \text{Re}\lambda \leq \mu_1,$$
$$\nu_n \leq \text{Im}\lambda \leq \nu_1.$$
Let also y be an eigenvector of B corresponding to μ_1 normalized so that $\|y\|_2 = 1$ and denote $v = \|By\|_2^2, \quad u = \text{Im}(y^*By)$. Then [AT06]
$$(\text{Re}\lambda - \mu_2)(\text{Im}\lambda - u))^2 \leq (\mu_1 - \text{Re}\lambda)[v - u^2 + (\text{Re}\lambda - \mu_2)(\text{Re}\lambda - \mu_1)].$$
6. (Schur's inequality) Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ have eigenvalues λ_j $(j = 1, 2, \ldots, n)$. Then
$$\sum_{j=1}^{n} |\lambda_j|^2 \leq \sum_{i,j=1}^{n} |a_{ij}|^2$$
with equality holding if and only if A is a normal matrix (i.e., $A^*A = AA^*$). (See Section 8.2 for more information on normal matrices.)
7. (Browne's Theorem) Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ and $\lambda_j (j = 1, 2, \ldots, n)$ be the eigenvalues of A ordered so that $|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_n|$. Let also $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_n$ be the singular values of A, which are real and nonnegative. (See Section 5.6 for the definition.) Then
$$\sigma_n \leq |\lambda_j| \leq \sigma_1 \quad (j = 1, 2, \ldots, n).$$

In fact, the following more general statement holds:

$$\prod_{i=1}^{k}\sigma_{n-i+1} \leq \prod_{j=1}^{k}|\lambda_{t_j}| \leq \prod_{i=1}^{k}\sigma_i,$$

for every $k \in \{1, 2, \ldots, n\}$ and every k-tuple $(t_1, t_2, \ldots, t_k)$ of strictly increasing elements chosen from $\{1, 2, \ldots, n\}$.

8. Let $A \in \mathbb{C}^{n\times n}$ and R_i, C_i $(i = 1, 2, \ldots, n)$ denote the sums of the absolute values of the entries of A in row i and column i, respectively. Also denote

$$R = \max_i\{R_i\} \quad \text{and} \quad C = \max_i\{C_i\}.$$

Let λ be an eigenvalue of A. Then the following inequalities hold:

$$|\lambda| \leq \max_i \frac{R_i + C_i}{2} \leq \frac{R + C}{2},$$
$$|\lambda| \leq \max_i \sqrt{R_i C_i} \leq \sqrt{RC},$$
$$|\lambda| \leq \min\{R, C\}.$$

9. (Schneider's Theorem) Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ and $\lambda_j (j = 1, 2, \ldots, n)$ be the eigenvalues of A ordered so that $|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_n|$. Let $\mathbf{x} = [x_i]$ be any vector in $\mathbb{R}^n$ with positive entries and define the quantities

$$r_i = \sum_{j=1}^{n} \frac{|a_{ij}|x_j}{x_i} \qquad (i = 1, 2, \ldots, n).$$

Then

$$\prod_{j=1}^{k}|\lambda_j| \leq \prod_{j=1}^{k} r_{i_j} \quad (k = 1, 2, \ldots, n)$$

for all n-tuples $(i_1, i_2, \ldots, i_n)$ of elements from $\{1, 2, \ldots, n\}$ such that

$$r_{i_1} \geq r_{i_2} \geq \cdots \geq r_{i_n}.$$

10. [HJ85, Theorem 8.1.18] For $A = [a_{ij}] \in \mathbb{C}^{n\times n}$, let its entrywise absolute value be denoted by $|A| = [|a_{ij}|]$. Let $B \in \mathbb{C}^{n\times n}$ and assume that $|A| \leq B$ (entrywise). Then

$$\rho(A) \leq \rho(|A|) \leq \rho(B).$$

11. [HJ85, Chap. 5, Sec. 6] Let $A \in \mathbb{C}^{n\times n}$ and $\|\cdot\|$ denote any matrix norm on $\mathbb{C}^{n\times n}$. (See Chapter 50). Then

$$\rho(A) \leq \|A\|$$

and

$$\lim_{k\longrightarrow\infty} \|A^k\|^{1/k} = \rho(A).$$

12. [HJ91, Corollary 1.5.5] Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$. The numerical range of $A \in \mathbb{C}^{n\times n}$ is $W(A) = \{v^*Av \in \mathbb{C} : v \in \mathbb{C}^n \text{ with } v^*v = 1\}$ and the numerical radius of $A \in \mathbb{C}^{n\times n}$ is $r(A) = \max\{|z| : z \in W(A)\}$. (See Chapter 25 for more information about the numerical range and numerical radius.) Then the following inequalities hold:

$$r(A^m) \leq [r(A)]^m \quad (m = 1, 2, \ldots),$$
$$\rho(A) \leq r(A) \leq \frac{\|A\|_1 + \|A\|_\infty}{2},$$
$$\frac{\|A\|_2}{2} \leq r(A) \leq \|A\|_2,$$
$$r(A) \leq r(|A|) = \frac{|A| + |A|^T}{2} \quad (\text{where } |A| = [|a_{ij}|]).$$

Moreover, the following statements are equivalent:

(a) $r(A) = \|A\|_2$.

(b) $\rho(A) = \|A\|_2$.

(c) $\|A^n\|_2 = \|A\|_2^n$.

(d) $\|A^k\|_2 = \|A\|_2^k \quad (k = 1, 2, \ldots)$.

Facts 13 to 15 below, along with proofs, can be found in [HJ85, Chap. 4].

13. (Rayleigh–Ritz) Let $A \in \mathbb{C}^{n\times n}$ be Hermitian (i.e., $A = A^*$) with eigenvalues $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$. Then

    (a) $\lambda_n x^*x \leq x^*Ax \leq \lambda_1 x^*x$ for all $x \in \mathbb{C}^n$.

    (b) $\lambda_1 = \max\limits_{x\neq 0} \dfrac{x^*Ax}{x^*x} = \max\limits_{x^*x=1} x^*Ax$.

    (c) $\lambda_n = \min\limits_{x\neq 0} \dfrac{x^*Ax}{x^*x} = \min\limits_{x^*x=1} x^*Ax$.

14. (Courant–Fischer) Let $A \in \mathbb{C}^{n\times n}$ be Hermitian with eigenvalues $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$. Let $k \in \{1, 2, \ldots, n\}$. Then

$$\begin{aligned}\lambda_k &= \min_{w_1,w_2,\ldots,w_{k-1}\in\mathbb{C}^n} \quad \max_{\substack{x\neq 0, x\in\mathbb{C}^n \\ x\perp w_1,w_2,\ldots,w_{k-1}}} \frac{x^*Ax}{x^*x} \\ &= \max_{w_1,w_2,\ldots,w_{n-k}\in\mathbb{C}^n} \quad \min_{\substack{x\neq 0, x\in\mathbb{C}^n \\ x\perp w_1,w_2,\ldots,w_{n-k}}} \frac{x^*Ax}{x^*x}.\end{aligned}$$

15. (Weyl) Let $A, B \in \mathbb{C}^{n\times n}$ be Hermitian. Consider the eigenvalues of A, B, and $A+B$, denoted by $\lambda_i(A), \lambda_i(B), \lambda_i(A+B)$, respectively, arranged in decreasing order. Then the following hold:

    (a) For each $k \in \{1, 2, \ldots, n\}$,

$$\lambda_k(A) + \lambda_n(B) \leq \lambda_k(A+B) \leq \lambda_k(A) + \lambda_1(B).$$

    (b) For every pair $j, k \in \{1, 2, \ldots, n\}$ such that $j + k \geq n + 1$,

$$\lambda_{j+k-n}(A+B) \geq \lambda_j(A) + \lambda_k(B).$$

    (c) For every pair $j, k \in \{1, 2, \ldots, n\}$ such that $j + k \leq n + 1$,

$$\lambda_j(A) + \lambda_k(B) \geq \lambda_{j+k-1}(A+B).$$

Examples:

1. To illustrate several of the facts in this section, consider

$$A = \begin{bmatrix} 1 & -1 & 0 & 2 \\ 3 & 1 & -2 & 1 \\ 1 & 0 & 0 & -1 \\ -1 & 2 & 1 & 0 \end{bmatrix},$$

whose spectrum, $\sigma(A)$, consists of

$$\lambda_1 = -0.7112 + 2.6718i, \lambda_2 = -0.7112 - 2.6718i, \lambda_3 = 2.5506, \lambda_4 = 0.8719.$$

Note that the eigenvalues are ordered decreasingly with respect to their moduli (absolute values):

$$|\lambda_1| = |\lambda_2| = 2.7649 > |\lambda_3| = 2.5506 > |\lambda_4| = 0.8719.$$

The maximum and minimum eigenvalues of $(A + A^*)/2$ are 2.8484 and -1.495. Note that, as required by Fact 5, for every $\lambda \in \sigma(A)$,

$$-1.495 \leq \operatorname{Re}\lambda \leq 2.8484.$$

To illustrate Fact 7, let $(t_1, t_2) = (1, 3)$ and compute the singular values of A:

$$\sigma_1 = 4.2418, \sigma_2 = 2.5334, \sigma_3 = 1.9890, \sigma_4 = 0.7954.$$

Then, indeed,

$$\sigma_4\sigma_3 = 1.5821 \leq |\lambda_1||\lambda_3| = 7.0522 \leq \sigma_1\sigma_2 = 10.7462.$$

Referring to the notation in Fact 8, we have $C = 6$ and $R = 7$. The spectral radius of A is $\rho(A) = 2.7649$ and, thus, the modulus of every eigenvalue of A is indeed bounded above by the quantities

$$\frac{R+C}{2} = \frac{13}{2} = 6.5, \quad \sqrt{RC} = 6.4807, \quad \min\{R, C\} = 6.$$

Letting B denote the entrywise absolute value of A, Facts 10 and 11 state that

$$\rho(A) = 2.7649 \leq \rho(B) = 4.4005 \quad \text{and} \quad \rho(A) = 2.7649 \leq \|A\|_2 = 4.2418.$$

Examples related to Fact 12 and the numerical range are found in Chapter 25.

2. Consider the matrix

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$$

and note that for every integer $m \geq 2$, A^m consists of zero entries, except for its $(1, 1)$ entry that is equal to 1. One may easily verify that

$$\rho(A) = 1, \quad \|A\|_\infty = \|A\|_1 = \|A\|_2 = 1.$$

By Fact 12, it follows that $r(A) = 1$ and all of the equivalent conditions (a) to (d) in that fact hold, despite A not being a normal matrix.

16.2 Spectrum Localization

This section presents inclusion regions for the eigenvalues of a matrix.

Definitions:

Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ and define the quantities

$$R_i = \sum_{\substack{j=1 \\ j\neq i}}^{n} |a_{ij}| \quad (i = 1, 2, \ldots, n).$$

The **Geršgorin** discs (centered at a_{ii} with radii R_i) are

$$D_i = \{z \in \mathbb{C} : |z - a_{ii}| \leq R_i\} \quad (i = 1, 2, \ldots, n).$$

Facts:

Most of the following facts, along with proofs, details, and additional references, can be found in [MM92, Chap. III, Sec. 2], [HJ85, Chap. 6], and [Bru82].

1. (Geršgorin) Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$. Then all the eigenvalues of A lie in the union of the Geršgorin discs; that is,
$$\sigma(A) \subseteq \bigcup_{i=1}^{n} D_i.$$
Moreover, if the union of k Geršgorin discs, G, forms a connected region disjoint from the remaining $n-k$ discs, then G contains exactly k eigenvalues of A (counting algebraic multiplicities).
2. (Lévy–Desplanques) Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ be a strictly diagonally dominant matrix, namely,
$$|a_{ii}| \ > \sum_{\substack{j=1\\ j\neq i}}^{n} |a_{ij}| \quad (i = 1, 2, \dots, n).$$
Then A is an invertible matrix.
3. (Brauer) Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ and define the quantities
$$R_i = \sum_{\substack{j=1\\ j\neq i}}^{n} |a_{ij}| \quad (i = 1, 2, \dots, n).$$
Consider the *ovals of Cassini*, which are defined by
$$V_{i,j} = \{z \in \mathbb{C} : |z - a_{ii}||z - a_{jj}| \leq R_i R_j\} \quad (i, j = 1, 2, \dots, n, i \neq j).$$
Then all the eigenvalues of A lie in the union of the ovals of Cassini; that is,
$$\sigma(A) \subseteq \bigcup_{\substack{i,j=1\\ i\neq j}}^{n} V_{i,j}.$$
4. [VK99, Eq. 3.1] Denoting the union of the Geršgorin discs of $A \in \mathbb{C}^{n\times n}$ by $\Gamma(A)$ (see Fact 1) and the union of the ovals of Cassini of A by $K(A)$ (see Fact 3), we have that
$$\sigma(A) \subseteq K(A) \subseteq \Gamma(A).$$
That is, the ovals of Cassini provided at least as good a localization for the eigenvalues of A as do the Geršgorin discs.
5. Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ such that
$$|a_{ii}||a_{kk}| \ > \sum_{\substack{j=1\\ j\neq i}}^{n} |a_{ij}| \sum_{\substack{j=1\\ j\neq k}}^{n} |a_{kj}| \quad (i, k = 1, 2, \dots, n, i \neq k).$$
Then A is an invertible matrix.
6. Facts 1 to 5 can also be stated in terms of *column sums* instead of row sums.
7. (Ostrowski) Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ and $\alpha \in [0, 1]$. Define the quantities
$$R_i = \sum_{\substack{j=1\\ j\neq i}}^{n} |a_{ij}|, \qquad C_i = \sum_{\substack{j=1\\ j\neq i}}^{n} |a_{ji}| \quad (i = 1, 2, \dots, n).$$
Then all the eigenvalues of A lie in the union of the discs
$$D_i(\alpha) = \left\{z \in \mathbb{C} : |z - a_{ii}| \leq R_i^{\alpha} C_i^{1-\alpha}\right\} \quad (i = 1, 2, \dots, n);$$

that is,

$$\sigma(A) \subseteq \bigcup_{i=1}^{n} D_i(\alpha).$$

8. [AT06], [PT12] The inequalities of Fact 16.1.5 define regions in the complex plane that contain the eigenvalues of a matrix A. In particular, the last inequality in that fact gives rise to the cubic algebraic curve in $s, t \in \mathbb{R}$

$$\Gamma(A) = \{s + i\,t : \; s, t \in \mathbb{R}, \; (\mu_2 - s)[(\mu_1 - s)^2 + (u - t)^2] \quad + (\mu_1 - s)(v - u^2) = 0\}$$

and the complex region

$$\Gamma_{\text{in}}(A) = \{s + i\,t : \; s, t \in \mathbb{R}, \; (\mu_2 - s)[(\mu_1 - s)^2 + (u - t)^2] \quad + (\mu_1 - s)(v - u^2) \geq 0\}.$$

Then (as illustrated by an example below)

$$\sigma(A) \subset \Gamma_{in}(A).$$

9. Let $A \in \mathbb{C}^{n\times n}$ and consider its numerical range, $W(A)$. In the notation of Fact 8, consider the **(cubic) envelope** of A defined by

$$E(A) \; = \bigcap_{\theta\in[0,2\pi]} e^{-i\,\theta}\,\Gamma_{\text{in}}(e^{i\,\theta}A).$$

Then [PT12]

$$\sigma(A) \;\subseteq\; E(A) \;\subseteq\; W(A).$$

In particular, if A is a normal matrix (i.e., $A^*A = AA^*$), then $W(A)$ coincides with the convex hull of the eigenvalues of A.

Examples:

1. To illustrate Fact 1 (see also Facts 3 and 4) let

$$A = \begin{bmatrix} 3i & 1 & 0.5 & -1 & 0 \\ -1 & 2i & 1.5 & 0 & 0 \\ 1 & 2 & -7 & 0 & 1 \\ 0 & -1 & 0 & 10 & i \\ 1 & 0 & 1 & -1 & 1 \end{bmatrix}$$

and consider the Geršgorin discs of A displayed in Figure 16.1. Note that there are three connected regions of discs that are disjoint of each other. Each region contains as many eigenvalues (marked with +'s) as the number of discs it comprises. The ovals of Cassini are contained in the union of the Geršgorin discs. In general, although it is easy to verify whether a complex number belongs to an oval of Cassini or not, these ovals are generally difficult to draw. An interactive supplement to [VK99], accessible at
`www.emis.math.ca/EMIS/journals/ETNA/vol.8.1999/pp15-20.dir/gershini.html`
allows one to draw and compare the Geršgorin discs and ovals of Cassini of 3×3 matrices.

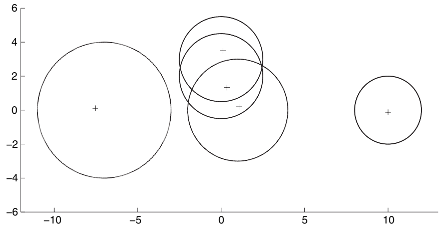

FIGURE 16.1 The Geršgorin disks of A.

2. The configuration of the curve $\Gamma(A)$ (and thus the shape of the eigenvalue inclusion region $\Gamma_{\text{in}}(A)$) in Fact 8 depends on the sign of the quantity

$$\Delta = (\mu_1 - \mu_2)^2 - 4(v - u^2).$$

The three possible situations are illustrated in Figure 16.2 for three appropriately chosen 3×3 matrices whose eigenvalues are marked by +'s.

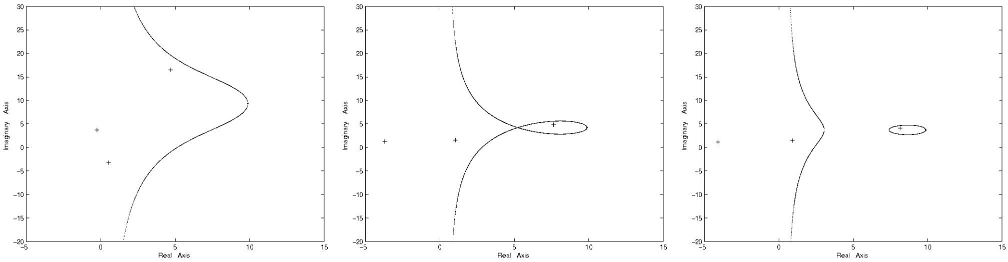

FIGURE 16.2 The cases of $\Gamma(A)$ with $\Delta < 0$ (left), $\Delta = 0$ (middle), and $\Delta > 0$ (right).

3. To illustrate Fact 9, consider the matrices

$$A = \begin{bmatrix} 1 & -1 & 2 \\ 2 & -1 & 0 \\ -1 & 0 & 1 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 2+2i & -2-i & -1-2i \\ 1+2i & -1-i & -1-2i \\ 2+i & -2-i & -1-i \end{bmatrix}.$$

Note that B is a normal matrix with spectrum $\{1, i, -1-i\}$. As indicated in Figure 16.3, the numerical ranges of A and B contain the eigenvalues of A and B, respectively, marked by +'s. The numerical range of B is indeed the convex hull of the eigenvalues.

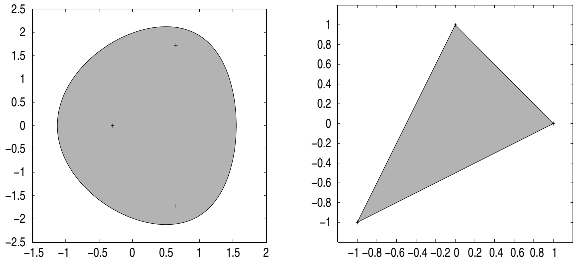

FIGURE 16.3 The numerical range of A and of the normal matrix B.

4. To illustrate the envelope in Fact 9, consider the 11×11 real Frank matrix C (that can be generated by the Matlab command `frank(11)`). The envelope $E(C)$ is the unshaded region depicted in Figure 16.4; the outer pear-shaped curve is the boundary of the numerical range of C, and the eigenvalues of C are again marked by +'s.

16.3 Inequalities for the Singular Values and the Eigenvalues

The material in this section is a selection of classical inequalities about the singular values. Extensive details and proofs, as well as a host of additional results on singular values, can be found in [HJ91, Chap. 3]. Definitions of many of the terms in this section are given in Section 5.6, Chapter 24, and Chapter 58; additional facts and examples are also given there.

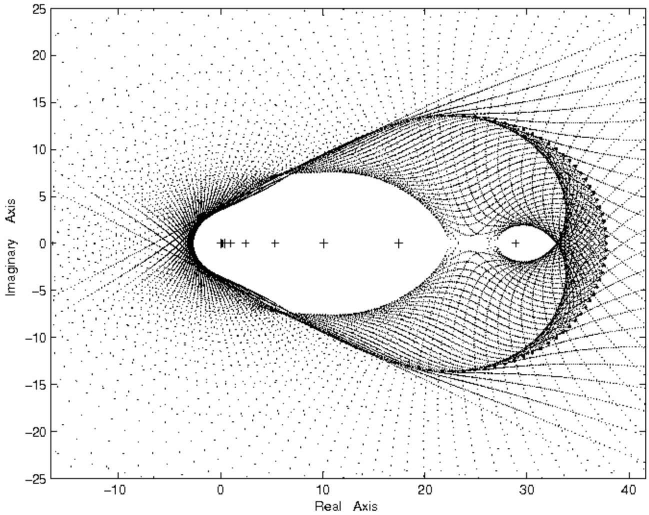

FIGURE 16.4 The envelope of the 11×11 Frank matrix C.

Facts:

1. Let $A \in \mathbb{C}^{m\times n}$ and σ_1 be its largest singular value. Then

$$\sigma_1 = \|A\|_2.$$

2. Let $A \in \mathbb{C}^{m\times n}$, $q = \min\{m, n\}$. Denote the singular values of A by $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_q$ and let $k \in \{1, 2, \ldots, q\}$. Then

$$\begin{aligned}\sigma_k &= \min_{w_1,w_2,\ldots,w_{k-1}\in\mathbb{C}^n} \max_{\substack{\|x\|_2=1, x\in\mathbb{C}^n \\ x\perp w_1,w_2,\ldots,w_{k-1}}} \|Ax\|_2 \\ &= \max_{w_1,w_2,\ldots,w_{n-k}\in\mathbb{C}^n} \min_{\substack{\|x\|_2=1, x\in\mathbb{C}^n \\ x\perp w_1,w_2,\ldots,w_{n-k}}} \|Ax\|_2 \\ &= \min_{\substack{W\subseteq\mathbb{C}^n \\ \dim W=n-k+1}} \max_{\substack{x\in W \\ \|x\|_2=1}} \|Ax\|_2 \\ &= \max_{\substack{W\subseteq\mathbb{C}^n \\ \dim W=k}} \min_{\substack{x\in W \\ \|x\|_2=1}} \|Ax\|_2,\end{aligned}$$

where the optimizations take place over all subspaces $W \subseteq \mathbb{C}^n$ of the indicated dimensions.

3. (Weyl) Let $A \in \mathbb{C}^{n\times n}$ have singular values $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_n$ and eigenvalues λ_j $(j = 1, 2, \ldots, n)$ be ordered so that $|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_n|$. Then

$$|\lambda_1\lambda_2\cdots\lambda_k| \leq \sigma_1\sigma_2\cdots\sigma_k \qquad (k = 1, 2, \ldots, n). \tag{16.1}$$

Equality holds in Eq. (16.1) when $k = n$.

4. (A. Horn) Let $A \in \mathbb{C}^{m\times p}$ and $B \in \mathbb{C}^{p\times n}$. Let also $r = \min\{m, p\}, s = \min\{p, n\}$, and $q = \min\{r, s\}$. Denote the singular values of A, B, and AB, respectively, by $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_r$, $\tau_1 \geq \tau_2 \geq \cdots \geq \tau_s$, and $\chi_1 \geq \chi_2 \geq \cdots \geq \chi_q$. Then

$$\prod_{i=1}^{k} \chi_i \leq \prod_{i=1}^{k} \sigma_i\tau_i \quad (k = 1, 2, \ldots, q).$$

Equality holds if $k = n = p = m$. Also for any $t > 0$,

$$\sum_{i=1}^{k} \chi_i^t \leq \sum_{i=1}^{k} (\sigma_i \tau_i)^t \quad (k = 1, 2, \ldots, q).$$

5. Let $A \in \mathbb{C}^{n \times n}$ have singular values $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_n$ and eigenvalues λ_j $(j = 1, 2, \ldots, n)$ ordered so that $|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_n|$. Then for any $t > 0$,

$$\sum_{i=1}^{k} |\lambda_i|^t \leq \sum_{i=1}^{k} \sigma_i^t \quad (k = 1, 2 \ldots, n).$$

   In particular, for $t = 1$ and $k = n$ we obtain from the inequality above that

$$|\mathrm{tr} A| \leq \sum_{i=1}^{n} \sigma_i.$$

6. Let $A, B \in \mathbb{C}^{m \times n}$ and $q = \min\{m, n\}$. Denote the singular values of A, B, and $A+B$, respectively, by $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_q$, $\tau_1 \geq \tau_2 \geq \cdots \geq \tau_q$, and $\psi_1 \geq \psi_2 \geq \cdots \geq \psi_q$. Then the following inequalities hold:
   (a) $\psi_{i+j-1} \leq \sigma_i + \tau_j \quad (1 \leq i, j \leq q, \quad i + j \leq q + 1)$.
   (b) $|\rho_i - \sigma_i| \leq \tau_1 \quad (i = 1, 2, \ldots, q)$.
   (c) $\displaystyle\sum_{i=1}^{k} \psi_i \leq \sum_{i=1}^{k} \sigma_i + \sum_{i=1}^{k} \tau_i \quad (k = 1, 2, \ldots, q)$.

7. Let $A \in \mathbb{C}^{n \times n}$ have eigenvalues λ_j $(j = 1, 2, \ldots, n)$ ordered so that $|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_n|$. Denote the singular values of A^k by $\sigma_1(A^k) \geq \sigma_2(A^k) \geq \cdots \geq \sigma_n(A^k)$. Then

$$\lim_{k \longrightarrow \infty} [\sigma_i(A^k)]^{1/k} = |\lambda_i| \qquad (i = 1, 2, \ldots, n).$$

Examples:

1. To illustrate Facts 1, 3, and 5, as well as gauge the bounds they provide, let

$$A = \begin{bmatrix} i & 2 & -1 & 0 \\ 2 & 1+i & 1 & 0 \\ 2i & 1 & 1 & 0 \\ 0 & 1-i & 1 & 0 \end{bmatrix},$$

   whose eigenvalues and singular values ordered as required in Fact 3 are, respectively,

$$\lambda_1 = 2.6775 + 1.0227i, \ \lambda_2 = -2.0773 + 1.4685i, \ \lambda_3 = 1.3998 - 0.4912i, \ \lambda_4 = 0,$$

   and

$$\sigma_1 = 3.5278, \sigma_2 = 2.5360, \sigma_3 = 1.7673, \sigma_4 = 0.$$

According to Fact 1, $\|A\|_2 = \sigma_1 = 3.5278$. The following inequalities hold according to Fact 3:

$$7.2914 = |\lambda_1\lambda_2| \leq \sigma_1\sigma_2 = 8.9465.$$
$$10.8167 = |\lambda_1\lambda_2\lambda_3| \leq \sigma_1\sigma_2\sigma_3 = 15.8114.$$

Finally, applying Fact 5 with $t = 3/2$ and $k = 2$, we obtain the inequality

$$8.9099 = |\lambda_1|^{3/2} + |\lambda_2|^{3/2} \leq \sigma_1^{3/2} + \sigma_2^{3/2} = 10.6646.$$

For $t = 1$ and $k = n$, we get

$$2.8284 = |2 + 2i| = |\mathrm{tr}(A)| \leq \sum_{j=1}^{4} \sigma_j = 7.8311.$$

16.4 Basic Determinantal Relations

The purpose of this section is to review some basic equalities and inequalities regarding the determinant of a matrix over a field F. For most of the facts mentioned here, see [Mey00, Chap. 6] and [HJ85, Chap. 0]. Definitions of many of the terms in this section are given in Sections 4.1 and 4.2; additional facts and examples are given there as well. Note that this section concludes with a couple of classical determinantal inequalities for positive semidefinite matrices; see Section 9.4 or [HJ85, Chap. 7] for more on this subject.

Following are some of the properties of determinants of $n \times n$ matrices, as well as classical formulas for the determinant of A and its submatrices.

Facts:

1. The following are facts about the determinant of $A \in F^{n\times n}$. (See also Section 4.1.)
   (a) $\det A = \det A^T$; if $F = \mathbb{C}$, then $\det A^* = \overline{\det A}$.
   (b) If B is obtained from A by multiplying one row (or column) by a scalar c, then $\det B = c \det A$.
   (c) $\det(cA) = c^n \det A$ for any scalar c.
   (d) $\det(AB) = \det A \det B$. If A is invertible, then $\det A^{-1} = (\det A)^{-1}$.
   (e) If B is obtained from A by adding nonzero multiples of one row (respectively, column) to other rows (respectively, columns), then $\det B = \det A$.
   (f) $\det A = \sum_{\sigma \in S_n} \mathrm{sgn}(\sigma) a_{1\sigma(1)} a_{2\sigma(2)} \cdots a_{n\sigma(n)}$, where the summation is taken over all permutations σ of n letters and $\mathrm{sgn}(\sigma)$ denotes the sign of the permutation σ.
   (g) Let A_{ij} denote the $(n-1) \times (n-1)$ matrix obtained from $A \in F^{n\times n}$ $(n \geq 2)$ by deleting row i and column j. The following formula is known as the *Laplace expansion of* $\det A$ *along column* j:

$$\det A = \sum_{i=1}^{n} (-1)^{i+j} a_{ij} \det A_{ij} \quad (j = 1, 2, \ldots, n).$$

2. (Cauchy–Binet) Let $A \in F^{m,k}$, $B \in F^{k\times n}$ and consider the matrix $C = AB \in F^{m\times n}$. Let also $\alpha \subseteq \{1, 2, \ldots, m\}$ and $\beta \subseteq \{1, 2, \ldots, n\}$ have cardinality r, where $1 \leq r \leq \min\{m, k, n\}$. Then the submatrix of C whose rows are indexed by α and columns indexed by β satisfies

$$\det C[\alpha, \beta] = \sum_{\substack{\gamma \subseteq \{1,2,\ldots,k\} \\ |\gamma| = r}} \det A[\alpha, \gamma] \det B[\gamma, \beta].$$

3. [Mey00, Sec. 6.1, p. 471] Let $A = [a_{ij}(x)]$ be an $n \times n$ matrix whose entries are complex differentiable functions of x. Let D_i $(i = 1, 2, \ldots, n)$ denote the $n \times n$ matrix obtained from A when the entries in its ith row are replaced by their derivatives with respect to x. Then
$$\frac{d}{dx}(\det A) = \sum_{i=1}^{n} \det D_i.$$
4. Let $A = [a_{ij}]$ be an $n \times n$ matrix and consider its entries as independent variables. Then
$$\frac{\partial(\det A)}{\partial a_{ij}} = \det A(\{i\}, \{j\}) \quad (i, j = 1, 2, \ldots, n),$$
where $A(\{i\}, \{j\})$ denotes the submatrix of A obtained from A by deleting row i and column j.
5. [Mey00, Sec. 6.2] Let $A \in F^{n\times n}$ and $\alpha \subseteq \{1, 2, \ldots, n\}$. If the submatrix of A whose rows and columns are indexed by α, $A[\alpha]$, is invertible, then
$$\det A = \det A[\alpha] \det(A/A[\alpha]).$$
In particular, if A is partitioned in blocks as
$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix},$$
where A_{11} and A_{22} are square matrices, then
$$\det A = \begin{cases} \det A_{11} \det(A_{22} - A_{21}(A_{11})^{-1}A_{12}) & \text{if } A_{11} \text{ is invertible} \\ \det A_{22} \det(A_{11} - A_{12}(A_{22})^{-1}A_{21}) & \text{if } A_{22} \text{ is invertible.} \end{cases}$$
The following two facts for $F = \mathbb{C}$ can be found in [Mey00, Sec. 6.2, pp. 475, 483] and [Mey00, Exer. 6.2.15, p. 485], respectively. The proofs are valid for arbitrary fields.
6. Let $A \in F^{n\times n}$ be invertible and $c, d \in F^n$. Then
$$\det(A + cd^T) = \det(A)(1 + d^T A^{-1} c).$$
7. Let $A \in F^{n\times n}$ be invertible, $x, y \in F^n$. Then
$$\det \begin{bmatrix} A & x \\ y^T & -1 \end{bmatrix} = -\det(A + xy^T).$$
8. [HJ85, Theorem 7.8.1 and Corollary 7.8.2] (Hadamard's inequalities) Let $A = [a_{ij}] \in \mathbb{C}^{n\times n}$ be a positive semidefinite matrix. Then
$$\det A \leq \prod_{i=1}^{n} a_{ii}.$$
If A is positive definite, equality holds if and only if A is a diagonal matrix.
For a general matrix $B = [b_{ij}] \in \mathbb{C}^{n\times n}$, applying the above inequality to B^*B and BB^*, respectively, one obtains
$$|\det B| \leq \prod_{i=1}^{n} \left(\sum_{j=1}^{n} |b_{ij}|^2 \right)^{1/2} \quad \text{and} \quad |\det B| \leq \prod_{j=1}^{n} \left(\sum_{i=1}^{n} |b_{ij}|^2 \right)^{1/2}.$$
If B is nonsingular, equalities hold, respectively, if and only if the rows or the columns of B are orthogonal.

9. [HJ85, Theorem 7.8.3] (Fischer's inequality) Consider a positive definite matrix

$$A = \begin{bmatrix} X & Y \\ Y^* & Z \end{bmatrix},$$

partitioned so that X, Z are square and nonvacuous. Then

$$\det A \leq \det X \det Z.$$

Examples:

For examples relating to Facts 1, 2, and 5, see Chapter 4.

1. Let

$$A = \begin{bmatrix} 1 & 3 & -1 \\ 0 & 1 & 1 \\ -1 & 2 & 2 \end{bmatrix} \quad \text{and} \quad x = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, y = \begin{bmatrix} 2 \\ 1 \\ -1 \end{bmatrix}.$$

Then, as noted by Fact 7,

$$\det \begin{bmatrix} A & x \\ y^T & -1 \end{bmatrix} = \begin{bmatrix} 1 & 3 & -1 & 1 \\ 0 & 1 & 1 & 1 \\ -1 & 2 & 2 & 1 \\ 2 & 1 & -1 & -1 \end{bmatrix} = -\det(A + xy^T) = \begin{bmatrix} 3 & 4 & -2 \\ 2 & 2 & 0 \\ 1 & 3 & 1 \end{bmatrix} = 10.$$

Next, letting $c = [121]^T$ and $d = [0 - 1 - 1]^T$, by Fact 6, we have

$$\det(A + cd^T) = \det(A)(1 + d^T A^{-1} c) = (-4) \cdot (-1) = 4.$$

2. To illustrate Facts 8 and 9, let

$$A = \left[\begin{array}{cc|c} 3 & 1 & 1 \\ 1 & 5 & 1 \\ \hline 1 & 1 & 3 \end{array}\right] = \begin{bmatrix} X & Y \\ Y^* & Z \end{bmatrix}.$$

Note that A is positive definite and so Hadamard's inequality says that

$$\det A \leq 3 \cdot 5 \cdot 3 = 45;$$

in fact, $\det A = 36$. Fischer's inequality gives a smaller upper bound for the determinant:

$$\det A \leq \det X \det Z = 13 \cdot 3 = 39.$$

3. Consider the matrix

$$B = \begin{bmatrix} 1 & 2 & -2 \\ 4 & -1 & 1 \\ 0 & 1 & 1 \end{bmatrix}.$$

The first inequality about general matrices in Fact 8 applied to B gives

$$|\det B| \leq \sqrt{9 \cdot 18 \cdot 2} = 18.$$

As the rows of B are mutually orthogonal, we have that $|\det B| = 18$; in fact, $\det B = -18$.

16.5 Rank and Nullity Equalities and Inequalities

Let A be a matrix over a field F. Here we present relations among the fundamental subspaces of A and their dimensions. As general references consult, e.g., [HJ85] and [Mey00, Sec. 4.2, 4.4, 4.5] (even though the matrices discussed there are complex, most of the proofs remain valid for any field). Additional material on rank and nullity can also be found in Section 2.4.

Facts:

1. Let $A \in F^{m\times n}$. Then $\text{rank}(A) = \dim \text{range}A = \dim \text{range}A^T$.
   If $F = \mathbb{C}$, then $\text{rank}(A) = \dim \text{range}A^* = \dim \text{range}\overline{A}$.
2. Let $A \in F^{m\times n}$. Then $0 \le \text{rank}(A) \le \min\{m, n\}$.
3. If $A \in F^{m\times n}$, then for every submatrix B of A, $\text{rank}(A) \ge \text{rank}(B)$.
4. If $A \in \mathbb{C}^{m\times n}$, then $\text{range}A = (\ker A^*)^\perp$ and $\text{range}A^* = (\ker A)^\perp$.
5. If $A \in F^{m\times n}$ and $\text{rank}(A) = k$, then there exist $X \in F^{m\times k}$ and $Y \in F^{k\times n}$ such that $A = XY$.
6. Let $A, B \in F^{m\times n}$. Then $\text{rank}(A) = \text{rank}(B)$ if and only if there exist invertible matrices $X \in F^{m\times m}$ and $Y \in F^{n\times n}$ such that $B = XAY$.
7. (Dimension Theorem) Let $A \in F^{m\times n}$. Then
   $$\text{rank}(A) + \text{null}(A) = n \qquad \text{and} \qquad \text{rank}(A) + \text{null}(A^T) = m.$$
   If $F = \mathbb{C}$, then $\text{rank}(A) + \text{null}(A^*) = m$.
8. Let $A, B \in F^{m\times n}$. Then
   $$\text{rank}(A) - \text{rank}(B) \le \text{rank}(A + B) \le \text{rank}(A) + \text{rank}(B).$$
9. Let $A \in F^{m\times n}$, $B \in F^{m\times k}$, and $C = [A|B] \in F^{m\times(n+k)}$. Then
   (a) $\text{rank}(C) = \text{rank}(A) + \text{rank}(B) - \dim(\text{range}A \cap \text{range}B)$.
   (b) $\text{null}(C) = \text{null}(A) + \text{null}(B) + \dim(\text{range}A \cap \text{range}B)$.
10. Let $A \in F^{m\times n}$ and $B \in F^{n\times k}$. Then
    (a) $\text{rank}(AB) = \text{rank}(B) - \dim(\ker A \cap \text{range}B)$.
    (b) If $F = \mathbb{C}$, then $\text{rank}(AB) = \text{rank}(A) - \dim(\ker B^* \cap \text{range}A^*)$.
    (c) Multiplication of a matrix from the left or right by an invertible matrix leaves the rank unchanged.
    (d) $\text{null}(AB) = \text{null}(B) + \dim(\ker A \cap \text{range}B)$.
    (e) $\text{rank}(AB) \le \min\{\text{rank}(A), \text{rank}(B)\}$.
    (f) $\text{rank}(AB) \ge \text{rank}(A) + \text{rank}(B) - n$.
11. (Sylvester's law of nullity) Let $A, B \in \mathbb{C}^{n\times n}$. Then
    $$\begin{aligned}\max\{\text{null}(A), \text{null}(B)\} &\le \text{null}(AB)\\ &\le \text{null}(A) + \text{null}(B).\end{aligned}$$
    The above fact is valid *only* for square matrices.
12. (Frobenius inequality) Let $A \in F^{m\times n}$, $B \in F^{n\times k}$, and $C \in F^{k\times p}$. Then
    $$\text{rank}(AB) + \text{rank}(BC) \le \text{rank}(B) + \text{rank}(ABC).$$
13. Let $A \in \mathbb{C}^{m\times n}$. Then
    $$\text{rank}(A^*A) = \text{rank}(A) = \text{rank}(AA^*).$$
    In fact,
    $$\text{range}(A^*A) = \text{range}A^* \quad \text{and} \quad \text{range}A = \text{range}(AA^*),$$
    as well as
    $$\ker(A^*A) = \ker A \quad \text{and} \quad \ker(AA^*) = \ker A^*.$$

14. Let $A \in F^{m\times n}$ and $B \in F^{k\times p}$. The rank of their direct sum is
$$\operatorname{rank}(A \oplus B) = \operatorname{rank}\begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix} = \operatorname{rank}(A) + \operatorname{rank}(B).$$
15. Let $A = [a_{ij}] \in F^{m\times n}$ and $B \in F^{k\times p}$. The rank of the Kronecker product $A \otimes B = [a_{ij}B] \in F^{mk\times np}$ is
$$\operatorname{rank}(A \otimes B) = \operatorname{rank}(A)\operatorname{rank}(B).$$
16. Let $A = [a_{ij}] \in F^{m\times n}$ and $B = [b_{ij}] \in F^{m\times n}$. The rank of the Hadamard product $A \circ B = [a_{ij}b_{ij}] \in F^{m\times n}$ satisfies
$$\operatorname{rank}(A \circ B) \leq \operatorname{rank}(A)\operatorname{rank}(B).$$

Examples:

1. Consider the matrices
$$A = \begin{bmatrix} 1 & -1 & 1 \\ 2 & -1 & 0 \\ 3 & -2 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 2 & 3 & 4 \\ 0 & 0 & -1 \\ 2 & 1 & 2 \end{bmatrix}, \quad \text{and} \quad C = \begin{bmatrix} 1 & 2 & -1 & 1 \\ 1 & 2 & -1 & 1 \\ 2 & 4 & -2 & 2 \end{bmatrix}.$$
We have that
$$\operatorname{rank}(A) = 2, \quad \operatorname{rank}(B) = 3, \quad \operatorname{rank}(C) = 1, \quad \operatorname{rank}(A+B) = 3,$$
$$\operatorname{rank}(AB) = 2, \quad \operatorname{rank}(BC) = 1, \quad \operatorname{rank}(ABC) = 1.$$

- As a consequence of Fact 7, we have
$$\operatorname{null}(A) = 3-2 = 1, \quad \operatorname{null}(B) = 3-3 = 0, \quad \operatorname{null}(C) = 4-1 = 3,$$
$$\operatorname{null}(A+B) = 3-3 = 0, \quad \operatorname{null}(AB) = 3-2 = 1,$$
$$\operatorname{null}(BC) = 3-1 = 2, \quad \operatorname{null}(ABC) = 4-1 = 3.$$
- Fact 8 states that
$$-1 = 2-3 = \operatorname{rank}(A) - \operatorname{rank}(B) \leq \operatorname{rank}(A+B) = 0 \leq \operatorname{rank}(A) + \operatorname{rank}(B) = 5.$$
- Since $\operatorname{range}A \cap \operatorname{range}B = \operatorname{range}A$, Fact 9 states that
$$\operatorname{rank}([A|B]) = \operatorname{rank}(A) + \operatorname{rank}(B) - \dim(\operatorname{range}A \cap \operatorname{range}B) = 2+3-2 = 3,$$
$$\operatorname{null}([A|B]) = \operatorname{null}(A) + \operatorname{null}(B) + \dim(\operatorname{range}A \cap \operatorname{range}B) = 1+0+2 = 3.$$
- Since $\ker A \cap \operatorname{range}B = \ker A$, Fact 10 states that
$$2 = \operatorname{rank}(AB) = \operatorname{rank}(B) - \dim(\ker A \cap \operatorname{range}B) = 3-1 = 2.$$
$$2 = \operatorname{rank}(AB) \leq \min\{\operatorname{rank}(A), \operatorname{rank}(B)\} = 2.$$
$$2 = \operatorname{rank}(AB) \geq \operatorname{rank}(A) + \operatorname{rank}(B) - n = 2+3-3 = 2.$$
- Fact 11 states that
$$1 = \max\{\operatorname{null}(A), \operatorname{null}(B)\} \leq \operatorname{null}(AB) = 1$$
$$\leq \operatorname{Null}(A) + \operatorname{null}(B) = 1.$$

Fact 11 can fail for nonsquare matrices. For example, if

$$D = [1 \quad 1],$$

then

$$1 = \max\{\text{null}(D), \text{null}(D^T)\} \not\leq \text{null}(DD^T) = 0.$$

- Fact 12 states that

$$3 = \text{rank}(AB) + \text{rank}(BC) \leq \text{rank}(B) + \text{rank}(ABC) = 4.$$

16.6 Useful Identities for the Inverse

This section presents facts and formulas related to inversion of matrices.

Facts:

1. [Oue81, (1.9)], [HJ85, p. 18] Recall that $A/A[\alpha]$ denotes the Schur complement of the principal submatrix $A[\alpha]$ in A. (See Section 4.2, Section 11.3, and Chapter 12.) If $A \in F^{n\times n}$ is partitioned in blocks as

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix},$$

where A_{11} and A_{22} are square matrices, then, provided that A, A_{11}, and A_{22} are invertible, we have that the Schur complements A/A_{11} and A/A_{22} are invertible and

$$A^{-1} = \begin{bmatrix} (A/A_{22})^{-1} & -A_{11}^{-1}A_{12}(A/A_{11})^{-1} \\ -(A/A_{11})^{-1}A_{21}A_{11}^{-1} & (A/A_{11})^{-1} \end{bmatrix}.$$

More generally, given an invertible $A \in F^{n\times n}$ and $\alpha \subseteq \{1, 2, \ldots, n\}$ such that $A[\alpha]$ and $A(\alpha)$ are invertible, A^{-1} is obtained from A by replacing

   (a) $A[\alpha]$ by $(A/A(\alpha))^{-1}$,
   (b) $A[\alpha, \alpha^c]$ by $-A[\alpha]^{-1}A[\alpha, \alpha^c](A/A[\alpha])^{-1}$,
   (c) $A[\alpha^c, \alpha]$ by $-(A/A[\alpha])^{-1}A[\alpha^c, \alpha]A[\alpha]^{-1}$, and
   (d) $A(\alpha)$ by $(A/A[\alpha])^{-1}$.

2. [HJ85, pp. 18–19] Let $A \in F^{n\times n}$, $X \in F^{n\times r}$, $R \in F^{r\times r}$, and $Y \in F^{r\times n}$. Let $B = A + XRY$. Suppose that A, B, and R are invertible. Then

$$B^{-1} = (A + XRY)^{-1} = A^{-1} - A^{-1}X(R^{-1} + YA^{-1}X)^{-1}YA^{-1}.$$

3. (Sherman–Morrison) Let $A \in F^{n\times n}$, $x, y \in F^n$. Let $B = A + xy^T$. Suppose that A and B are invertible. Then, if $y^TA^{-1}x \neq -1$,

$$B^{-1} = (A + xy^T)^{-1} = A^{-1} - \frac{1}{1 + y^TA^{-1}x}A^{-1}xy^TA^{-1}.$$

In particular, if $y^Tx \neq -1$, then

$$(I + xy^T)^{-1} = I - \frac{1}{1 + y^Tx}xy^T.$$

4. Let $A \in F^{n\times n}$. Then the adjugate of A (see Section 4.2) satisfies
$$(\mathrm{adj}A)A = A(\mathrm{adj}A) = (\det A)I.$$
If A is invertible, then
$$A^{-1} = \frac{1}{\det A}\mathrm{adj}A.$$
5. Let $A \in F^{n\times n}$ be invertible and let its characteristic polynomial be $p_A(x) = x^n + a_{n-1}x^{n-1} + a_{n-2}x^{n-2} + \cdots + a_1x + a_0$. Then,
$$A^{-1} = \frac{(-1)^{n+1}}{\det A}(A^{n+1} + a_1A^n + a_2A^{n-1} + \cdots + a_{n-1}A).$$
6. [Mey00, Sec. 7.10, p. 618] Let $A \in \mathbb{C}^{n\times n}$. The following four statements are equivalent:
   - The **Neumann series**, $I + A + A^2 + \ldots$, converges.
   - $(I - A)^{-1}$ exists and $(I - A)^{-1} = \sum\limits_{k=0}^{\infty} A^k$.
   - $\rho(A) < 1$.
   - $\lim\limits_{k\to\infty} A^k = 0$.

Examples:

1. Consider the partitioned matrix
$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = \left[\begin{array}{rr|r} 1 & 3 & -1 \\ 0 & 2 & 1 \\ \hline -1 & -1 & 1 \end{array}\right].$$
Since
$$(A/A_{22})^{-1} = \begin{bmatrix} 0 & 2 \\ 1 & 3 \end{bmatrix}^{-1} = \begin{bmatrix} -1.5 & 1 \\ 0.5 & 0 \end{bmatrix} \quad \text{and} \quad (A/A_{11})^{-1} = (-1)^{-1} = -1,$$
by Fact 1, we have
$$A^{-1} = \begin{bmatrix} (A/A_{22})^{-1} & -A_{11}^{-1}A_{12}(A/A_{11})^{-1} \\ -(A/A_{11})^{-1}A_{21}A_{11}^{-1} & (A/A_{11})^{-1} \end{bmatrix} = \left[\begin{array}{rr|r} -1.5 & 1 & -2.5 \\ 0.5 & 0 & 0.5 \\ \hline -1 & 1 & -1 \end{array}\right].$$
2. To illustrate Fact 3, consider the invertible matrix
$$A = \begin{bmatrix} 1 & i & -1 \\ 1 & 0 & 1 \\ -2i & 1 & -2 \end{bmatrix}$$
and the vectors $x = y = [1\,1\,1]^T$. We have that
$$A^{-1} = \begin{bmatrix} 0.5i & 1 + 0.5i & 0.5 \\ -1 - i & -1 + i & i \\ -0.5i & -0.5i & -0.5 \end{bmatrix}.$$
Adding xy^T to A amounts to adding 1 to each entry of A; since
$$1 + y^TA^{-1}x = i \neq 0,$$

the resulting matrix is invertible and its inverse is given by

$$\begin{aligned}(A+xy^T)^{-1} &= A^{-1} - \frac{1}{i}A^{-1}xy^TA^{-1} \\ &= \begin{bmatrix} 2.5 & -0.5-0.5i & -1-i \\ -2+2i & 1 & 2 \\ -1.5-i & 0.5+0.5i & i \end{bmatrix}.\end{aligned}$$

3. Consider the matrix

$$A = \begin{bmatrix} -1 & 1 & -1 \\ 1 & -1 & 3 \\ 1 & -1 & 2 \end{bmatrix}.$$

Since $A^3 = 0$, A is a nilpotent matrix and, thus, all its eigenvalues equal 0. That is, $\rho(A) = 0 < 1$. As a consequence of Fact 6, $I - A$ is invertible and

$$(I-A)^{-1} = I + A + A^2 = \begin{bmatrix} 1 & 0 & 1 \\ 2 & -1 & 5 \\ 1 & -1 & 3 \end{bmatrix}.$$

Matrix functions are used in many areas of linear algebra and arise in numerous applications in science and engineering. The most common matrix function is the matrix inverse; it is not treated specifically in this chapter, but is covered in Section 1.5 and Section 51.3. This chapter is concerned with general matrix functions as well as specific cases such as matrix square roots, trigonometric functions, and the exponential and logarithmic functions.

The specific functions just mentioned can all be defined via power series or as the solution of nonlinear systems. For example, $\cos(A) = I - A^2/2! + A^4/4! - \cdots$. However, a general theory exists from which a number of properties possessed by all matrix functions can be deduced and which suggests computational methods. This chapter treats general theory, then specific functions, and finally outlines computational methods. More details of all aspects of this chapter can be found in [Hig08].

17.1 General Theory

Definitions:

A function of a matrix can be defined in several ways, of which the following three are the most generally useful.

- *Jordan canonical form definition.* Let $A \in \mathbb{C}^{n\times n}$ have the Jordan canonical form $Z^{-1}AZ = J_A = \operatorname{diag}\bigl(J_1(\lambda_1), J_2(\lambda_2), \ldots, J_p(\lambda_p)\bigr)$, where Z is nonsingular,

$$J_k(\lambda_k) = \begin{bmatrix} \lambda_k & 1 & & \\ & \lambda_k & \ddots & \\ & & \ddots & 1 \\ & & & \lambda_k \end{bmatrix} \in \mathbb{C}^{m_k\times m_k}, \qquad (17.1)$$

and $m_1 + m_2 + \cdots + m_p = n$. Then

$$f(A) := Zf(J_A)Z^{-1} = Z\,\mathrm{diag}(f(J_k(\lambda_k)))Z^{-1}, \tag{17.2}$$

where

$$f(J_k(\lambda_k)) := \begin{bmatrix} f(\lambda_k) & f'(\lambda_k) & \dots & \dfrac{f^{(m_k-1)}(\lambda_k)}{(m_k-1)!} \\ & f(\lambda_k) & \ddots & \vdots \\ & & \ddots & f'(\lambda_k) \\ & & & f(\lambda_k) \end{bmatrix}. \tag{17.3}$$

- *Polynomial interpolation definition.* Denote by $\lambda_1, \dots, \lambda_s$ the distinct eigenvalues of A and let n_i be the **index** of λ_i, that is, the order of the largest Jordan block in which λ_i appears. Then $f(A) := r(A)$, where r is the unique Hermite interpolating polynomial of degree less than $\sum_{i=1}^{s} n_i$ that satisfies the interpolation conditions

$$r^{(j)}(\lambda_i) = f^{(j)}(\lambda_i), \qquad j = 0{:}\, n_i - 1, \quad i = 1{:}\, s. \tag{17.4}$$

Note that in both these definitions the derivatives in (17.4) must exist in order for $f(A)$ to be defined. The function f is said to be **defined on the spectrum of** A if all the derivatives in (17.4) exist.

- *Cauchy integral definition.*

$$f(A) := \frac{1}{2\pi i} \int_\Gamma f(z)(zI - A)^{-1}\, dz, \tag{17.5}$$

where f is analytic inside a closed contour Γ that encloses $\sigma(A)$.

When the function f is multivalued and A has a repeated eigenvalue occurring in more than one Jordan block (i.e., A is derogatory), the Jordan canonical form definition has more than one interpretation. Usually, for each occurrence of an eigenvalue in different Jordan blocks the same branch is taken for f and its derivatives. This gives a **primary matrix function**. If different branches are taken for the same eigenvalue in two different Jordan blocks, then a **nonprimary matrix function** is obtained. A nonprimary matrix function is not expressible as a polynomial in the matrix, and if such a function is obtained from the Jordan canonical form definition (17.2), then it depends on the matrix Z. In most applications it is primary matrix functions that are of interest. For the rest of this section $f(A)$ is assumed to be a primary matrix function, unless otherwise stated.

Facts:

Proofs of the facts in this section can be found in one or more of [Hig08, Chaps. 1, 4], [HJ91], or [LT85], unless otherwise stated.

1. The Jordan canonical form and polynomial interpolation definitions are equivalent. Both definitions are equivalent to the Cauchy integral definition when f is analytic.
2. $f(A)$ is a polynomial in A and the coefficients of the polynomial depend on A.
3. $f(A)$ commutes with A.
4. $f(A^T) = f(A)^T$.
5. For any nonsingular X, $f(XAX^{-1}) = Xf(A)X^{-1}$.
6. If A is diagonalizable, with $Z^{-1}AZ = D = \mathrm{diag}(d_1, d_2, \dots, d_n)$, then $f(A) = Zf(D)Z^{-1} = Z\,\mathrm{diag}(f(d_1), f(d_2), \dots, f(d_n))Z^{-1}$.
7. $f\big(\mathrm{diag}(A_1, A_2, \dots, A_m)\big) = \mathrm{diag}(f(A_1), f(A_2), \dots, f(A_m))$.

8. Let f and g be functions defined on the spectrum of A.
    (a) If $h(t) = f(t) + g(t)$, then $h(A) = f(A) + g(A)$.
    (b) If $h(t) = f(t)g(t)$, then $h(A) = f(A)g(A)$.
9. Let $G(u_1, \dots, u_t)$ be a polynomial in $u_1, \dots, u_t$ and let $f_1, \dots, f_t$ be functions defined on the spectrum of A. If $g(\lambda) = G(f_1(\lambda), \dots, f_t(\lambda))$ takes zero values on the spectrum of A, then $g(A) = G(f_1(A), \dots, f_t(A)) = 0$. For example, $\sin^2(A) + \cos^2(A) = I$, $(A^{1/p})^p = A$, and $e^{iA} = \cos A + i \sin A$.
10. Suppose f has a Taylor series expansion

$$f(z) = \sum_{k=0}^{\infty} a_k (z - \alpha)^k \qquad \left(a_k = \frac{f^{(k)}(\alpha)}{k!} \right)$$

with radius of convergence r. If $A \in \mathbb{C}^{n\times n}$, then $f(A)$ is defined and is given by

$$f(A) = \sum_{k=0}^{\infty} a_k (A - \alpha I)^k$$

if and only if each of the distinct eigenvalues $\lambda_1, \dots, \lambda_s$ of A satisfies one of the conditions:

    (a) $|\lambda_i - \alpha| < r$.
    (b) $|\lambda_i - \alpha| = r$ and the series for $f^{n_i - 1}(\lambda)$, where n_i is the index of λ_i, is convergent at the point $\lambda = \lambda_i$, $i = 1\colon s$.

11. [Dav73], [Des63], [GVL96, Theorem 11.1.3]. Let $T \in \mathbb{C}^{n\times n}$ be upper triangular and suppose that f is defined on the spectrum of T. Then $F = f(T)$ is upper triangular with $f_{ii} = f(t_{ii})$ and

$$f_{ij} = \sum_{(s_0,\dots,s_k)\in S_{ij}} t_{s_0,s_1} t_{s_1,s_2} \dots t_{s_{k-1},s_k} f[\lambda_{s_0}, \dots, \lambda_{s_k}],$$

where $\lambda_i = t_{ii}$, S_{ij} is the set of all strictly increasing sequences of integers that start at i and end at j, and $f[\lambda_{s_0}, \dots, \lambda_{s_k}]$ is the kth order divided difference of f at $\lambda_{s_0}, \dots, \lambda_{s_k}$.

Examples:

1. For $\lambda_1 \neq \lambda_2$,

$$f\left(\begin{bmatrix} \lambda_1 & \alpha \\ 0 & \lambda_2 \end{bmatrix}\right) = \begin{bmatrix} f(\lambda_1) & \alpha \dfrac{f(\lambda_2) - f(\lambda_1)}{\lambda_2 - \lambda_1} \\ 0 & f(\lambda_2) \end{bmatrix}.$$

For $\lambda_1 = \lambda_2 = \lambda$,

$$f\left(\begin{bmatrix} \lambda & \alpha \\ 0 & \lambda \end{bmatrix}\right) = \begin{bmatrix} f(\lambda) & \alpha f'(\lambda) \\ 0 & f(\lambda) \end{bmatrix}.$$

2. Compute e^A for the matrix

$$A = \begin{bmatrix} -7 & -4 & -3 \\ 10 & 6 & 4 \\ 6 & 3 & 3 \end{bmatrix}.$$

We have $A = XJ_AX^{-1}$, where $J_A = [0] \oplus \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$ and

$$X = \begin{bmatrix} 1 & -1 & -1 \\ -1 & 2 & 0 \\ -1 & 0 & 3 \end{bmatrix}.$$

Hence, using the Jordan canonical form definition, we have

$$\begin{aligned} e^A &= Xe_A^J X^{-1} = X\big([1] \oplus \left[\begin{smallmatrix} e & e \\ 0 & e \end{smallmatrix}\right]\big)X^{-1} \\ &= \begin{bmatrix} 1 & -1 & -1 \\ -1 & 2 & 0 \\ -1 & 0 & 3 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & e & e \\ 0 & 0 & e \end{bmatrix} \begin{bmatrix} 6 & 3 & 2 \\ 2 & 2 & 1 \\ 2 & 1 & 1 \end{bmatrix} \\ &= \begin{bmatrix} 6-7e & 3-4e & 2-3e \\ -6+10e & -3+6e & -2+4e \\ -6+6e & -3+3e & -2+3e \end{bmatrix}. \end{aligned}$$

3. Compute $\sqrt{A}$ for the matrix in Example 2. To obtain the square root, we use the polynomial interpolation definition. The eigenvalues of A are 0 and 1, with indices 1 and 2, respectively. The unique polynomial r of degree at most 2 satisfying the interpolation conditions $r(0) = f(0)$, $r(1) = f(1)$, $r'(1) = f'(1)$ is

$$r(t) = f(0)(t-1)^2 + t(2-t)f(1) + t(t-1)f'(1).$$

With $f(t) = t^{1/2}$, taking the positive square root, we have $r(t) = t(2-t) + t(t-1)/2$ and, therefore,

$$A^{1/2} = A(2I - A) + A(A - I)/2 = \begin{bmatrix} -6 & -3.5 & -2.5 \\ 8 & 5 & 3 \\ 6 & 3 & 3 \end{bmatrix}.$$

4. Consider the $m_k \times m_k$ Jordan block $J_k(\lambda_k)$ in (17.1). The polynomial satisfying the interpolation conditions (17.4) is

$$r(t) = f(\lambda_k) + (t-\lambda_k)f'(\lambda_k) + \frac{(t-\lambda_k)^2}{2!}f''(\lambda_k) + \cdots + \frac{(t-\lambda_k)^{m_k-1}}{(m_k-1)!}f^{(m_k-1)}(\lambda_k),$$

which, of course, is the first m_k terms of the Taylor series of f about λ_k. Hence, from the polynomial interpolation definition,

$$\begin{aligned} f(J_k(\lambda_k)) &= r(J_k(\lambda_k)) \\ &= f(\lambda_k)I + (J_k(\lambda_k) - \lambda_k I)f'(\lambda_k) + \frac{(J_k(\lambda_k) - \lambda_k I)^2}{2!}f''(\lambda_k) + \cdots \\ &\quad + \frac{(J_k(\lambda_k) - \lambda_k I)^{m_k-1}}{(m_k-1)!}f^{(m_k-1)}(\lambda_k). \end{aligned}$$

The matrix $(J_k(\lambda_k) - \lambda_k I)^j$ is zero except for 1s on the jth superdiagonal. This expression for $f(J_k(\lambda_k))$ is, therefore, equal to that in (17.3), confirming the consistency of the first two definitions of $f(A)$.

17.2 Matrix Exponential

Definitions:

The **exponential** of $A \in \mathbb{C}^{n\times n}$, written e^A or $\exp(A)$, is defined by

$$e^A = I + A + \frac{A^2}{2!} + \cdots + \frac{A^k}{k!} + \cdots.$$

Facts:

Proofs of the facts in this section can be found in one or more of [Hig08, Chaps. 1, 10], [HJ91], or [LT85].

1. $e^{(A+B)t} = e^{At}e^{Bt}$ holds for all t if and only if $AB = BA$.
2. The differential equation in $n \times n$ matrices
$$\frac{dY}{dt} = AY, \qquad Y(0) = C, \qquad A, Y \in \mathbb{C}^{n\times n},$$
has solution $Y(t) = e^{At}C$.
3. The differential equation in $n \times n$ matrices
$$\frac{dY}{dt} = AY + YB, \qquad Y(0) = C, \qquad A, B, Y \in \mathbb{C}^{n\times n},$$
has solution $Y(t) = e^{At}Ce^{Bt}$.
4. $A \in \mathbb{C}^{n\times n}$ is unitary if and only if it can be written $A = e^{iH}$, where H is Hermitian. In this representation H can be taken to be Hermitian positive definite.
5. $A \in \mathbb{R}^{n\times n}$ is orthogonal with $\det(A) = 1$ if and only if $A = e^S$ with $S \in \mathbb{R}^{n\times n}$ skew-symmetric.

Examples:

1. Fact 5 is illustrated by the matrix
$$A = \begin{bmatrix} 0 & \alpha \\ -\alpha & 0 \end{bmatrix},$$
for which
$$e^A = \begin{bmatrix} \cos\alpha & \sin\alpha \\ -\sin\alpha & \cos\alpha \end{bmatrix}.$$

17.3 Matrix Logarithm

Definitions:

Let $A \in \mathbb{C}^{n\times n}$. Any X such that $e^X = A$ is a **logarithm** of A.

Facts:

Proofs of the facts in this section can be found in one or more of [Hig08, Chaps. 1, 11], [HJ91], or [LT85].

1. If A has no eigenvalues on $\mathbb{R}_0^-$, then there is a unique logarithm X of A all of whose eigenvalues lie in the strip $\{\, z : -\pi < \mathrm{Im}(z) < \pi \,\}$. This is the **principal logarithm** of A and is written $X = \log A$. If A is real, then $\log A$ is real.

2. If $\rho(A) < 1$,
$$\log(I + A) = A - \frac{A^2}{2} + \frac{A^3}{3} - \frac{A^4}{4} + \cdots.$$
3. $A \in \mathbb{R}^{n\times n}$ has a real logarithm if and only if A is nonsingular and A has an even number of Jordan blocks of each size for every negative eigenvalue.
4. $\exp(\log A) = A$ holds when log is defined on the spectrum of $A \in \mathbb{C}^{n\times n}$. But $\log(\exp(A)) = A$ holds if and only if every eigenvalue λ_i of A satisfies $|\operatorname{Im}\lambda_i| < \pi$.
5. If $A \in \mathbb{C}^{n\times n}$ is nonsingular, then $\det(A) = \exp(\operatorname{tr}(\log A))$, where $\log A$ is any logarithm of A.

Examples:

1. For the matrix
$$A = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 \\ 0 & 0 & 1 & 3 \\ 0 & 0 & 0 & 1 \end{bmatrix},$$
we have
$$\log(A) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

17.4 Matrix Sine and Cosine

Definitions:

The **sine** and **cosine** of $A \in \mathbb{C}^{n\times n}$ are defined by

$$\cos(A) = I - \frac{A^2}{2!} + \cdots + \frac{(-1)^k}{(2k)!}A^{2k} + \cdots,$$
$$\sin(A) = A - \frac{A^3}{3!} + \cdots + \frac{(-1)^k}{(2k+1)!}A^{2k+1} + \cdots.$$

Facts:

Proofs of the facts in this section can be found in one or more of [Hig08, Chaps. 1, 12], [HJ91], or [LT85].

1. $\cos(2A) = 2\cos^2(A) - I$.
2. $\sin(2A) = 2\sin(A)\cos(A)$.
3. $\cos^2(A) + \sin^2(A) = I$.
4. The differential equation
$$\frac{d^2y}{dt^2} + Ay = 0, \qquad y(0) = y_0, \quad y'(0) = y_0'$$
has solution
$$y(t) = \cos(\sqrt{A}t)y_0 + \left(\sqrt{A}\right)^{-1}\sin(\sqrt{A}t)y_0',$$
where $\sqrt{A}$ denotes any square root of A.

Examples:

1. For
$$A = \begin{bmatrix} 0 & i\,\alpha \\ i\,\alpha & 0 \end{bmatrix},$$
we have
$$e^A = \begin{bmatrix} \cos\alpha & i\sin\alpha \\ i\sin\alpha & \cos\alpha \end{bmatrix}.$$
2. For
$$A = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & -1 & -2 & -3 \\ 0 & 0 & 1 & 3 \\ 0 & 0 & 0 & -1 \end{bmatrix},$$
we have
$$\cos(A) = \cos(1)I, \qquad \sin(A) = \begin{bmatrix} \sin(1) & \sin(1) & \sin(1) & \sin(1) \\ 0 & -\sin(1) & -2\sin(1) & -3\sin(1) \\ 0 & 0 & \sin(1) & 3\sin(1) \\ 0 & 0 & 0 & -\sin(1) \end{bmatrix},$$
and $\sin^2(A) = \sin(1)^2 I$, so $\cos(A)^2 + \sin(A)^2 = I$.

17.5 Matrix Square Root

Definitions:

Let $A \in \mathbb{C}^{n\times n}$. Any X such that $X^2 = A$ is a **square root** of A.

Facts:

Proofs of the facts in this section can be found in one or more of [Hig08, Chaps. 1, 6], [HJ91], or [LT85], unless otherwise stated.

1. If $A \in \mathbb{C}^{n\times n}$ has no eigenvalues on $\mathbb{R}_0^-$ (the closed negative real axis), then there is a unique square root X of A all of whose eigenvalues lie in the open right half-plane, and it is a primary matrix function of A. This is the **principal square root** of A and is written $X = A^{1/2}$. If A is real, then $A^{1/2}$ is real. An integral representation is
$$A^{1/2} = \frac{2}{\pi} A \int_0^\infty (t^2 I + A)^{-1}\, dt.$$
2. A positive (semi)definite matrix $A \in \mathbb{C}^{n\times n}$ has a unique positive (semi)definite square root. (See also Section 9.4.)
3. [CL74] A singular matrix $A \in \mathbb{C}^{n\times n}$ may or may not have a square root. A necessary and sufficient condition for A to have a square root is that in the "ascent sequence" of integers d_1, d_2, … defined by
$$d_i = \dim(\ker(A^i)) - \dim(\ker(A^{i-1})),$$
no two terms are the same odd integer.

4. $A \in \mathbb{R}^{n\times n}$ has a real square root if and only if A satisfies the condition in the previous fact and A has an even number of Jordan blocks of each size for every negative eigenvalue.
5. The $n \times n$ identity matrix I_n has 2^n diagonal square roots $\mathrm{diag}(\pm 1)$. Only two of these are primary matrix functions, namely I and $-I$. Nondiagonal but symmetric nonprimary square roots of I_n include any Householder matrix $I - 2\mathbf{v}\mathbf{v}^T/(\mathbf{v}^T\mathbf{v})$ ($\mathbf{v} \neq 0$) and the identity matrix with its columns in reverse order. Nonsymmetric square roots of I_n are easily constructed in the form XDX^{-1}, where X is nonsingular but nonorthogonal and $D = \mathrm{diag}(\pm 1) \neq \pm I$.

Examples:

1. The Jordan block $\left[\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right]$ has no square root. The matrix

$$\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

has ascent sequence $2, 1, 0, \ldots$ and so does have a square root — for example, the matrix

$$\begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}.$$

17.6 Arbitrary Matrix Power

Definitions:

For a real $s \in \mathbb{R}$ and a matrix $A \in \mathbb{C}^{n\times n}$ with no eigenvalues on $\mathbb{R}_0^-$, $A^s = e^{s \log A}$, where log is the principal logarithm (see Section 17.3).

Facts:

1. [Hig08, pp. 174, 187] For $0 < s < 1$,

$$A^s = \frac{\sin(s\pi)}{s\pi} A \int_0^\infty (t^{1/s} I + A)^{-1}\, dt. \tag{17.6}$$

2. For $s = 1/p$, with p a positive integer, A^s reduces to the **principal pth root of A**, defined as the unique matrix X such that $X^p = A$ and all the eigenvalues of X lie in the segment $\{\, z : -\pi/p < \arg(z) < \pi/p \,\}$.
3. [HL11a] Matrix pth roots arise, for example, in the context of Markov chains, since if A is a transition matrix (a stochastic matrix) for a given time period, $A^{1/p}$ is a transition matrix for one pth of that time period as long as it is stochastic. However, stochasticity is not always preserved under the taking of pth roots, and few sufficient conditions for its preservation are available. One result is that $A^{1/p}$ is stochastic for all positive integers p if A is the inverse of an M-matrix (see Example 2).

Examples:

1. For the matrix

$$A = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 \\ -4 & -3 & -2 & -1 & 0 \\ 6 & 3 & 1 & 0 & 0 \\ -4 & -1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \end{bmatrix}$$

which is `pascal(5,2)` in MATLAB, we have

$$A^2 = \begin{bmatrix} 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & -1 & -4 \\ 0 & 0 & 1 & 3 & 6 \\ 0 & -1 & -2 & -3 & -4 \\ 1 & 1 & 1 & 1 & 1 \end{bmatrix}$$

and $A^3 = I$. Thus, A is a cube root of I, but it is not the principal cube root as the negative trace of A implies that not all its eigenvalues lie in the open right half-plane.

2. The lower triangular matrix

$$A = \begin{bmatrix} 1 & & & \\ \frac{1}{2} & \frac{1}{2} & & \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} & \\ \frac{1}{4} & \frac{1}{4} & \frac{1}{4} & \frac{1}{4} \end{bmatrix}$$

is the inverse of an M-matrix and so by Fact 3 has stochastic pth roots for all p; in particular,

$$A^{1/2} = \begin{bmatrix} 1.000 & & & \\ 0.293 & 0.707 & & \\ 0.163 & 0.260 & 0.577 & \\ 0.111 & 0.157 & 0.232 & 0.500 \end{bmatrix}, \qquad A^{1/4} = \begin{bmatrix} 1.000 & & & \\ 0.206 & 0.794 & & \\ 0.106 & 0.201 & 0.693 & \\ 0.069 & 0.111 & 0.190 & 0.630 \end{bmatrix}$$

(shown to three decimal places) are stochastic square and fourth roots.

17.7 Matrix Sign Function

Definitions:

If $A = ZJ_AZ^{-1} \in \mathbb{C}^{n\times n}$ is a Jordan canonical form arranged so that

$$J_A = \begin{bmatrix} J_A^{(1)} & 0 \\ 0 & J_A^{(2)} \end{bmatrix},$$

where the eigenvalues of $J_A^{(1)} \in \mathbb{C}^{p\times p}$ lie in the open left half-plane and those of $J_A^{(2)} \in \mathbb{C}^{q\times q}$ lie in the open right half-plane, with $p + q = n$, then

$$\operatorname{sign}(A) = Z \begin{bmatrix} -I_p & 0 \\ 0 & I_q \end{bmatrix} Z^{-1}.$$

Alternative formulas are

$$\operatorname{sign}(A) = A(A^2)^{-1/2}, \tag{17.7}$$

$$\operatorname{sign}(A) = \frac{2}{\pi} A \int_0^\infty (t^2 I + A^2)^{-1}\, dt.$$

If A has any pure imaginary eigenvalues, then sign(A) is not defined.

Facts:

Proofs of the facts in this section can be found in [Hig08, Chap. 5].

Let $S = \operatorname{sign}(A)$ be defined. Then

1. $S^2 = I$ (S is involutory).
2. S is diagonalizable with eigenvalues ± 1.
3. $SA = AS$.
4. If A is real, then S is real.
5. If A is symmetric positive definite, then $\operatorname{sign}(A) = I$.

Examples:

1. For the matrix A in Example 17.4.2 we have $\operatorname{sign}(A) = A$, which follows from Eq. (17.7) and the fact that A is involutory.

17.8 Computational Methods for General Functions

Many methods have been proposed for evaluating matrix functions. Three general approaches of wide applicability are outlined here. They have in common that they do not require knowledge of Jordan structure and are suitable for computer implementation. More details of methods can be found in [HAM10].

1. *Polynomial and Rational Approximations*:

Polynomial approximations

$$p_m(X) = \sum_{k=0}^{m} b_k X^k, \qquad b_k \in \mathbb{C},\ X \in \mathbb{C}^{n\times n},$$

to matrix functions can be obtained by truncating or economizing a power series representation, or by constructing a best approximation (in some norm) of a given degree. How to most efficiently evaluate a polynomial at a matrix argument is a nontrivial question. Possibilities include Horner's method, explicit computation of the powers of the matrix, and a method of Paterson and Stockmeyer [Hig08, Sec. 4.2], [PS73], which is a combination of these two methods that requires fewer matrix multiplications.

Rational approximations $r_{mk}(X) = p_m(X)q_k(X)^{-1}$ are also widely used, particularly those arising from Padé approximation, which produces rationals matching as many terms of the Taylor series of the function at the origin as possible. The evaluation of rationals at matrix arguments needs careful consideration in order to find the best compromise between speed and accuracy. The main possibilities are

- Evaluating the numerator and denominator polynomials and then solving a multiple right-hand side linear system.
- Evaluating a continued fraction representation (in either top-down or bottom-up order).
- Evaluating a partial fraction representation.

Since polynomials and rationals are typically accurate over a limited range of matrices, practical methods involve a reduction stage prior to evaluating the polynomial or rational.

2. *Factorization Methods*:

Many methods are based on the property $f(XAX^{-1}) = Xf(A)X^{-1}$. If X can be found such that $B = XAX^{-1}$ has the property that $f(B)$ is easily evaluated, then an obvious method results. When A is diagonalizable, B can be taken to be diagonal, and evaluation of $f(B)$ is trivial. In finite precision arithmetic, though, this approach is reliable only if X is well conditioned, that is, if the condition number $\kappa(X) = \|X\|\|X^{-1}\|$ is not too large. Ideally, X will be unitary, so that in the 2-norm $\kappa_2(X) = 1$. For Hermitian A, or more generally normal A, the spectral decomposition $A = QDQ^*$ with Q unitary and D diagonal is always possible, and if this decomposition can be computed then the formula $f(A) = Qf(D)Q^*$ provides an excellent way of computing $f(A)$.

For general A, if X is restricted to be unitary then the furthest that A can be reduced is to Schur form: $A = QTQ^*$, where Q is unitary and T upper triangular. This decomposition is computed by the QR algorithm. Computing a function of a triangular matrix is an interesting problem. While Fact 17.1.11 gives an explicit formula for $F = f(T)$, the formula is not practically viable due to its exponential cost in n. Much more efficient is a recurrence of Parlett [Par76]. This is derived by starting with the observation that since F is representable as a polynomial in T, F is upper triangular, with diagonal elements $f(t_{ii})$. The elements in the strict upper triangle are determined by solving the equation $FT = TF$. Parlett's recurrence is:

Algorithm 1. Parlett's recurrence.

```
$f_{ii} = f(t_{ii}),\ i = 1\colon n$
for $j = 2\colon n$
    for $i = j-1\colon -1\colon 1$
        $f_{ij} = t_{ij} \dfrac{f_{ii} - f_{jj}}{t_{ii} - t_{jj}} + \left( \sum_{k=i+1}^{j-1} f_{ik} t_{kj} - t_{ik} f_{kj} \right) \Big/ (t_{ii} - t_{jj})$
    end
end
```

This recurrence can be evaluated in $2n^3/3$ operations. The recurrence breaks down when $t_{ii} = t_{jj}$ for some $i \neq j$. In this case, T can be regarded as a block matrix $T = (T_{ij})$, with square diagonal blocks, possibly of different sizes. T can be reordered so that no two diagonal blocks have an eigenvalue in common; reordering means applying a unitary similarity transformation to permute the diagonal elements while preserving triangularity. Then a block form of the recurrence can be employed. This requires the evaluation of the diagonal blocks $F_{ii} = f(T_{ii})$, where T_{ii} will typically be of small dimension. A general way to obtain F_{ii} is via a Taylor series. The use of the block Parlett recurrence in combination with a Schur decomposition represents the state of the art in evaluation of $f(A)$ for general functions [DH03].

3. *Iteration Methods*:

Several matrix functions f can be computed by iteration:

$$X_{k+1} = g(X_k), \qquad X_0 = A, \tag{17.8}$$

where, for reasons of computational cost, g is usually a polynomial or a rational function. Such an iteration might converge for all A for which f is defined, or just for a subset of such A. A standard means of deriving matrix iterations is to apply Newton's method to an algebraic equation satisfied by $f(A)$. The iterations most used in practice are quadratically convergent, but iterations with higher orders of convergence are known.

4. *Contour Integration*:

The Cauchy integral definition (17.5) provides a way to compute or approximate $f(A)$ via contour integration. While not suitable as a practical method for all functions or all matrices, this approach can be effective when numerical integration is preceded by a conformal mapping and done over a suitable contour using the repeated trapezium rule, whose high accuracy properties for periodic functions integrated over a whole period are beneficial [DH05], [HHT08].

17.9 Computational Methods for Specific Functions

Some methods specialized to particular functions are now outlined.

1. *Matrix Exponential*:

Numerous methods have been proposed for the matrix exponential, many of them of pedagogic interest only or of dubious numerical stability. Some of the more computationally useful methods are surveyed in [MV03]. Probably the best general-purpose method is the scaling and squaring method. In this method an integral power of 2, $\sigma = 2^s$ say, is chosen so that A/σ has norm not too far from 1. The exponential of the scaled matrix is approximated by an $[m/m]$ Padé approximant, $e^{A/2^s} \approx r_{mm}(A/2^s)$, and then s repeated squarings recover an approximation to e^A: $e^A \approx r_{mm}(A/2^s)^{2^s}$. Symmetries in the Padé approximant permit an efficient evaluation of $r_{mm}(A)$. The scaling and squaring method was originally developed in [MV78] and [War77], and it is the method employed by the MATLAB function expm. How best to choose σ and m is described in [AH09] and [Hig09].

2. *Matrix Logarithm*:

The (principal) matrix logarithm can be computed using an inverse scaling and squaring method based on the identity $\log A = 2^k \log A^{1/2^k}$, where A is assumed to have no eigenvalues on $\mathbb{R}_0^-$. Square roots are taken to make $\|A^{1/2^k} - I\|$ small enough that an $[m/m]$ Padé approximant approximates $\log A^{1/2^k}$ sufficiently accurately, for some suitable m. Then $\log A$ is recovered by multiplying by 2^k. To reduce the cost of computing the square roots and evaluating the Padé approximant, a Schur decomposition can be computed initially so that the method works with a triangular matrix. For details, see [AH12], [CHK01], [Hig01], or [KL89, App. A].

3. *Matrix Cosine and Sine*:

A method analogous to the scaling and squaring method for the exponential is the standard method for computing the matrix cosine. The idea is again to scale A to have norm not too far from 1 and then compute a Padé approximant. The difference is that the scaling is undone by repeated use of the double-angle formula $\cos(2A) = 2\cos^2 A - I$, rather than by repeated squaring. The sine function can be obtained as $\sin(A) = \cos(A - \frac{\pi}{2}I)$ [SB80], [Hig08, Chap. 12], [HS03], [HH05].

4. *Matrix Square Root*:

The most numerically reliable way to compute matrix square roots is via the Schur decomposition, $A = QTQ^*$ [BH83]. Rather than use the Parlett recurrence, a square root U of the upper triangular factor T can be computed by directly solving the equation $U^2 = T$. The choices of sign in the diagonal of U, $u_{ii} = \sqrt{t_{ii}}$, determine which square root is obtained. When A is real, the real Schur decomposition can be used to compute real square roots entirely in real arithmetic [Hig87].

Various iterations exist for computing the principal square root when A has no eigenvalues on $\mathbb{R}_0^-$. The basic Newton iteration,

$$X_{k+1} = \frac{1}{2}(X_k + X_k^{-1}A), \qquad X_0 = A, \tag{17.9}$$

is quadratically convergent, but is numerically unstable unless A is extremely well conditioned and its use is not recommended [Hig86]. Stable alternatives include the Denman–Beavers iteration [DB76]

$$X_{k+1} = \frac{1}{2}\left(X_k + Y_k^{-1}\right), \qquad X_0 = A,$$

$$Y_{k+1} = \frac{1}{2}\left(Y_k + X_k^{-1}\right), \qquad Y_0 = I,$$

for which $\lim_{k\to\infty} X_k = A^{1/2}$ and $\lim_{k\to\infty} Y_k = A^{-1/2}$, and the Meini iteration [Mei04]

$$\begin{aligned} Y_{k+1} &= -Y_k Z_k^{-1} Y_k, & Y_0 &= I - A, \\ Z_{k+1} &= Z_k + 2Y_{k+1}, & Z_0 &= 2(I + A), \end{aligned}$$

for which $Y_k \to 0$ and $Z_k \to 4A^{1/2}$. Both of these iterations are mathematically equivalent to Eq. (17.9) and, hence, are quadratically convergent.

An iteration not involving matrix inverses is the Schulz iteration

$$\begin{aligned} Y_{k+1} &= \tfrac{1}{2} Y_k (3I - Z_k Y_k), & Y_0 &= A, \\ Z_{k+1} &= \tfrac{1}{2}(3I - Z_k Y_k) Z_k, & Z_0 &= I, \end{aligned}$$

for which $Y_k \to A^{1/2}$ and $Z_k \to A^{-1/2}$ quadratically provided that $\|\operatorname{diag}(A-I, A-I)\| < 1$, where the norm is any consistent matrix norm [Hig97].

5. *Arbitrary Matrix Power*:

A matrix power A^s with $s \in \mathbb{R}$ can be computed by the Schur–Padé algorithm [HL11b], which exploits the relation $A^s = (A^{1/2^k})^{s \cdot 2^k}$. It reduces A to Schur form, computes k square roots of the triangular matrix T so that $T^{1/2^k}$ is sufficiently close to I, evaluates a Padé approximant to the function $(1-x)^s$, then squares k times and undoes the Schur transformation. This approach is superior in practice to evaluating $A^s = e^{s \log A}$ using methods for exp and log.

For pth roots, several methods are available. The Schur method for square roots has been extended to pth roots [Smi03]. Various other methods are available [BHM05]. For the (inverse) Newton iteration, convergence conditions are nontrivial [BHM05], [Ian06], and, as in the square root case, coupled iterations help to ensure numerical stability. By combining a Newton iteration with a Schur decomposition, an effective algorithm that can compute either $A^{1/p}$ or $A^{-1/p}$ can be obtained [GH06].

6. *Matrix Sign Function*:

The standard method for computing the matrix sign function is the Newton iteration

$$X_{k+1} = \frac{1}{2}(X_k + X_k^{-1}), \quad X_0 = A,$$

which converges quadratically to sign(A), provided A has no pure imaginary eigenvalues. In practice, a scaled iteration

$$X_{k+1} = \frac{1}{2}(\mu_k X_k + \mu_k^{-1} X_k^{-1}), \quad X_0 = A$$

is used, where the scale parameters μ_k are chosen to reduce the number of iterations needed to enter the regime where asymptotic quadratic convergence sets in [Bye87], [Hig08, Chap. 5], [KL92].

The Newton–Schulz iteration

$$X_{k+1} = \frac{1}{2} X_k (3I - X_k^2), \quad X_0 = A,$$

involves no matrix inverses, but convergence is guaranteed only for $\|I - A^2\| < 1$.

A Padé family of iterations

$$X_{k+1} = X_k p_{\ell m}\left(1 - X_k^2\right) q_{\ell m}\left(1 - X_k^2\right)^{-1}, \quad X_0 = A$$

is obtained in [KL91], where $p_{\ell m}(\xi)/q_{\ell m}(\xi)$ is the $[\ell/m]$ Padé approximant to $(1-\xi)^{-1/2}$. The iteration is globally convergent to $\operatorname{sign}(A)$ for $\ell = m-1$ and $\ell = m$, and for $\ell \geq m-1$ is convergent when $\|I - A^2\| < 1$, with order of convergence $\ell + m + 1$ in all cases.

A *matrix polynomial* is a polynomial with matrix coefficients. The simplest example comes from the standard linear algebraic eigenvalue problem $A\mathbf{x} = \lambda\mathbf{x}$ for a square matrix A. Introducing $P(\lambda) = I\lambda^1 - A\lambda^0$, which is a matrix polynomial of degree one with the coefficients I and $-A$, the standard eigenvalue problem can be written in the equivalent form

$$P(\lambda)\mathbf{x} = 0.$$

The *generalized eigenvalue problem* $A\mathbf{x} = \lambda B\mathbf{x}$ (cf. Chapter 56 in this book) can be written in an analogous way with $P(\lambda) = B\lambda^1 - A\lambda^0$. In order to remind the reader of the strong connection between matrix polynomials and eigenvalue problems, and in agreement with the majority of the literature on matrix polynomials, the symbol λ (rather than x) is used throughout this chapter to denote the indeterminant of polynomials.

In general, the equation $P(\lambda)\mathbf{x} = 0$ with a matrix polynomial $P(\lambda)$ is called a *polynomial eigenvalue problem*. Clearly, such problems are a special case of nonlinear eigenvalue problems and, consequently, some results and algorithms stated in Chapter 60 of this book are applicable to matrix polynomials as well. However, the special polynomial structure and the wealth of practical applications make the study of matrix polynomials an important subject in its own right. Major application areas include differential and difference equations as they appear, e.g., in control theory and structural mechanics. In addition, the theory of matrix polynomials contains standard and generalized eigenvalue problems as special cases.

Israel Gohberg, Peter Lancaster, and Leiba Rodman initiated the active and yet ongoing development in the field of matrix polynomials with their fundamental contributions in the mid to late 1970s. They have significantly influenced the field over more than three decades. Their book *Matrix Polynomials*, published by Academic Press in 1982 and republished by SIAM in the Classics in Applied Mathematics series in 2009, remains the only systematic study of the theory of matrix polynomials to this date. It has been a major source in the preparation of this chapter.

18.1 Basic Definitions and Facts

In this section, F denotes an arbitrary field.

Definitions:

A **matrix polynomial** $P(\lambda)$ of size $m \times n$ over the field F is a polynomial in the variable λ with coefficients that are $m \times n$ matrices over F, i.e.,

$$P(\lambda) = \sum_{j=0}^{\ell} A_j \lambda^j, \quad \text{where} \quad A_0, A_1, \dots, A_\ell \in F^{m\times n}. \tag{18.1}$$

For notational convenience one usually writes λ instead of λ^1 and skips the term λ^0.

The number ℓ in Eq. (18.1) is called the **grade** or the **extended degree** of $P(\lambda)$. The matrix A_ℓ is called the **leading coefficient** of $P(\lambda)$. (Note that $A_\ell = 0$ is allowed.)

A matrix polynomial that has grade 1, i.e., that is of the form $A_1\lambda + A_0$, is called a **matrix pencil**.

If at least one matrix A_j in Eq. (18.1) is nonzero, then the largest integer $k \leq \ell$ for which $A_k \neq 0$ is called the **degree** of $P(\lambda)$, which is denoted by $\deg(P(\lambda)) = k$. If all matrices A_j are zero, then by convention $\deg(P(\lambda)) := -\infty$.

The matrix polynomial $P(\lambda)$ in Eq. (18.1) can be associated in the canonical way with an $m \times n$ **polynomial matrix** (also widely known as **lambda matrix**), i.e., an $m \times n$ matrix with entries from $F[\lambda]$, the ring of polynomials over F. Then **scalar multiplication**, **addition**, and **multiplication** of matrix polynomials are the same operations as for general matrices with entries in a commutative ring.

If $n = m$, then $P(\lambda)$ is called a **square** matrix polynomial and n is called the **order** of $P(\lambda)$. If additionally the leading coefficient is equal to the identity matrix I, then $P(\lambda)$ is called **monic**.

A matrix polynomial $P(\lambda)$ is called **regular** if it is square and if $\det P(\lambda) \in F[\lambda]$ is not the zero polynomial. Otherwise $P(\lambda)$ is called **singular**.

Let $P_1(\lambda)$ and $P_2(\lambda)$ be square matrix polynomials of the same order, and let the leading coefficient of $P_2(\lambda)$ be nonsingular (i.e., have a nonzero determinant). The matrix polynomials $Q(\lambda)$ and $R(\lambda)$ are respectively called the **right quotient** and **right remainder** of $P_1(\lambda)$ upon division by $P_2(\lambda)$, if $P_1(\lambda) = Q(\lambda)P_2(\lambda) + R(\lambda)$ and $\deg(R(\lambda)) < \deg(P_2(\lambda))$. If $R(\lambda) = 0$, then $P_1(\lambda)$ is called **right divisible** by $P_2(\lambda)$. The matrix polynomials $\widehat{Q}(\lambda)$ and $\widehat{R}(\lambda)$ are respectively called the **left quotient** and **left remainder** of $P_1(\lambda)$ upon division by $P_2(\lambda)$, if $P_1(\lambda) = P_2(\lambda)\widehat{Q}(\lambda) + \widehat{R}(\lambda)$ and $\deg(\widehat{R}(\lambda)) < \deg(P_2(\lambda))$. If $\widehat{R}(\lambda) = 0$, then $P_1(\lambda)$ is called **left divisible** by $P_2(\lambda)$.

Facts:

The following results can be found in [Gan59, Chap. IV].

1. If $P_1(\lambda)$ and $P_2(\lambda)$ are square matrix polynomials of the same order, then the degree of their product satisfies

$$\deg(P_1(\lambda)P_2(\lambda)) \leq \deg(P_1(\lambda)) + \deg(P_2(\lambda)),$$

   with equality if both $P_1(\lambda)$ and $P_2(\lambda)$ have nonzero leading coefficients and at least one of them is nonsingular.
2. Let $P_1(\lambda)$ and $P_2(\lambda)$ be square matrix polynomials of the same order and let the leading coefficient of $P_2(\lambda)$ be nonsingular. Then there exists a right quotient $Q(\lambda)$ and a right remainder $R(\lambda)$ of $P_1(\lambda)$ upon division by $P_2(\lambda)$, and the nonzero coefficients of both $Q(\lambda)$ and $R(\lambda)$ are uniquely determined. An analogous result holds for left division.
3. Let $P(\lambda)$ be of the form (18.1) with $n = m$. Then for every matrix $A \in F^{n\times n}$, the right and the left remainder of $P(\lambda)$ upon division by the matrix pencil $I\lambda - A$ are

respectively given by the matrices

$$\sum_{j=0}^{\ell} A_j A^j = P(A) \quad \text{and} \quad \sum_{j=0}^{\ell} A^j A_j.$$

In particular, $P(\lambda)$ is right divisible by $I\lambda - A$ if and only if $P(A) = 0$.

Examples:

1. The matrix polynomials

$$P_1(\lambda) = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \lambda + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad P_2(\lambda) = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \lambda^2 + \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \lambda + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

are both of degree 1, of order 2, and regular, since $\det P_1(\lambda) = \det P_2(\lambda) \equiv 1$. While $P_1(\lambda)$ has grade 1 and is a matrix pencil, $P_2(\lambda)$ has grade 2 and thus is not a matrix pencil. Both matrix polynomials can be canonically identified with the polynomial matrix

$$\begin{bmatrix} 1 & \lambda \\ 0 & 1 \end{bmatrix} \in F[\lambda]^{2\times 2}.$$

In the remainder of this chapter, there will be no distinction between matrix polynomials and matrices with polynomial entries, unless it is important to specify the grade of the matrix polynomial.

2. The matrix polynomial

$$P(\lambda) = \begin{bmatrix} 1 & 0 \\ 0 & -1 \\ 1 & 0 \end{bmatrix} \lambda^3 + \begin{bmatrix} 0 & -1 \\ 1 & 1 \\ -1 & 0 \end{bmatrix} \lambda = \begin{bmatrix} \lambda^3 & -\lambda \\ \lambda & -\lambda^3 + \lambda \\ \lambda^3 - \lambda & 0 \end{bmatrix}$$

is of degree 3, of size 3×2, and singular since it is not square.

3. The matrix polynomial

$$P(\lambda) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} \lambda^2 + \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix} \lambda + \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} \lambda^2 & 0 & \lambda \\ 0 & \lambda^2 + \lambda & 0 \\ \lambda & 0 & 1 \end{bmatrix}$$

is of degree 2, of order 3, and singular since $\det P(\lambda) \equiv 0$.

4. The matrix polynomial $P_1(\lambda) = \begin{bmatrix} 0 & \lambda^2 \\ -\lambda^2 & \lambda^2 \end{bmatrix}$ is right and left divisible by $P_2(\lambda) = \begin{bmatrix} \lambda & \lambda \\ 0 & \lambda \end{bmatrix}$, since

$$P_1(\lambda) = \begin{bmatrix} 0 & \lambda \\ -\lambda & 2\lambda \end{bmatrix} P_2(\lambda) \quad \text{and} \quad P_1(\lambda) = P_2(\lambda) \begin{bmatrix} \lambda & 0 \\ -\lambda & \lambda \end{bmatrix}.$$

5. Unlike for scalar polynomials, right (or left) quotients and remainders do not always exist for matrix polynomials. A simple example is given by a regular matrix polynomial $P_1(\lambda) = A_0$ and a singular matrix polynomial $P_2(\lambda) = B_0 \neq 0$ (both of the same order n). In this case there exist no matrix polynomials $Q(\lambda)$ and $R(\lambda)$ with $\deg(R(\lambda)) < \deg(P_2(\lambda))$ such that $P_1(\lambda) = Q(\lambda)P_2(\lambda) + R(\lambda)$ or $P_1(\lambda) = P_2(\lambda)Q(\lambda) + R(\lambda)$.

18.2 Equivalence and the Smith Form

This section deals with the equivalence and the Smith form of $m \times n$ matrix polynomials over an arbitrary field F. The Smith form, which is named after the work of Henry John Stephen

Smith [Smi61], is considered for square matrix polynomials also in Section 6.6. Several concepts in the following definitions and facts (in particular unimodularity, equivalence, and the Smith form) are studied also in Chapter 32 in the context of matrices over integral domains.

Definitions:

A square matrix polynomial $P(\lambda)$ is called **unimodular**, if $\det P(\lambda)$ is a nonzero constant independent of λ.

Two matrix polynomials $P_1(\lambda)$ and $P_2(\lambda)$ of the same size $m \times n$ are called **equivalent** if there exist unimodular matrix polynomials $E(\lambda)$ of order m and $F(\lambda)$ of order n such that

$$P_1(\lambda) = E(\lambda)P_2(\lambda)F(\lambda).$$

Two matrix pencils $L_1(\lambda) = A_1\lambda + A_0$ and $L_2(\lambda) = B_1\lambda + B_0$ of the same size $m \times n$ are called **strictly equivalent** if there exist nonsingular matrices $Y \in F^{m\times m}$ and $Z \in F^{n\times n}$ such that $YL_1(\lambda)Z = L_2(\lambda)$, i.e., if $YA_1Z = B_1$ and $YA_0Z = B_0$.

The **Smith form** (or **Smith normal form**) of an $m \times n$ matrix polynomial $P(\lambda)$ is an $m \times n$ polynomial matrix $D(\lambda)$ equivalent to $P(\lambda)$ which has the form

$$D(\lambda) = \begin{bmatrix} D_1(\lambda) & 0 \\ 0 & 0 \end{bmatrix}, \quad D_1(\lambda) = \operatorname{diag}\bigl(d_1(\lambda), d_2(\lambda), \dots, d_r(\lambda)\bigr), \tag{18.2}$$

where $d_1(\lambda), \dots, d_r(\lambda)$ are monic scalar polynomials, such that $d_i(\lambda)$ is a divisor of $d_{i+1}(\lambda)$ for $i = 1, \dots, r-1$. The polynomials $d_1(\lambda), \dots, d_r(\lambda)$ are called the **invariant polynomials** of $P(\lambda)$.

Let the invariant polynomial $d_r(\lambda)$ of $P(\lambda)$ with the largest index r be factorized as

$$d_r(\lambda) = \varphi_1(\lambda)^{\alpha_{r1}}\varphi_2(\lambda)^{\alpha_{r2}} \cdots \varphi_s(\lambda)^{\alpha_{rs}},$$

where $\alpha_{r1}, \alpha_{r2}, \dots, \alpha_{rs}$ are positive integers and $\varphi_1(\lambda), \varphi_2(\lambda), \dots, \varphi_s(\lambda)$ are distinct monic polynomials that are irreducible over F. Then, since $d_i(\lambda)$ is a divisor of $d_{i+1}(\lambda)$ for $i = 1, \dots, r-1$,

$$d_i(\lambda) = \varphi_1(\lambda)^{\alpha_{i1}}\varphi_2(\lambda)^{\alpha_{i2}} \cdots \varphi_s(\lambda)^{\alpha_{is}}, \quad i = 1, \dots, r-1,$$

where $\alpha_{rj} \geq \cdots \geq \alpha_{2j} \geq \alpha_{1j} \geq 0$ for $j = 1, \dots, s$. Then the nonconstant factors $\varphi_j(\lambda)^{\alpha_{ij}}$, for $j = 1, \dots, s$ and $i = 1, \dots, r$, in these factorizations are called the **elementary divisors** of $P(\lambda)$ (in the field F).

The **reversal** (or **dual**) **polynomial** of a matrix polynomial $P(\lambda)$ with grade ℓ is the matrix polynomial

$$\operatorname{rev} P(\lambda) := \lambda^{\ell} P\left(\frac{1}{\lambda}\right) := \sum_{j=0}^{\ell} A_{\ell-j}\lambda^{j}.$$

The elementary divisors of $\operatorname{rev} P(\lambda)$ of the form λ^{α} for some positive integer α are called the **infinite elementary divisors** of $P(\lambda)$.

Facts:

The following results can be found in [Gan59, Chaps. VI, VII and XII], [GLR82, Chap. S1], or [Lan02, Chap. 3].

1. The above concept of equivalence defines an equivalence relation on $F[\lambda]^{m\times n}$.
2. Two square matrix pencils $A_1\lambda + A_0$ and $B_1\lambda + B_0$ with nonsingular leading coefficients A_1 and B_1 are strictly equivalent if and only if they are equivalent.

3. For every $m \times n$ matrix polynomial $P(\lambda)$ there exist unimodular matrix polynomials $E(\lambda)$ of order m and $F(\lambda)$ of order n, such that $E(\lambda)P(\lambda)F(\lambda) = D(\lambda)$, where $D(\lambda)$ is the Smith form of $P(\lambda)$ as in Eq. (18.2). The integer r and the polynomials $d_1(\lambda), \ldots, d_r(\lambda)$ are uniquely determined.
4. Let $P(\lambda)$ be an $m \times n$ matrix polynomial. Let $p_k(\lambda)$ be the greatest common divisor (monic) of the minors of $P(\lambda)$ of order k, if not all of them are zero, and let $p_k(\lambda) \equiv 0$ if all minors of order k of $P(\lambda)$ are zero. Furthermore, let $p_0(\lambda) \equiv 1$, and let $D(\lambda)$ be the Smith form of $P(\lambda)$ as in Eq. (18.2). Then r is the maximal integer such that $p_r(\lambda) \not\equiv 0$, and
$$d_i(\lambda) = \frac{p_i(\lambda)}{p_{i-1}(\lambda)}, \quad i = 1, \ldots, r.$$
5. The Smith form $D(\lambda)$ of a matrix polynomial $P(\lambda)$ can be obtained by systematically performing a sequence of the following elementary row and column operations on $P(\lambda)$:
   (a) Multiplication of any row (or column) by a nonzero element $\alpha \in F$.
   (b) Addition to any row (or column) of any other row (or column) multiplied by an arbitrary polynomial from $F[\lambda]$.
   (c) Interchange of any two rows (or columns).
6. If $P(\lambda)$ is a square matrix polynomial, then $\det P(\lambda)$ is equal to the product of the invariant polynomials of $P(\lambda)$.
7. The sum of the degrees of the elementary divisors of a regular matrix polynomial $P(\lambda)$ is equal to the degree of $\det P(\lambda)$.
8. A matrix polynomial $P(\lambda) \in F[\lambda]^{n\times n}$ is unimodular if and only if $P(\lambda)$ is a finite product of elementary matrices representing the three elementary row and column operations described in Fact 5.
9. Let $P(\lambda)$ be an $n \times n$ matrix polynomial of the form (18.1) over $\mathbb{C}$.
   If $P(\lambda)$ is regular, then the degree of $\det P(\lambda)$ is equal to the dimension of the solution space of the homogeneous ordinary differential equation system
$$P\left(\frac{d}{dt}\right)x = 0, \quad \text{where} \quad P\left(\frac{d}{dt}\right)x := \sum_{j=0}^{\ell} A_j \frac{d^j x}{dt^j}, \tag{18.3}$$
   and $x = x(t) : \mathbb{R} \to \mathbb{C}^n$ is an ℓ-times differentiable function.
   The system
$$P\left(\frac{d}{dt}\right)x = f$$
   has a solution for every-right hand side $f = f(t)$ (which is sufficiently often differentiable) if and only if $P(\lambda)$ is regular.
10. If $P(\lambda)$ is a regular matrix polynomial of the form (18.1) over $\mathbb{C}$, then the degree of $\det P(\lambda)$ is equal to the dimension of the solution space of the homogeneous difference equation
$$\sum_{j=0}^{\ell} A_j \mathbf{x}_{j+k} = 0, \quad k = 0, 1, 2, \ldots .$$
11. If $P_1(\lambda)$ and $P_2(\lambda)$ are two arbitrary matrix polynomials, then the list of elementary divisors of the block-diagonal matrix polynomial $\text{diag}(P_1(\lambda), P_2(\lambda))$ is obtained by concatenating the lists the elementary divisors of $P_1(\lambda)$ and $P_2(\lambda)$.
12. Two regular matrix pencils of the same size are strictly equivalent if and only if they have the same finite and infinite elementary divisors.

13. Two matrix polynomials of the same size are equivalent if and only if they have the same Smith form.
14. The matrix pencils $I_n\lambda - A$ and $I_n\lambda - B$ are equivalent if and only if the matrices $A, B \in F^{n\times n}$ are similar.
15. The Smith form, invariant polynomials, and elementary divisors of the matrix pencil $I\lambda - A$ are the same as the corresponding items for the matrix $A \in F^{n\times n}$.
16. The characteristic polynomial of a matrix $A \in F^{n\times n}$ is equal to the product of the invariant polynomials of the matrix pencil $I_n\lambda - A$.
17. The minimal polynomial of a matrix $A \in F^{n\times n}$ is equal to the highest invariant polynomial $d_n(\lambda)$ of the matrix pencil $I_n\lambda - A$.

Examples:

1. The matrix polynomial $P(\lambda) = \begin{bmatrix} \lambda^2+1 & \lambda^2 \\ \lambda^2 & \lambda^2-1 \end{bmatrix}$ is unimodular, since $\det P(\lambda) \equiv -1$.
2. The matrix polynomial

$$P(\lambda) = I_6\lambda - A, \quad A = \operatorname{diag}\left(\begin{bmatrix} 2 \end{bmatrix}, \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix}, \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix}, \begin{bmatrix} 3 \end{bmatrix} \right) \in \mathbb{Q}^{6\times 6}$$

has the Smith form

$$D(\lambda) = \operatorname{diag}(d_1(\lambda), \ldots, d_6(\lambda)) = \operatorname{diag}\Big(1,\ 1,\ 1,\ \lambda-2,\ (\lambda-2)^2,\ (\lambda-2)^2(\lambda-3)\Big),$$

and the elementary divisors of $P(\lambda)$ are $\lambda-2$, $(\lambda-2)^2$, $(\lambda-2)^2$, and $\lambda-3$. The characteristic polynomial of A is the product $d_4(\lambda)d_5(\lambda)d_6(\lambda)$, which is equal to $\det P(\lambda)$, and the minimal polynomial of A is $d_6(\lambda)$.
3. If the matrix polynomial $P(\lambda) \in F[\lambda]^{n\times n}$ is unimodular, then by Fact 8 it is a finite product of elementary matrices which are all unimodular. Thus, $P(\lambda)$ is invertible in $F[\lambda]^{n\times n}$ with $P(\lambda)^{-1} = (\det P(\lambda))^{-1} \operatorname{adj} P(\lambda)$, which is itself a unimodular matrix polynomial. Consequently, the Smith form of $P(\lambda)$ is the identity matrix I.
4. The matrix polynomial

$$P(\lambda) = \begin{bmatrix} \lambda^4(\lambda-1)+\lambda & \lambda^2(\lambda-1) \\ \lambda^3(\lambda-1) & \lambda(\lambda-1) \end{bmatrix}$$

has the Smith form $D(\lambda) = \operatorname{diag}\big(\lambda,\ \lambda(\lambda-1)\big)$. The elementary divisors of $P(\lambda)$ are λ, λ, and $\lambda - 1$, and $\det P(\lambda) = \lambda^2(\lambda-1)$.
This matrix polynomial can be written as

$$P(\lambda) = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}\lambda^5 + \begin{bmatrix} -1 & 0 \\ 1 & 0 \end{bmatrix}\lambda^4 + \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}\lambda^3 + \begin{bmatrix} 0 & -1 \\ 0 & 1 \end{bmatrix}\lambda^2 + \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}\lambda,$$

which is a matrix polynomial of grade 5 with corresponding reversal given by

$$\begin{aligned} \operatorname{rev} P(\lambda) &= \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}\lambda^4 + \begin{bmatrix} 0 & -1 \\ 0 & 1 \end{bmatrix}\lambda^3 + \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}\lambda^2 + \begin{bmatrix} -1 & 0 \\ 1 & 0 \end{bmatrix}\lambda + \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} = \\ &= \begin{bmatrix} \lambda^4-\lambda+1 & -\lambda^3+\lambda^2 \\ -\lambda^2+\lambda & -\lambda^4+\lambda^3 \end{bmatrix}. \end{aligned}$$

The Smith form of $\operatorname{rev} P(\lambda)$ is $\operatorname{diag}(1,\ \lambda^7(\lambda-1))$, and thus $P(\lambda)$ has one infinite elementary divisor of degree 7.

5. The matrix polynomials

$$P_1(\lambda) = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \lambda^2 + \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \lambda + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad P_2(\lambda) = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \lambda + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix},$$

have grades 2 and 1, respectively, but they both correspond to the same polynomial matrix in $F[\lambda]^{2\times 2}$. Their reversal polynomials are given by

$$\operatorname{rev} P_1(\lambda) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \lambda^2 + \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \lambda + \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \quad \text{and} \quad \operatorname{rev} P_2(\lambda) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \lambda + \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix},$$

and the Smith forms of $\operatorname{rev} P_1(\lambda)$ and $\operatorname{rev} P_2(\lambda)$ are

$$D_1(\lambda) = \begin{bmatrix} \lambda & 0 \\ 0 & \lambda^3 \end{bmatrix} \quad \text{and} \quad D_2(\lambda) = \begin{bmatrix} 1 & 0 \\ 0 & \lambda^2 \end{bmatrix},$$

respectively. Thus, $P_1(\lambda)$ has two infinite elementary divisors, of degrees 1 and 3, while $P_2(\lambda)$ has one infinite elementary divisor, of degree 2. This example shows that the number and degrees of infinite elementary divisors can only be determined if the grade of $P(\lambda)$ is specified.

18.3 Spectral Theory of Matrix Polynomials

Throughout this section $P(\lambda) = \sum_{j=0}^{\ell} A_j \lambda^j$ is a regular matrix polynomial of order n over the field $F = \mathbb{C}$.

Definitions:

The complex number λ_0 is called a **(finite) eigenvalue** of $P(\lambda)$, if $\det P(\lambda_0) = 0$. The multiplicity of λ_0 as a root of the complex polynomial $\det P(\lambda)$ is called the **algebraic multiplicity** of the eigenvalue λ_0.

Let λ_0 be an eigenvalue of $P(\lambda)$, and let $(\lambda - \lambda_0)^{\alpha_1}, \ldots, (\lambda - \lambda_0)^{\alpha_s}$ be the elementary divisors of $P(\lambda)$ that contain the irreducible polynomial $\lambda - \lambda_0$. Then the number s of elementary divisors is called the **geometric multiplicity** of the eigenvalue λ_0, and the positive numbers $\alpha_1, \ldots, \alpha_s$ are called the **partial multiplicities** of the eigenvalue λ_0.

If the grade of $P(\lambda)$ is specified and hence $\operatorname{rev} P(\lambda)$ is well defined, then $P(\lambda)$ has the **eigenvalue infinity** (∞) whenever 0 is an eigenvalue of $\operatorname{rev} P(\lambda)$. The **algebraic multiplicity** and the **partial multiplicities** of the eigenvalue ∞ of $P(\lambda)$ are defined to be the same as the corresponding multiplicities of the eigenvalue 0 of $\operatorname{rev} P(\lambda)$.

A sequence of vectors $\mathbf{x}_0, \mathbf{x}_1, \ldots, \mathbf{x}_{k-1} \in \mathbb{C}^n$ is called a **Jordan chain of length** k of $P(\lambda)$ corresponding to the eigenvalue λ_0, if $\mathbf{x}_0 \neq 0$ and

$$\sum_{i=0}^{j} \frac{1}{i!} P^{(i)}(\lambda_0) \mathbf{x}_{j-i} = 0, \quad j = 0, 1, \ldots, k-1,$$

where $P^{(i)}(\lambda_0)$ denotes the i-th derivative of the matrix polynomial $P(\lambda)$ as a function of the complex variable λ evaluated at λ_0. The nonzero vector $\mathbf{x}_0$ is called an **eigenvector** of $P(\lambda)$ corresponding to the eigenvalue λ_0, and the subsequent vectors $\mathbf{x}_1, \ldots, \mathbf{x}_{k-1}$ (not necessarily being all nonzero) are called **generalized eigenvectors** corresponding to λ_0.

A matrix polynomial $v(\lambda)$ of size $n \times 1$ is called a **root polynomial** of $P(\lambda)$ corresponding to the eigenvalue λ_0 if $v(\lambda_0) \neq 0$ and $P(\lambda_0)v(\lambda_0) = 0$. The multiplicity of λ_0 as a zero of $P(\lambda)v(\lambda)$ is called the **order** of the root polynomial $v(\lambda)$.

Let $P(\lambda)$ be regular, let $\lambda_0 \in \mathbb{C}$ be an eigenvalue of $P(\lambda)$, and let $r := \dim \ker P(\lambda_0)$. Inductively, define r root polynomials $v_1(\lambda), \ldots, v_r(\lambda)$ as follows:

$$v_i(\lambda) = \sum_{j=0}^{k_i-1} \mathbf{v}_j^{(i)} (\lambda - \lambda_0)^j$$

is a root polynomial of maximal order k_1 if $i = 1$, and if $i > 1$ then it is a root polynomial with maximal order k_i among all root polynomials whose coefficient corresponding to $(\lambda - \lambda_0)^0$ is not in the span of $\mathbf{v}_0^{(1)}, \ldots, \mathbf{v}_0^{(i-1)}$. Then the list of vectors

$$\mathbf{v}_0^{(1)}, \ldots, \mathbf{v}_{k_1-1}^{(1)}; \quad \mathbf{v}_0^{(2)}, \ldots, \mathbf{v}_{k_2-1}^{(2)}; \quad \ldots; \quad \mathbf{v}_0^{(r)}, \ldots, \mathbf{v}_{k_r-1}^{(r)}; \tag{18.4}$$

is called a **canonical set of Jordan chains** of $P(\lambda)$ corresponding to λ_0. Let

$$J(\lambda_0) := \operatorname{diag}(J_{k_1}(\lambda_0), \ldots, J_{k_r}(\lambda_0)) \quad \text{and} \quad X(\lambda_0) := \begin{bmatrix} \mathbf{v}_0^{(1)} \ldots \mathbf{v}_{k_r-1}^{(r)} \end{bmatrix},$$

where $J_{k_j}(\lambda_0)$ denotes the Jordan block of size k_j corresponding to the eigenvalue λ_0, and where the list of columns of $X(\lambda_0)$ coincides with the list of vectors in Eq. (18.4). Then $(X(\lambda_0), J(\lambda_0))$ is called a **Jordan pair** of $P(\lambda)$ corresponding to λ_0.

Let $P(\lambda)$ be regular with pairwise distinct eigenvalues $\lambda_1, \ldots, \lambda_q \in \mathbb{C}$, and let $(X(\lambda_i), J(\lambda_i))$ be Jordan pairs of $P(\lambda)$ corresponding to λ_i for $i = 1, \ldots, q$. Then (X_F, J_F) with

$$X_F := \begin{bmatrix} X(\lambda_1) \; X(\lambda_2) \ldots X(\lambda_q) \end{bmatrix}, \quad J_F := \operatorname{diag}(J(\lambda_1), J(\lambda_2), \ldots, J(\lambda_q))$$

is called a **finite Jordan pair** of $P(\lambda)$. If ∞ is an eigenvalue of $P(\lambda)$, then a Jordan pair (X_∞, J_∞) of $\operatorname{rev} P(\lambda)$ corresponding to the eigenvalue 0 is called an **infinite Jordan pair** of $P(\lambda)$.

Let $P(\lambda)$ be regular. A pair of matrices $(X, T) \in \mathbb{C}^{n \times n\ell} \times \mathbb{C}^{n\ell \times n\ell}$ is called a **decomposable pair** of $P(\lambda)$, if the following conditions are satisfied:

1. $X = \begin{bmatrix} X_1 & X_2 \end{bmatrix}$ and $T = \operatorname{diag}(T_1, T_2)$, where $X_1 \in \mathbb{C}^{n \times m}$ and $T_1 \in \mathbb{C}^{m \times m}$ for some m, $0 \le m \le n\ell$;
2. the matrix $\begin{bmatrix} X_1 & X_2 T_2^{\ell-1} \\ X_1 T_1 & X_2 T_2^{\ell-2} \\ \vdots & \vdots \\ X_1 T_1^{\ell-1} & X_2 \end{bmatrix} \in \mathbb{C}^{n\ell \times n\ell}$ is nonsingular;
3. $\sum\limits_{j=0}^{\ell} A_j X_1 T_1^j = 0$ and $\sum\limits_{j=0}^{\ell} A_j X_2 T_2^{\ell-j} = 0$.

The integer m is called the **parameter** of the decomposable pair (X, T). Two decomposable pairs (X_1, T_1) and (X_2, T_2) with the same parameter m are called **similar** if there exist nonsingular matrices $Q_1 \in \mathbb{C}^{m \times m}$ and $Q_2 \in \mathbb{C}^{(n\ell-m)\times(n\ell-m)}$ such that $Q := \operatorname{diag}(Q_1, Q_2)$ satisfies $X_2 = X_1 Q$ and $T_2 = Q^{-1} T_1 Q$.

Let $P(\lambda)$ be monic. A pair of matrices $(X, T) \in \mathbb{C}^{n \times n\ell} \times \mathbb{C}^{n\ell \times n\ell}$ is called a **standard pair** of $P(\lambda)$, if

$$\text{the matrix} \begin{bmatrix} X \\ XT \\ \vdots \\ XT^{\ell-1} \end{bmatrix} \in \mathbb{C}^{n\ell \times n\ell} \text{ is nonsingular and } \sum_{j=0}^{\ell} A_j X T^j = 0.$$

Two standard pairs (X_1, T_1) and (X_2, T_2) of $P(\lambda)$ are called **similar** if there exists a nonsingular matrix $S \in \mathbb{C}^{n\ell \times n\ell}$ such that $X_2 = X_1 S$ and $T_2 = S^{-1} T_1 S$.

Facts:

The following results can be found in [GLR82, Chaps. 1, 7, and S.1]. Note that many results in [GLR82, Chap. 1] are formulated for monic matrix polynomials only. But as the authors say on page 28, the monicity is not essential and not used in the proofs, so that the results actually hold for general regular matrix polynomials.

1. The eigenvalues of the matrix pencil $I\lambda - A$ and their algebraic multiplicities, geometric multiplicities, and Jordan chains are the same as the corresponding items for the matrix $A \in \mathbb{C}^{n\times n}$.
2. The vectors $\mathbf{x}_0, \ldots, \mathbf{x}_{k-1}$ form a Jordan chain of length k of $P(\lambda)$ corresponding to the eigenvalue λ_0 if and only if $\mathbf{x}_0 \neq 0$ and
$$\sum_{j=0}^{\ell} A_j X_0 J_k(\lambda_0)^j = 0, \quad \text{where} \quad X_0 := \left[\mathbf{x}_0 \ldots \mathbf{x}_{k-1}\right] \in \mathbb{C}^{n\times k}.$$
3. The order of any root polynomial of $P(\lambda)$ corresponding to the eigenvalue λ_0 does not exceed the algebraic multiplicity of λ_0.
4. If $v(\lambda) = \sum_{j=0}^{s} \mathbf{v}_j(\lambda - \lambda_0)^j$ with $\mathbf{v}_0, \ldots, \mathbf{v}_s \in \mathbb{C}^n$ and $\mathbf{v}_0 \neq 0$ is a root polynomial of $P(\lambda)$ of order k corresponding to the eigenvalue λ_0, then $\mathbf{v}_0, \ldots, \mathbf{v}_{k-1}$ is a Jordan chain of length k of $P(\lambda)$ corresponding to λ_0.
5. If $\mathbf{v}_0, \ldots, \mathbf{v}_{k-1}$ is a Jordan chain of length k of $P(\lambda)$ corresponding to the eigenvalue λ_0, then
$$v(\lambda) = \sum_{j=0}^{k-1} \mathbf{v}_j(\lambda - \lambda_0)^j + (\lambda - \lambda_0)^k w(\lambda)$$
is a root polynomial of $P(\lambda)$ of order k corresponding to λ_0, where $w(\lambda)$ is an arbitrary matrix polynomial of size $n \times 1$.
6. Let $\lambda_0 \in \mathbb{C}$ and let $E(\lambda)$ and $F(\lambda)$ be two matrix polynomials of order n with $\det E(\lambda_0) \neq 0$ and $\det F(\lambda_0) \neq 0$. Then the following two statements are equivalent for the k vectors $\mathbf{v}_0, \ldots, \mathbf{v}_{k-1}$:
   (a) $\mathbf{v}_0, \ldots, \mathbf{v}_{k-1}$ form a Jordan chain of length k of $E(\lambda)P(\lambda)F(\lambda)$ corresponding to the eigenvalue λ_0.
   (b) The vectors
   $$\mathbf{w}_j = \sum_{i=0}^{j} \frac{1}{i!} F^{(i)}(\lambda_0)\mathbf{v}_{j-i}, \quad j = 0, 1, \ldots, k-1,$$
   form a Jordan chain of length k of $P(\lambda)$ corresponding to the eigenvalue λ_0.

   In particular, $P(\lambda)$ and $E(\lambda)P(\lambda)$ have the same set of Jordan chains corresponding to λ_0.
7. The lengths $k_1, \ldots, k_r$ of the Jordan chains in a canonical set of Jordan chains of $P(\lambda)$ corresponding to the eigenvalue λ_0 are equal to the degrees of the elementary divisors of the form $(\lambda - \lambda_0)^\alpha$ in the Smith form of $P(\lambda)$, i.e., they are equal to the partial multiplicites of λ_0.
8. The sum $\sum_{i=1}^{r} k_i$ of the lengths $k_1, \ldots, k_r$ of the Jordan chains in a canonical set of Jordan chains of $P(\lambda)$ corresponding to the eigenvalue λ_0 is equal to the algebraic multiplicity of λ_0.
9. A pair $(\widehat{X}, \widehat{J}) \in \mathbb{C}^{n\times\mu} \times \mathbb{C}^{\mu\times\mu}$ with $\widehat{J}$ in Jordan canonical form having the only eigenvalue $\lambda_0 \in \mathbb{C}$, is a Jordan pair of $P(\lambda)$ corresponding to λ_0 if and only if the following conditions are satisfied:
   (a) $\det P(\lambda)$ has λ_0 as a zero with multiplicity μ;

(b) $\operatorname{rank}\begin{bmatrix} \widehat{X} \\ \widehat{X}\widehat{J} \\ \vdots \\ \widehat{X}\widehat{J}^{\ell-1} \end{bmatrix} = \mu$;

(c) $\sum\limits_{j=0}^{\ell} A_j \widehat{X}\widehat{J}^j = 0$.

10. Let $\lambda_0 \in \mathbb{C}$ be an eigenvalue of $P(\lambda)$ with algebraic multiplicity μ, and let $(X^{(1)}(\lambda_0), J^{(1)}(\lambda))$ and $(X^{(2)}(\lambda_0), J^{(2)}(\lambda))$ be two Jordan pairs of $P(\lambda)$ corresponding to λ_0. Then there exists a nonsingular matrix $S \in \mathbb{C}^{\mu\times\mu}$, such that
$$X^{(1)}(\lambda_0) = X^{(2)}(\lambda_0)S \quad \text{and} \quad J^{(1)}(\lambda_0) = S^{-1}J^{(2)}(\lambda_0)S.$$
11. Let $\lambda_0 = \infty$ be an eigenvalue of $P(\lambda)$ with algebraic multiplicity μ, and let $(X_\infty^{(1)}, J_\infty^{(1)})$ and $(X_\infty^{(2)}, J_\infty^{(2)})$ be two infinite Jordan pairs of $P(\lambda)$. Then there exists a nonsingular matrix $S \in \mathbb{C}^{\mu\times\mu}$, such that
$$X_\infty^{(1)} = X_\infty^{(2)}S \quad \text{and} \quad J_\infty^{(1)} = S^{-1}J_\infty^{(2)}S.$$
12. Let $(X_F^{(1)}, J_F^{(1)})$ and $(X_F^{(2)}, J_F^{(2)})$ be two finite Jordan pairs of $P(\lambda)$, and let $\nu = \deg(\det P(\lambda))$. Then there exists a nonsingular matrix $S \in \mathbb{C}^{\nu\times\nu}$, such that
$$X_F^{(1)} = X_F^{(2)}S \quad \text{and} \quad J_F^{(1)} = S^{-1}J_F^{(2)}S.$$
13. Let $A_\ell \neq 0$ and let the regular matrix polynomial $\widetilde{P}(\lambda)$ have the finite Jordan pair (X_F, J_F). Then $\widetilde{P}(\lambda)$ is a right divisor of $P(\lambda)$ if and only if
$$\sum_{j=0}^{\ell} A_j X_F J_F^j = 0.$$
14. The regular matrix polynomial $\widetilde{P}(\lambda)$ is a right divisor of $P(\lambda)$ if and only if each Jordan chain of $\widetilde{P}(\lambda)$ is a Jordan chain of $P(\lambda)$ corresponding to the same eigenvalue.

In the following results it is assumed that $P(\lambda)$ is monic, i.e., that $A_\ell = I_n$:

15. The vectors $\mathbf{x}_0, \ldots, \mathbf{x}_{k-1} \in \mathbb{C}^n$ form a Jordan chain of length k corresponding to the eigenvalue λ_0 of $P(\lambda)$ if and only if $\mathbf{x}_0 \neq 0$ and the function
$$x = x(t) := e^{\lambda_0 t}\sum_{j=0}^{k-1}\frac{t^j}{j!}\mathbf{x}_{k-1-j} \;:\; \mathbb{R} \to \mathbb{C}^n$$
is a solution of the homogeneous differential equation system (18.3).
16. A standard pair of $P(\lambda)$ is a decomposable pair of $P(\lambda)$ with parameter $m = n\ell$.
17. If $\det A_0 \neq 0$ and (X,T) is a standard pair of $P(\lambda)$, then T is nonsingular and (X, T^{-1}) is a decomposable pair of $P(\lambda)$ with parameter $m = 0$.
18. If (X_F, J_F) is a finite Jordan pair of $P(\lambda)$ and (X_∞, J_∞) is an infinite Jordan pair of $P(\lambda)$, then $([X_F\, X_\infty], \operatorname{diag}(J_F, J_\infty))$ is a decomposable pair of $P(\lambda)$.
19. Let (X,T) and $(\widetilde{X}, \widetilde{T})$ be two decomposable pairs of $P(\lambda)$ with the same parameter m and let $T = \operatorname{diag}(T_1, T_2)$ and $\widetilde{T} = \operatorname{diag}(\widetilde{T}_1, \widetilde{T}_2)$ with $T_1, \widetilde{T}_1 \in \mathbb{C}^{m\times m}$. If $\sigma(T_1) = \sigma(\widetilde{T}_1)$ and if there exists $\alpha \in \mathbb{C}$ such that
$$\sigma((T_1+\alpha I)^{-1}) \cup \sigma(T_2(I+\alpha T_2)^{-1}) = \sigma((\widetilde{T}_1+\alpha I)^{-1}) \cup \sigma(\widetilde{T}_2(I+\alpha\widetilde{T}_2)^{-1}) = \emptyset,$$
then (X,T) and $(\widetilde{X}, \widetilde{T})$ are similar. In particular, if $\sigma(T_1) = \sigma(\widetilde{T}_1)$ and $\sigma(T_2) = \sigma(\widetilde{T}_2) = \{0\}$, then (X,T) and $(\widetilde{X}, \widetilde{T})$ are similar.

20. Every Jordan pair of $P(\lambda)$ is a standard pair of $P(\lambda)$.
21. A standard pair of $P(\lambda)$ is given by (X_1, T_1) with

$$X_1 = \begin{bmatrix} I_n \ 0_{nn} \ \dots \ 0_{nn} \end{bmatrix} \quad \text{and} \quad T_1 = \begin{bmatrix} 0 & I_n & 0 & \dots & 0 \\ \vdots & 0 & I_n & \ddots & \vdots \\ \vdots & & \ddots & \ddots & 0 \\ 0 & \dots & \dots & 0 & I_n \\ -A_0 & -A_1 & -A_2 & \dots & -A_{\ell-1} \end{bmatrix}.$$

22. Any two standard pairs of $P(\lambda)$ are similar.

Examples:

1. [MMM11] Let $A \in \mathbb{C}^{n\times n}$ be invertible. Then the constant matrix polynomial $P(\lambda) = A$ with grade 0 has no (finite) eigenvalues, since $\det P(\lambda) = \det A \neq 0$ has no roots. Moreover, $\operatorname{rev} P(\lambda) = A$, so that $P(\lambda)$ does not have the eigenvalue ∞ either. On the other hand, for the matrix pencil $P(\lambda) = 0_n\lambda + A$, which has grade 1, the reversal polynomial $\operatorname{rev}P(\lambda) = \lambda A + 0_n$ has the eigenvalue 0 with algebraic multiplicity n. Thus, the pencil $P(\lambda) = 0_n\lambda + A$ has no finite eigenvalues but the eigenvalue ∞ with algebraic multiplicity n.
2. Consider the matrix polynomial $P(\lambda)$ from Example 18.2.3. Since $\det P(\lambda) = d_1(\lambda)d_2(\lambda) = \lambda^2(\lambda-1)$, the eigenvalues of $P(\lambda)$ are 0 with algebraic and geometric multiplicity 2, and 1 with algebraic and geometric multiplicity 1. The partial multiplicities of the zero eigenvalue are 1 and 1. Since $P(0) = 0$, each nonzero vector $\mathbf{x}_0 \in \mathbb{C}^2$ is an eigenvector of $P(\lambda)$ corresponding to the eigenvalue 0. A Jordan chain $\mathbf{x}_0, \mathbf{x}_1$ of length 2 would have to satisfy
$$\mathbf{x}_0 \neq 0 \quad \text{and} \quad \frac{1}{1!}P'(0)\mathbf{x}_0 + \frac{1}{0!}P(0)\mathbf{x}_1 = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \mathbf{x}_0,$$
which is impossible. Hence, there exists no Jordan chain of length 2.
3. The matrix polynomial
$$P(\lambda) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \lambda^2 + \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix} \lambda + \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} \lambda^2 & 0 & 0 \\ 1 & \lambda^2 & 0 \\ \lambda & 0 & \lambda^2 \end{bmatrix}$$
has $\det P(\lambda) = \lambda^6$, and thus $P(\lambda)$ has the eigenvalue $\lambda_0 = 0$ with algebraic multiplicity 6. Any Jordan chain of length 2 of $P(\lambda)$ corresponding to $\lambda_0 = 0$ is of the form
$$\begin{bmatrix} 0 \\ a \\ b \end{bmatrix}, \begin{bmatrix} 0 \\ c \\ d \end{bmatrix},$$
where $a, b, c, d \in \mathbb{C}$ are any numbers such that $(a, b) \neq (0, 0)$. A canonical set of Jordan chains of $P(\lambda)$ corresponding to $\lambda_0 = 0$ is given by
$$\begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}; \quad \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix},$$
and another such set is given by
$$\begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \\ 2 \end{bmatrix}; \quad \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 2 \\ 1 \end{bmatrix}, \begin{bmatrix} -1 \\ 0 \\ 2 \end{bmatrix}, \begin{bmatrix} -2 \\ 0 \\ 0 \end{bmatrix}.$$

For the matrices

$$X_0 = \begin{bmatrix} 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 & 0 \end{bmatrix}, \quad X_1 = \begin{bmatrix} 0 & 0 & 0 & 0 & -1 & -2 \\ 1 & 0 & 1 & 2 & 0 & 0 \\ 1 & 2 & 0 & 1 & 2 & 0 \end{bmatrix}, \quad J_0 = \mathrm{diag}(J_2(0), J_4(0)),$$

both (X_0, J_0) and (X_1, J_0) are Jordan pairs of $P(\lambda)$ corresponding to $\lambda_0 = 0$. Both pairs are also finite Jordan pairs because $\lambda_0 = 0$ is the only (finite) eigenvalue of $P(\lambda)$. Finally, the two pairs (X_0, J_0) and (X_1, J_0) are similar because the nonsingular matrix

$$S = \begin{bmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 2 & 0 & 0 \\ 0 & 1 & 0 & 1 & 2 & 0 \\ 0 & 0 & 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

satisfies $X_1 = X_0 S$ and $S^{-1} J_0 S = J_0$.

4. The matrix polynomial $P(\lambda)$ of grade 2 given by

$$P(\lambda) = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \lambda^2 - \begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix} \lambda + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} \lambda^2 - 2\lambda + 1 & 0 \\ 0 & 1 \end{bmatrix}$$

has the eigenvalues 1 and ∞, both with algebraic multiplicity 2 and geometric multiplicity 1. For the matrices

$$X_F = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad J_F = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad X_\infty = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \quad J_\infty = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix},$$

(X_F, J_F) is a finite Jordan pair, and (X_∞, J_∞) is an infinite Jordan pair of $P(\lambda)$. Finally, a decomposable pair of $P(\lambda)$ is given by (X, J), where

$$X = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}, \quad J = \mathrm{diag}\left(\begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \right).$$

18.4 Linearization of Matrix Polynomials

The idea of a linearization of a matrix polynomial $P(\lambda)$ is to find, via unimodular equivalence, a linear matrix polynomial (i.e., a matrix pencil) that has the same spectral properties as $P(\lambda)$, in particular the same eigenvalues and partial multiplicities.

Linearization often is the first step in the numerical solution of polynomial eigenvalue problems. Moreover, a linearization occurs naturally in the context of ordinary differential equation systems, and in particular when one reduces the system (18.3) to first order by stacking the function $x(t)$ and its derivatives into one vector of length $n \cdot (\ell + 1)$.

Definitions:

Let $P(\lambda)$ be a matrix polynomial of grade $\ell \geq 1$ and of order n.

A matrix pencil $L(\lambda)$ of order $n\ell$ is called a **linearization** of $P(\lambda)$, if there exist unimodular matrix polynomials $E(\lambda)$ and $F(\lambda)$ of order $n\ell$ such that

$$E(\lambda)L(\lambda)F(\lambda) = \begin{bmatrix} P(\lambda) & 0 \\ 0 & I_{n(\ell-1)} \end{bmatrix}.$$

If additionally $\operatorname{rev} L(\lambda)$ is a linearization of $\operatorname{rev} P(\lambda)$, then $L(\lambda)$ is called a **strong linearization** of $P(\lambda)$.

The set $\mathcal{N}(P) := \{x(\lambda) \in F(\lambda)^n : P(\lambda)x(\lambda) \equiv 0\}$, where $F(\lambda)$ denotes the field of rational functions over F, is called the **(right) null space** of $P(\lambda)$.

Let $P(\lambda) = \sum_{j=0}^{\ell} A_j \lambda^j$ be a matrix polynomial of order n with $A_\ell \neq 0$ and $\ell \geq 2$. The two **companion pencils** of $P(\lambda)$ are

$$C_1(\lambda) := \begin{bmatrix} A_\ell & & & \\ & I_n & & \\ & & \ddots & \\ & & & I_n \end{bmatrix} \lambda - \begin{bmatrix} -A_{\ell-1} & -A_{\ell-2} & \cdots & -A_0 \\ I_n & 0 & \cdots & 0 \\ & \ddots & \ddots & \vdots \\ 0 & & I_n & 0 \end{bmatrix}$$

and

$$C_2(\lambda) := \begin{bmatrix} A_\ell & & & \\ & I_n & & \\ & & \ddots & \\ & & & I_n \end{bmatrix} \lambda - \begin{bmatrix} -A_{\ell-1} & I_n & & 0 \\ -A_{\ell-2} & 0 & \ddots & \\ \vdots & \vdots & \ddots & I_n \\ -A_0 & 0 & \cdots & 0 \end{bmatrix}.$$

Furthermore, define

$$M_\ell := \begin{bmatrix} A_\ell & 0 \\ 0 & I_{n(\ell-1)} \end{bmatrix}, \quad M_0 := \begin{bmatrix} I_{n(\ell-1)} & 0 \\ 0 & -A_0 \end{bmatrix},$$

$$M_j := \begin{bmatrix} I_{n(\ell-j-1)} & 0 & 0 & 0 \\ 0 & -A_j & I_n & 0 \\ 0 & I_n & 0 & 0 \\ 0 & 0 & 0 & I_{n(j-1)} \end{bmatrix}, \quad j = 1, \ldots, \ell-1.$$

A **Fiedler pencil** of $P(\lambda)$ is a matrix pencil of the form

$$M_\ell \lambda - M_{i_0} M_{i_1} \cdots M_{i_{\ell-1}},$$

where $(i_0, i_1, \ldots, i_{\ell-1})$ is any permutation of $(0, 1, \ldots, \ell-1)$.

Facts:

1. [GLR82, Theorem 1.7] A matrix pencil $I\lambda - T$ with $T \in \mathbb{C}^{m\times m}$ is a linearization of some monic matrix polynomial over $\mathbb{C}$ of degree ℓ and order n if and only if
$$m = n\ell \quad \text{and} \quad \max_{\lambda\in\mathbb{C}} \dim \ker (I\lambda - T) \leq n.$$
2. [DDM09] A matrix pencil $L(\lambda)$ of order $n\ell$ is a linearization of a matrix polynomial $P(\lambda)$ of grade ℓ and order n if and only if $\dim \mathcal{N}(P) = \dim \mathcal{N}(L)$, and $P(\lambda)$ and $L(\lambda)$ have the same elementary divisors and hence the same partial multiplicities in every finite eigenvalue.
3. [DDM09] A matrix pencil $L(\lambda)$ of order $n\ell$ is a strong linearization of a matrix polynomial $P(\lambda)$ of grade ℓ and order n if and only if $\dim \mathcal{N}(P) = \dim \mathcal{N}(L)$, and $P(\lambda)$ and $L(\lambda)$ have the same elementary divisors and hence the same partial multiplicities in every eigenvalue, including the eigenvalue ∞.
4. [GKL88] Any two strong linearizations of a regular matrix polynomial over $\mathbb{C}$ are strictly equivalent.

5. [LP06] Let $P(\lambda)$ be a regular matrix polynomial over $\mathbb{C}$ with the eigenvalue ∞ of algebraic multiplicity $s > 0$ and let $s = \sum_{j=1}^{p} k_j$ be any partition of s into positive integers. Then there exists a linearization $L(\lambda)$ of $P(\lambda)$ which preserves the partial multiplicities of all finite eigenvalues of $P(\lambda)$ and has an eigenvalue at infinity with p elementary divisors of degrees $k_1, \ldots, k_p$.
6. [GKL88] (companion pencils and $F = \mathbb{C}$), [AV04] (regular case and $F = \mathbb{C}$), [DDM10] (general case) Let $P(\lambda) = \sum_{j=0}^{\ell} A_j\lambda^j$ be a matrix polynomial of order n (regular or singular) over an arbitrary field F with $A_\ell \neq 0$ and $\ell \geq 2$. Then any Fiedler pencil of $P(\lambda)$ is a strong linearization of $P(\lambda)$. In particular, the two companion pencils

$$C_1(\lambda) = M_\ell\lambda - M_{\ell-1}M_{\ell-2}\cdots M_0 \quad \text{and} \quad C_2(\lambda) = M_\ell\lambda - M_0M_1\cdots M_{\ell-1}$$

are Fiedler pencils and thus strong linearizations of $P(\lambda)$.
7. [MMM06], [HMM06], [LP07] (case $\det A_\ell \neq 0$) Let $P(\lambda) = \sum_{j=0}^{\ell} A_j\lambda^j$ be a regular matrix polynomial over $\mathbb{C}$ with $\ell \geq 2$. Define

$$\mathcal{L}_j := \begin{bmatrix} 0 & \ldots & 0 & A_\ell \\ \vdots & \iddots & A_\ell & A_{\ell-1} \\ 0 & \iddots & \iddots & \vdots \\ A_\ell & A_{\ell-1} & \ldots & A_{\ell-j+1} \end{bmatrix}, \quad \mathcal{U}_j := \begin{bmatrix} A_{j-1} & \ldots & A_1 & A_0 \\ \vdots & \iddots & A_0 & 0 \\ A_1 & \iddots & \iddots & \vdots \\ A_0 & 0 & \ldots & 0 \end{bmatrix}, \quad X_j := \begin{bmatrix} \mathcal{L}_j & 0 \\ 0 & -\mathcal{U}_{\ell-j} \end{bmatrix},$$

for $j = 0, 1, \ldots, \ell$, where $\mathcal{L}_0$ and $\mathcal{U}_0$ are understood to be void. Furthermore, let $\nu_1, \ldots, \nu_\ell \in \mathbb{C}$. Then the matrix pencil

$$\left(\sum_{j=1}^{\ell} \nu_j X_j\right)\lambda - \left(\sum_{j=0}^{\ell-1} \nu_{j+1} X_j\right) \tag{18.5}$$

is a strong linearization of $P(\lambda)$ if and only if no eigenvalue of $P(\lambda)$ is a root of the polynomial $p(\lambda) := \sum_{j=1}^{\ell} \nu_j\lambda^{\ell-j}$, where by convention ∞ is regarded as a root of $p(\lambda)$ if $\nu_1 = 0$.

Examples:

1. The matrix pencil $P(\lambda) = 0\lambda + I_s$ has the eigenvalue ∞ with algebraic multiplicity s. Let $s = \sum_{j=1}^{p} k_j$ be a partition of s into positive integers and define

$$E(\lambda) = \operatorname{diag}\bigl(J_{k_1}(0), \ldots, J_{k_p}(0)\bigr)\lambda + I_s.$$

Then $E(\lambda)$ is a unimodular matrix polynomial as $\det E(\lambda) \equiv 1$. Thus, the matrix pencil $L(\lambda) := E(\lambda)P(\lambda) = E(\lambda)$ is a linearization of $P(\lambda)$ and has p infinite elementary divisors of degrees $k_1, \ldots, k_p$. Unless $p = 1$, $L(\lambda)$ is not a strong linearization of $P(\lambda)$.
2. Let $P(\lambda) = A_3\lambda^3 + A_2\lambda^2 + A_1\lambda + A_0$ be of order n. Then the two companion pencils have the forms

$$C_1(\lambda) = \begin{bmatrix} A_3 & 0 & 0 \\ 0 & I_n & 0 \\ 0 & 0 & I_n \end{bmatrix}\lambda - \begin{bmatrix} -A_2 & -A_1 & -A_0 \\ I_n & 0 & 0 \\ 0 & I_n & 0 \end{bmatrix}, \quad C_2(\lambda) = \begin{bmatrix} A_3 & 0 & 0 \\ 0 & I_n & 0 \\ 0 & 0 & I_n \end{bmatrix}\lambda - \begin{bmatrix} -A_2 & I_n & 0 \\ -A_1 & 0 & I_n \\ -A_0 & 0 & 0 \end{bmatrix}.$$

Other Fiedler pencils can be constructed from

$$M_3 = \begin{bmatrix} A_3 & 0 & 0 \\ 0 & I_n & 0 \\ 0 & 0 & I_n \end{bmatrix}, \quad M_2 = \begin{bmatrix} -A_2 & I_n & 0 \\ I_n & 0 & 0 \\ 0 & 0 & I_n \end{bmatrix}, \quad M_1 = \begin{bmatrix} I_n & 0 & 0 \\ 0 & -A_1 & I_n \\ 0 & I_n & 0 \end{bmatrix}, \quad M_0 = \begin{bmatrix} I_n & 0 & 0 \\ 0 & I_n & 0 \\ 0 & 0 & -A_0 \end{bmatrix}.$$

So, for example,

$$M_3\lambda - M_2M_0M_1 = \begin{bmatrix} A_3 & 0 & 0 \\ 0 & I_n & 0 \\ 0 & 0 & I_n \end{bmatrix} \lambda - \begin{bmatrix} -A_2 & -A_1 & I_n \\ I_n & 0 & 0 \\ 0 & -A_0 & 0 \end{bmatrix}$$

is a strong linearization of $P(\lambda)$.

3. Let $P(\lambda) = A_2\lambda^2 + A_1\lambda + A_0$ be regular and of order n. Then, in the notation of Fact 7,

$$X_2 = \mathcal{L}_2 = \begin{bmatrix} 0 & A_2 \\ A_2 & A_1 \end{bmatrix}, \quad X_1 = \begin{bmatrix} \mathcal{L}_1 & 0 \\ 0 & -\mathcal{U}_1 \end{bmatrix} = \begin{bmatrix} A_2 & 0 \\ 0 & -A_0 \end{bmatrix}, \quad X_0 = -U_2 = -\begin{bmatrix} A_1 & A_0 \\ A_0 & 0 \end{bmatrix}.$$

Thus, the matrix pencil

$$(\nu_1X_1 + \nu_2X_2)\,\lambda - (\nu_1X_0 + \nu_2X_1) = \begin{bmatrix} \nu_1A_2 & \nu_2A_2 \\ \nu_2A_2 & \nu_2A_1 - \nu_1A_0 \end{bmatrix} \lambda - \begin{bmatrix} \nu_2A_2 - \nu_1A_1 & -\nu_1A_0 \\ -\nu_1A_0 & -\nu_2A_0 \end{bmatrix}$$

is a strong linearization of $P(\lambda)$ if and only if no root of $p(\lambda) = \nu_1\lambda + \nu_2$ is an eigenvalue of $P(\lambda)$.

For $\nu_1 = 1$ and $\nu_2 = 0$, the matrix pencil

$$\begin{bmatrix} A_2 & 0 \\ 0 & -A_0 \end{bmatrix} \lambda - \begin{bmatrix} -A_1 & -A_0 \\ -A_0 & 0 \end{bmatrix} \tag{18.6}$$

is a strong linearization of $P(\lambda)$ if and only if $\det A_0 \neq 0$, i.e., $\lambda_0 = 0$ is not an eigenvalue of $P(\lambda)$ (since the only root of $p(\lambda) = \nu_1\lambda + \nu_2 = \lambda$ is 0).

For $\nu_1 = 0$ and $\nu_2 = 1$, the matrix pencil

$$\begin{bmatrix} 0 & A_2 \\ A_2 & A_1 \end{bmatrix} \lambda - \begin{bmatrix} A_2 & 0 \\ 0 & -A_0 \end{bmatrix} \tag{18.7}$$

is a strong linearization of $P(\lambda)$ if and only if $\det A_2 \neq 0$, i.e., $\lambda_0 = \infty$ is not an eigenvalue of $P(\lambda)$ (since the only root of $p(\lambda) = \nu_1\lambda + \nu_2 \equiv 1$ by convention is ∞).

18.5 Hermitian Matrix Polynomials

This section deals with an important class of matrix polynomials with symmetry structures, namely the matrix polynomials over $\mathbb{C}$ that have Hermitian coefficients. Details on the real symmetric case can be found in [LZ12].

Definitions:

Let $P(\lambda)$ be a matrix polynomial of order n over $\mathbb{C}$.

The **adjoint** of $P(\lambda)$ is the matrix polynomial

$$P^*(\lambda) := \sum_{j=0}^{\ell} A_j^*\lambda^j,$$

and $P(\lambda)$ is called **Hermitian** (or **self-adjoint**), if $P(\lambda) = P^*(\lambda)$, i.e., if $A_j = A_j^*$ for $j = 0, 1, \ldots, \ell$.

The set $W(P) := \{\lambda \in \mathbb{C} : \mathbf{x}^*P(\lambda)\mathbf{x} = 0$ for some nonzero $\mathbf{x} \in \mathbb{C}^n\}$ is called the **numerical range** of $P(\lambda)$.

Facts:

1. [GLR82, p. 276] For $A \in \mathbb{C}^{n\times n}$, the numerical range of the matrix pencil $I\lambda - A$ is equal to the field of values of A. Hence for Hermitian A, the set $W(I\lambda - A)$ is a closed real interval (namely the convex hull of the eigenvalues of A). For a general matrix polynomial $P(\lambda)$ over $\mathbb{C}$, the set $W(P)$ is closed and contains all eigenvalues of $P(\lambda)$, but $W(P)$ may not be convex or compact (even when $P(\lambda)$ is Hermitian).
2. [GLR82, Lemma 10.2] If $\lambda_0 \in \mathbb{C}$ is an eigenvalue of a monic Hermitian matrix polynomial $P(\lambda)$, then $\overline{\lambda}_0$ is also an eigenvalue of $P(\lambda)$ with the same partial multiplicities.
3. [GLR82, Theorem 10.15] Let $P(\lambda)$ be a monic Hermitian matrix polynomial and let $\lambda_0 \in W(P)$ be in the closure of the complement of $W(P)$, i.e., there exists a sequence $(\lambda_n)_{n\geq 1}$ of real numbers with $\lambda_n \notin W(P)$ and $\lim_{n\to\infty} \lambda_n = \lambda_0$. Then λ_0 is an eigenvalue of $P(\lambda)$.
4. [GLR82, Corollary 10.17] A monic Hermitian matrix polynomial has no real eigenvalues if and only if $W(P) \cap \mathbb{R} = \emptyset$.
5. [GLR05, Theorem 12.3.3] The following are equivalent for a Hermitian matrix polynomial $P(\lambda)$ of order n with a nonsingular leading coefficient:
   (a) $\mathbf{x}^*P(\lambda)\mathbf{x} \geq 0$ for all $\mathbf{x} \in \mathbb{C}^n$ and $\lambda \in \mathbb{R}$.
   (b) The leading coefficient of $P(\lambda)$ is positive definite and all elementary divisors of $P(\lambda)$ corresponding to real eigenvalues (if any) have even degrees.
   (c) $P(\lambda) = Q^*(\lambda)Q(\lambda)$ for some matrix polynomial $Q(\lambda)$ of the same order as $P(\lambda)$.
6. [HMT09] Let $P(\lambda) = \sum_{j=0}^{\ell} A_j\lambda^j$ be a regular Hermitian matrix polynomial of order n with $\ell \geq 1$ and a positive definite leading coefficient A_ℓ. Then the following are equivalent:
   (a) For every nonzero vector $\mathbf{x} \in \mathbb{C}^n$ the scalar equation $\mathbf{x}^*P(\lambda)\mathbf{x} = 0$ has ℓ distinct real roots. (Hence the eigenvalues of $P(\lambda)$ are real.)
   (b) There exist real numbers $\mu_1 > \mu_2 > \cdots > \mu_{\ell-1}$ such that for $j = 1, \ldots, \ell-1$ the (Hermitian) matrices $(-1)^jP(\mu_j) \in \mathbb{C}^{n\times n}$ are positive definite.

   Matrix polynomials that are characterized by these equivalent properties are called *hyperbolic*.
7. [LR94] The following are equivalent for a Hermitian matrix polynomial $P(\lambda)$ of order n and degree 2:
   (a) $W(P) \subseteq \mathbb{R}$.
   (b) $4(\mathbf{x}^*A_0\mathbf{x})(\mathbf{x}^*A_2\mathbf{x}) \leq (\mathbf{x}^*A_1\mathbf{x})^2$ for all $\mathbf{x} \in \mathbb{C}^n$ with $\mathbf{x}^*\mathbf{x} = 1$.
   (c) For every $\mathbf{x} \in \mathbb{C}^n$ with $\mathbf{x}^*\mathbf{x} = 1$ there exists a $\widehat{\lambda} \in \mathbb{R}$ such that $\mathbf{x}^*P(\widehat{\lambda})\mathbf{x} \leq 0$.

   If the leading coefficient A_2 is positive definite, then these conditions are equivalent to the following: There exists a $\widehat{\lambda} \in \mathbb{R}$, such that $-P(\widehat{\lambda})$ is positive semidefinite.
8. [HMM06, Theorem 6.2] Let $P(\lambda) = \sum_{j=0}^{\ell} A_j\lambda^j$ be a regular Hermitian matrix polynomial over $\mathbb{C}$ with $\ell \geq 2$. Then the pencil in Eq. (18.5) is Hermitian if and only if $\nu_1, \ldots, \nu_\ell \in \mathbb{R}$.

Examples:

1. $P(\lambda) = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}\lambda + \begin{bmatrix} 0 & i \\ -i & 0 \end{bmatrix}$ is a Hermitian matrix polynomial with the non-compact numerical range $W(P) = \mathbb{R}$.
2. [LR94] For $n \geq 2$ consider $P(\lambda) = I_n\lambda^2 + \epsilon B\lambda + B$, where $\epsilon > 0$ is a real parameter and $B \in \mathbb{C}^{n\times n}$ is Hermitian positive definite (but not a scalar multiple of I_n). Then $P(\lambda)$ is a

Hermitian matrix polynomial, and for sufficiently small ϵ its numerical range $W(P)$ is the union of two disjoint arcs lying on the circle $\{(\eta,\xi) \in \mathbb{R}^2 : \eta^2 + \xi^2 + 2\xi\epsilon^{-1} = 0\}$ in $\mathbb{C}$. In particular, $W(P)$ consists of two disjoint components both of which are nonconvex.

3. If $P(\lambda) = A_2\lambda^2 + A_1\lambda + A_0$ is Hermitian, then the two pencils in Eq. (18.6) and Eq. (18.7) are Hermitian as well.

Acknowledgment

The authors thank Steve Mackey for careful reading of an earlier version of this chapter and for many helpful suggestions.

19.4 Algebraic Riccati Equations 19-8
References 19-12

Beatrice Meini
Università di Pisa

Matrix equations are equations involving matrices, both in the unknown and in the formal expression of the equation. They appear in various guises: linear and polynomial matrix equations, in the form of matrix power series, of rational functions, and more. The interest is both in the theoretical properties and in the numerical solution, since many matrix equations arise in the modeling of real world problems. In this chapter, after giving an introduction with several examples, we analyze linear matrix equations, polynomial matrix equations, and algebraic Riccati equations.

Unless differently specified, all the matrices in this chapter are complex.

19.1 Introduction

Definitions:

In its greatest generality a **matrix equation** is an equation of the form $F(X) = 0$, where the unknown X belongs to $\mathbb{C}^{m\times n}$ and F is a function $F : \mathbb{C}^{m\times n} \to \mathbb{C}^{k\times p}$.

However, the equations treated in this chapter are all specified by finite formulas involving the unknown X along with other matrices and matrix functions combined by the usual matrix operations. In addition, to avoid under- or over-determined equations it is assumed that F maps into $\mathbb{C}^{m\times n}$, or at least that $mn = kp$.

Facts:

What follows is an incomplete list of matrix equations, with some properties and references to related literature.

1. Given the matrices $A_i \in \mathbb{C}^{k\times m}$, $B_i \in \mathbb{C}^{n\times p}$, $i = 1, \ldots, \ell$, and $Q \in \mathbb{C}^{k\times p}$, define $F(X) = \sum_{i=1}^{\ell} A_i X B_i - Q$, for $X \in \mathbb{C}^{m\times n}$. The equation $F(X) = 0$ is a matrix equation, linear in the unknown X. In Section 19.2 we will treat in detail this class of matrix equations.
2. Let $p(z)$ be a polynomial with scalar coefficients, say $p(z) = \sum_{i=0}^{\ell} a_i z^i$, with $a_\ell = 1$. The matrix equation $p(X) = 0$ takes the form $\sum_{i=0}^{\ell} a_i X^i = 0$.

   (a) If $p(X) = 0$, then $p(SXS^{-1}) = Sp(X)S^{-1} = 0$. Therefore, if X is a solution, then any matrix similar to X is a solution as well.
   (b) The set of solutions of $p(X) = 0$ is precisely the set of matrices X such that their minimal polynomial $q_X(z)$ divides $p(z)$. In particular, there are finitely many solutions (up to similarity transformations), since there are only finitely many divisors of $p(z)$ (see [HJ91, Sect. 6.4] and Example 1).

3. Polynomial matrix equations, which are discussed in detail in Section 19.3, are equations of the kind $\sum_{i=0}^{\ell} A_i X^i = 0$ (with $\ell \geq 0$), where the coefficients A_i, $i \geq 0$, and the unknown X are $m \times m$ matrices. With these equations we may associate the matrix polynomial $A(z) = \sum_{i=0}^{\ell} z^i A_i$.
   (a) Unlike the equations of Fact 2, the coefficients of the matrix equation do not necessarily commute with the unknown.
   (b) The problem of solving the matrix equation is related to the problem of finding the eigenvalues of $A(z)$, i.e., the roots of $\det A(z)$.
   (c) Polynomial matrix equations may have a finite number of solutions, an infinite number of solutions, or no solution.
   (d) Applications range from queuing models and Markov chains, analysis of vibrations, to problems in dynamics and PDE (see, for instance, [LR99, Lan02, GHT08, NV10, TM01, MMM06]).
4. Polynomial matrix equations can be extended to power series matrix equations, i.e., to equations of the form $\sum_{i=0}^{\infty} A_i X^i = 0$, where the coefficients A_i, $i \geq 0$, and the unknown X are $m \times m$ matrices. An example of application is the analysis of Markov chains of M/G/1-type (see [Neu89] and Example 72.1.4 for the definition of M/G/1-type Markov chains). For this example, the block coefficients are real matrices such that $A_1 = I - B_1$, $A_i = -B_i$ for $i \neq 1$, where B_i, for $i \geq 0$, are nonnegative matrices such that $\sum_{i \geq 0} B_i$ is stochastic. Under these assumptions, there exists a unique minimal nonnegative solution G, i.e., such that $G \leq Y$ for any other possible nonnegative solution Y, where the ordering is component-wise; moreover, $\rho(G) \leq 1$. We refer the reader to the books [Neu89, BLM05] for theoretical properties and algorithms.
5. Several matrix equations can be represented as $f(X) = A$, where A, X are $m \times m$ matrices, $f(z)$ is a scalar valued function, and $f(X)$ is a primary matrix function (see Chapter 17). By using the theory of matrix functions, it is possible to give sufficient conditions for the existence of a solution that is itself a primary matrix function of A; however, there might exist other solutions that are not primary functions of A (see Examples 2 and 3). We refer to [HJ91, Sect. 6.4] for a discussion on these issues and to [Hig08] and Chapter 17 for the theory on matrix functions.
6. Algebraic Riccati equations are a class of matrix equations that model a variety of different problems of the real world. Continuous-time algebraic Riccati equations are quadratic matrix equations, while discrete-time algebraic Riccati equations are in the form of a rational function. In Section 19.4 we will treat in detail this class of equations.
7. Equation

$$X - C^* X^{-1} C - Q = 0 \tag{19.1}$$

   where Q is a $m \times m$ positive definite matrix, arises in the analysis of stationary Gaussian reciprocal processes over a finite interval.

   (a) [FL96] There always exists a unique positive definite solution X_+, which is the maximal one and, if C is nonsingular, there exists a unique negative definite solution X_-, which is the minimal one. Here maximal and minimal mean that $X_- \preceq X \preceq X_+$ for any other possible Hermitian solution X, where the ordering is the Loewner ordering for Hermitian matrices.
   (b) Numerical methods for its solution can be found in [GL99, Mei02, FG08, IHU05].
   (c) Equation (19.1) is often studied with the equation $X + C^* X^{-1} C - Q = 0$, where Q is positive definite. The latter equation is a special discrete-time algebraic Riccati equation and will be treated in Section 19.4.

8. The solutions of certain matrix equations can be expressed by means of the invariant subspace of suitable matrices. For instance, given $A \in \mathbb{C}^{m\times m}$, X solves the equation $X^2 - A = 0$ if and only if $\begin{bmatrix} 0 & I \\ A & 0 \end{bmatrix} \begin{bmatrix} I \\ X \end{bmatrix} = \begin{bmatrix} I \\ X \end{bmatrix} X$, i.e., the columns of $\begin{bmatrix} I \\ X \end{bmatrix}$ span an invariant subspace for the matrix $\begin{bmatrix} 0 & I \\ A & 0 \end{bmatrix}$.
9. The equation $\sum_{i=1}^{\ell} \log(A_i^{-1} X) = 0$, where A_i, $i = 1, \ldots, \ell$, are real positive definite matrices, is an example of a non-algebraic matrix equation. This equation has a unique positive definite solution (see [Bha07, Chap. 6]), and appears in the definition of the matrix geometric mean (see [Moa06]).
10. The equation $X + \sum_{i=1}^{\ell} A_i X^{-1} D_i - C = 0$, where $\ell \geq 2$, all the matrices are real of size $m \times m$, and A_i, D_i, $i = 1, \ldots, \ell$, $I - C$ are nonnegative, arises in the study of tree-like stochastic processes. The solution of interest is an M-matrix (see [BLM03, BLM05]).

Examples:

1. The equation $X^2 - 6X + 9 = 0$ is in the form $p(X) = 0$, where $p(z) = z^2 - 6z + 9 = (z-3)^2$. The possible divisors of $p(z)$ are $(z - 3)$ and $(z - 3)^2$. Therefore, the solutions are matrices X such that their minimal polynomial is either $q_X(z) = z - 3$, or $q_X(z) = (z - 3)^2$. In the former case, $X = 3I$. In the latter case, the Jordan canonical form of X must contain at least one Jordan block $J_2(3)$, and the rest of the Jordan canonical form must be formed by $J_2(3)$ blocks or $J_1(3)$ blocks.
2. Given an integer $p \geq 2$ and a matrix $A \in \mathbb{C}^{m\times m}$, the equation $X^p = A$ is of the form $f(X) = A$, where $f(z) = z^p$ and $f(X)$ is the primary matrix function. Every solution $X \in \mathbb{C}^{m\times m}$ is a p-th root of A. If A does not have eigenvalues on the closed negative real axis (for instance, if A is positive stable), then there exist solutions that are primary functions of A. However, there might also exist solutions that are not primary functions of A. For instance, if $p = 2$ and $A = I_2$, the matrices $X = I_2$ and $X = -I_2$ are solutions of $X^2 = A$, which are primary functions of A; however, the matrices $X = \begin{bmatrix} 2 & -1 \\ 3 & -2 \end{bmatrix}$ and $X = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$ are solutions, but they are not primary functions of A (see Chapter 17, [HJ91, Sect. 6.4] and [Hig08, Chap. 1]).
3. The logarithm of a square matrix A, when it exists, can be defined as a solution of the matrix equation $e^X - A = 0$. If A is nonsingular, there exists a solution that is a polynomial in A (see Chapter 17, [Hig08, Chap. 1] and [HJ91, Sect. 6.4]).

19.2 Linear Matrix Equations

Linear matrix equations are equations that are linear in the unknown X. Among linear matrix equations, special attention is devoted to Sylvester, Lyapunov, and Stein equations.

We recall their definitions, theoretical properties, and some numerical methods for their solution.

Definitions:

A **linear matrix equation** is a matrix equation of the kind

$$\sum_{i=1}^{\ell} A_i X B_i - Q = 0, \tag{19.2}$$

where $\ell \geq 1$, $Q \in \mathbb{C}^{k\times p}$, $A_i \in \mathbb{C}^{k\times m}$, $B_i \in \mathbb{C}^{n\times p}$, for $i = 1, \ldots, \ell$, and $X \in \mathbb{C}^{m\times n}$ is the unknown.

A linear matrix equation of the kind

$$AX + XB - Q = 0, \tag{19.3}$$

where $A \in \mathbb{C}^{m\times m}$, $B \in \mathbb{C}^{n\times n}$, $Q \in \mathbb{C}^{m\times n}$, and $X \in \mathbb{C}^{m\times n}$, is called a **Sylvester equation**.

If $\ell = 2$, then the linear matrix equation (19.2) takes the form

$$A_1 X B_1 + A_2 X B_2 - Q = 0$$

and is called a **generalized Sylvester equation**.

If $m = n$, $B = A^*$, and $Q = Q^*$, then the Sylvester equation (19.3) takes the form

$$AX + XA^* - Q = 0 \tag{19.4}$$

and is called a **Lyapunov equation**.

The equation

$$AXB^* + BXA^* - Q = 0, \quad A, B, Q, X \in \mathbb{C}^{m\times m},$$

where $Q = Q^*$, is called a **generalized Lyapunov equation**.

The matrix equation

$$X - AXB - Q = 0, \quad A \in \mathbb{C}^{m\times m},\ B \in \mathbb{C}^{n\times n},\ Q, X \in \mathbb{C}^{m\times n}, \tag{19.5}$$

is called a **Stein equation**.

Facts:

Facts requiring proof for which no specific reference is given can be found in [HJ91, Chap. 4] and [LT85, Chap. 12].

1. By using the vec function, the linear matrix equation (19.2) can be written as the $(pk) \times (mn)$ linear system

$$\left(\sum_{i=1}^{\ell} B_i^T \otimes A_i\right) \boldsymbol{x} = \boldsymbol{q}, \tag{19.6}$$

   where $\boldsymbol{q} = \mathrm{vec}(Q)$, $\boldsymbol{x} = \mathrm{vec}(X)$ (see Fact 11.4.15). Hence, existence and uniqueness properties of the solution of Eq. (19.2) can be derived from the properties of the linear system (19.6).
2. For Fact 1, the Sylvester equation (19.3) can be written as the $(mn) \times (mn)$ linear system

$$(I_n \otimes A + B^T \otimes I_m)\boldsymbol{x} = \boldsymbol{q}, \quad \boldsymbol{x} = \mathrm{vec}(X),\ \boldsymbol{q} = \mathrm{vec}(Q). \tag{19.7}$$

   The matrix in Eq. (19.7) is nonsingular if and only if the matrices A and $-B$ have no common eigenvalue (cf. Fact 11.4.18). Therefore, the Sylvester equation (19.3) has a unique solution if and only if $\sigma(A) \cap \sigma(-B) = \emptyset$.

3. The Sylvester equation (19.3) is equivalent to the equation

$$\begin{bmatrix} A & -Q \\ 0 & -B \end{bmatrix} = \begin{bmatrix} I_m & X \\ 0 & I_n \end{bmatrix} \begin{bmatrix} A & 0 \\ 0 & -B \end{bmatrix} \begin{bmatrix} I_m & X \\ 0 & I_n \end{bmatrix}^{-1}.$$

   Moreover, Eq. (19.3) has a solution X if and only if the matrices $\begin{bmatrix} A & -Q \\ 0 & -B \end{bmatrix}$ and $\begin{bmatrix} A & 0 \\ 0 & -B \end{bmatrix}$ are similar [GLR82, Theorem S2.1].
4. The Lyapunov equation (19.4) has a unique solution if and only if the matrix A has no pairs of eigenvalues of the form $(\lambda, -\bar{\lambda})$; in that case, the unique solution X is Hermitian.
   (a) If A is negative (positive) stable, then Eq. (19.4) has a unique solution, which is Hermitian.

   (b) If A is negative stable and Q is positive definite, then the unique solution X is negative definite, and is given by $X = -\int_0^\infty e^{At} Q e^{A^* t} dt$.
5. The Stein equation (19.5) has a unique solution if and only if $\lambda\mu \neq 1$ for any pair λ, μ of eigenvalues of A and B, respectively.
   (a) [LT85, Sect. 12.3] If $\rho(A)\rho(B) < 1$ then Eq. (19.5) has a unique solution, given by $X = \sum_{i=0}^{\infty} A^i Q B^i$.

   (b) If $B = A^*$, $Q = Q^*$, and if $\lambda\mu \neq 1$ for any pair λ, μ of eigenvalues of A, then the unique solution X is Hermitian. If $B = A^*$, $\rho(A) < 1$, $Q = Q^*$, and Q is positive definite, then the unique solution X is positive definite.
6. Numerical solution of the Sylvester and Lyapunov equations
   (a) An obvious but inefficient algorithm for solving the Sylvester equation (19.3) is to solve the $(mn) \times (mn)$ linear system (19.7) by means of general solution algorithms like the Gaussian elimination with partial pivoting with the cost of $O((mn)^3)$ ops.

   (b) [BS72] A more effective algorithm is the Bartels and Stewart algorithm, which consists first in transforming the matrices A and B^T into Schur (quasi)triangular form, and then in solving a (quasi)triangular linear system; if $m = n$, the overall cost is around $60n^3$ ops.

   (c) [GNV79], [Sim96, Sect. 2.3.1] A variant of this algorithm by Golub, Nash, and Van Loan consists of transforming the matrix A into upper Hessenberg form and the matrix B^T into Schur (quasi)triangular form; this leads to a saving in the computational cost if $m > n$.

   (d) In the case where the Lyapunov equation has large-sized coefficients, where A is sparse and Q has low rank, specific algorithms can be designed, based for instance on Krylov subspace techniques [Saa90] and on ADI (Alternate Direction Implicit) iteration [Wac88]. These algorithms rely on the property that the solution can be well approximated by a low-rank matrix (see, for instance, [BLP08, DKS11]).

Examples:

1. Let $A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ and $B = \begin{bmatrix} -1 & 3 \\ 0 & 5 \end{bmatrix}$, and consider that Sylvester equation $AX + XB = Q$. Observe that $\sigma(A) \cap \sigma(-B) = \{-1\}$. The matrix $V = I_2 \otimes A + B^T \otimes I_2$ has rank 3 and

the vector in the kernel is, up to a multiplicative constant, the vector $\boldsymbol{x} = [2 \;\; 2 \; -1 \; -1]^T$. Therefore, the matrix $X = \begin{bmatrix} 2 & -1 \\ 2 & -1 \end{bmatrix}$ solves the homogeneous equation $AX + XB = 0$. The matrix equation $AX + XB = \begin{bmatrix} -2 & 18 \\ 2 & 0 \end{bmatrix}$ has an infinite number of solutions, one of which is, for instance, $X = \begin{bmatrix} 3 & 2 \\ 1 & -1 \end{bmatrix}$. The matrix equation $AX + XB = \begin{bmatrix} 8 & -4 \\ 8 & -4 \end{bmatrix}$ does not have a solution.

19.3 Polynomial Matrix Equations

Among nonlinear matrix equations, polynomial matrix equations deserve particular attention for their several applications and for their interesting theoretical and numerical properties.

Definitions:

Let $\ell \geq 2$, and let $A_i \in \mathbb{C}^{m \times m}$, $i = 0, 1, \ldots, \ell$. The matrix equation

$$\sum_{i=0}^{\ell} A_i X^i = 0, \quad X \in \mathbb{C}^{m \times m} \tag{19.8}$$

is called **polynomial matrix equation (PME)**.

The matrix coefficients A_i, $i = 0, 1, \ldots, \ell$, define the **matrix polynomial** $A(z) = \sum_{i=0}^{\ell} z^i A_i$.

If $\ell = 2$ and A_2 is different from the null matrix, the matrix equation (19.8) is called **quadratic matrix equation (QME)** and becomes

$$A_0 + A_1 X + A_2 X^2 = 0, \quad X \in \mathbb{C}^{m \times m}. \tag{19.9}$$

In that case, $A(z)$ is a **quadratic matrix polynomial**.

It is important to point out that the unknown X is always on the same side with respect to the matrix coefficients; therefore, sometimes the term **unilateral** is used.

The matrix polynomial $A(z)$ is called **regular** if $\det(A(z)) \neq 0$ for at least one $z \in \mathbb{C}$.

If $A(z)$ is regular, we define the **eigenvalues** to be the solutions of the equation $\det(A(z)) = 0$.

If the degree of $a(z) = \det(A(z))$ is $m\ell - r$, with $r > 0$, then we say that $A(z)$ has r **eigenvalues at infinity**.

If λ is a finite eigenvalue of the matrix polynomial $A(z)$, we say that the vectors $\boldsymbol{v}_1, \ldots, \boldsymbol{v}_h$ form a **Jordan chain of length** h for $A(z)$ corresponding to λ if

$$\sum_{j=0}^{i} \frac{1}{j!} A^{(j)}(\lambda) \boldsymbol{v}_{i-j+1} = 0, \quad \text{for } i = 0, \ldots, h-1, \tag{19.10}$$

where $A^{(j)}(z)$ denotes the jth derivative of $A(z)$ with respect to z.

Let $L - zK$ be an $n \times n$ regular matrix pencil. An m-dimensional subspace $\mathcal{S} \subseteq \mathbb{C}^n$ is called **deflating subspace** of the pencil $L - zK$ if there exists an m-dimensional subspace $\mathcal{T} \subseteq \mathbb{C}^n$ such that

$$L\mathcal{S} \subseteq \mathcal{T}, \quad K\mathcal{S} \subseteq \mathcal{T}.$$

Facts:

A general theory on the existence and properties of the solutions of Eq. (19.8) can be found in [HK00], [GLR82, Chap. 1], [LT85, Chap. 7], [HJ91, Chap. 6].

1. Let $A(z)$ be a regular matrix polynomial. Since $a(z) = \det(A(z))$ has degree at most $m\ell$, the finite eigenvalues of $A(z)$ are at most $m\ell$ in number. If we also count the eigenvalues at infinity, the number of eigenvalues of $A(z)$ is exactly $m\ell$.
2. PMEs can have a finite number of solutions, an infinite number of solutions, or no solution (see [HJ91, Sect. 6.4], [GLR82, Hig87], and Example 1).
3. [TM01] Let G be a solution of Eq. (19.8) and let $\boldsymbol{v}$ be an eigenvector of G, corresponding to the eigenvalue λ, i.e., $G\boldsymbol{v} = \lambda\boldsymbol{v}$. Then, by multiplying Eq. (19.8) on the right by $\boldsymbol{v}$, one finds that $(\sum_{i=0}^{\ell} \lambda^i A_i)\boldsymbol{v} = 0$. Therefore, the eigenvalues/vectors of any solution G are eigenvalues/vectors of the matrix polynomial $A(z)$. For this reason, sometimes the problem of computing the solution of a PME is reduced to computing the eigenvalues of a matrix polynomial.
4. If $G = SJS^{-1}$ is the Jordan decomposition of a solution G of Eq. (19.8), then $\sum_{i=0}^{\ell} A_i S J^i = 0$. In particular, the columns of S are formed by (a subset of) Jordan chains of the matrix polynomial $A(z)$.
5. From the definition (19.10) of Jordan chains, one finds that if $V \in \mathbb{C}^{m\times h}$ is a matrix whose columns are formed by (a subset of) Jordan chains corresponding to the eigenvalue λ of $A(z)$, then

   $$A_0 V + A_1 V J_h(\lambda) + A_2 V J_h(\lambda)^2 + \cdots + A_k V J_h(\lambda)^k = 0.$$

   Equation (19.8) does not have solution if there does not exist a nonsingular $m \times m$ matrix, whose columns are formed by Jordan chains, such that $\sum_{i=0}^{\ell} A_i S J^i = 0$, where J is an $m \times m$ Jordan matrix corresponding to eigenvalues of $A(z)$.
6. [GLR82, Corollary 3.6], [Lan02], [HJ91, Sect. 6.4] If G is a solution of Eq. (19.8), then the matrix polynomial $A(z)$ can be factored as $A(z) = Q(z)(zI - G)$, for a suitable matrix polynomial $Q(z)$, which can be obtained with the Euclidean algorithm applied to $A(z)$, with $zI - G$ as the divisor.
7. Define the block $\ell \times \ell$ matrices

   $$L = \begin{bmatrix} 0 & I & & \\ & \ddots & \ddots & \\ & & 0 & I \\ -A_0 & -A_1 & \dots & -A_{\ell-1} \end{bmatrix}, \quad K = \begin{bmatrix} I & & & \\ & \ddots & & \\ & & I & \\ & & & A_\ell \end{bmatrix}.$$

   By direct inspection, one can verify that the matrix G is a solution of Eq. (19.8) if and only if

   $$LV = KVG, \quad V = \begin{bmatrix} I \\ G \\ \vdots \\ G^{\ell-1} \end{bmatrix}.$$

   Therefore, G is a solution of Eq. (19.8) if and only if the columns of the matrix V span a deflating subspace for the pencil $L - zK$.
8. [HK00, Theorem 3] All the solutions of the quadratic matrix equation (19.9) are of the form $G = Z_{21}Z_{11}^{-1} = Q_{11}T_{11}S_{11}^{-1}Q_{11}^{-1}$, where $Q^*LZ = T$, $Q^*KZ = S$ is a generalized Schur decomposition, i.e., Q and Z are unitary matrices, S and T are upper triangular, and where all the matrices are partitioned as block 2×2 matrices with $m \times m$ blocks.
9. Concerning numerical methods, Fact 7 allows us to express the solution of a PME through the deflating subspace of suitable matrix pencils. Therefore, a classical numerical method consists of computing this deflating subspace. Other classical algorithms rely on fixed point iterations or on Newton's method. More recently, iterative

algorithms based on cyclic reduction have been designed. The reader may find in [HK00, BLM05, BM09] the description of some numerical methods for general PMEs or QMEs, or for specific equations arising in Markov chains.

Examples:

1. Consider the matrix equation $X^2 - A = 0$. If $A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$, then this equation cannot have a solution. In fact, since A has zero eigenvalues, also a solution X must have zero eigenvalues. Therefore, either X is the zero matrix or X has a Jordan form of the kind $\begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$. In both cases, $X^2 = 0 \neq A$.
   If $A = I$, any involutory matrix X such that $X^2 = I$ is a solution of this equation. In particular, if $m = 2$, matrices of the form $X = \begin{bmatrix} \sin\theta & \cos\theta \\ \cos\theta & -\sin\theta \end{bmatrix}$ satisfy $X^2 = I$.
   If $A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$, then there are exactly two solutions, that is, $\begin{bmatrix} 1 & \frac{1}{2} \\ 0 & 1 \end{bmatrix}$, $\begin{bmatrix} -1 & -\frac{1}{2} \\ 0 & -1 \end{bmatrix}$.
2. PMEs arising in applications usually satisfy specific properties that guarantee the existence of solutions; moreover, the solution of interest is the one having specific spectral properties, say, the one having smallest spectral radius, or eigenvalues lying in a given region of the complex plane. The following are two examples arising in applications:
   (a) [Lan02] In overdamped vibration problems, a QME must be solved, where the matrices A_1 and A_2 are real positive definite, A_0 is real positive semidefinite, and $(\boldsymbol{x}^T A_1 \boldsymbol{x})^2 > 4(\boldsymbol{x}^T A_2 \boldsymbol{x})(\boldsymbol{x}^T A_0 \boldsymbol{x})$ for any $\boldsymbol{x} \in \mathbb{R}^m$, $\boldsymbol{x} \neq 0$. Under these assumptions, the eigenvalues of $A(z)$ are real and nonpositive, and there exists a gap between the m largest and the m smallest eigenvalues. Moreover, the QME (19.9) has at least two real solutions, one with eigenvalues that coincide with the m largest of $A(z)$, and one with eigenvalues that coincide with the m smallest of $A(z)$.

   (b) [BLM05, LR99] In Markov chains of M/G/1-type, the interest is the solution of a PME where $A_1 = I - B_1$, $A_i = -B_i$ for $i \neq 1$, and where B_i, $i \geq 0$, are real nonnegative matrices such that $\sum_{i \geq 0} B_i$ is a stochastic matrix. In Quasi-Birth and Death stochastic processes $\ell = 2$. There exists a nonnegative solution G of Eq. (19.8) such that $G \leq H$, for any other possible nonnegative solution H. Moreover, G has spectral radius at most one, and is the solution of smallest spectral radius. The matrix G is the limit, as k tends to infinity, of the sequence defined by the fixed point iteration $X_{k+1} = \sum_{i=0}^{\ell} B_i X_k^i$, $k \geq 0$, with $X_0 = 0$.

19.4 Algebraic Riccati Equations

Algebraic Riccati equations are encountered in many applications from different areas, including optimal control, queueing models, numerical solution of the transport equation, differential games, and more. We refer to the books [AFI03, BIM12, BLW91, LR95, Meh91, Sim96] for theoretical properties, applications, and algorithms.

Definitions:

A **nonsymmetric algebraic Riccati equation (NARE)** is a matrix equation of the form

$$C + XA + DX - XBX = 0, \tag{19.11}$$

where $X \in \mathbb{C}^{m \times n}$ is the unknown, and where the coefficients are $A \in \mathbb{C}^{n \times n}$, $B \in \mathbb{C}^{n \times m}$, $C \in \mathbb{C}^{m \times n}$ and $D \in \mathbb{C}^{m \times m}$.

A **continuous-time algebraic Riccati equation (CARE)** is a NARE where the block coefficients are square, i.e., $m = n$, and such that $C = C^*$, $B = B^*$, and $D = A^*$, i.e., an equation of the kind

$$C + XA + A^*X - XBX = 0. \tag{19.12}$$

A **discrete-time algebraic Riccati equation (DARE)** has the form

$$A^*XA + Q - (C + B^*XA)^*(R + B^*XB)^{-1}(C + B^*XA) - X = 0, \tag{19.13}$$

where A is an $n \times n$ matrix, B, C, Q, and R are matrices of sizes $n \times m$, $m \times n$, $n \times n$, and $m \times m$, respectively, with $R = R^*$ and $Q = Q^*$.

A solution X of the CARE (19.12) is said to be **stabilizing** if $\sigma(A - BX) \subset \mathbb{C}^-$, i.e., $A - BX$ is left stable.

Let A be an $n \times n$ matrix and B an $n \times m$ matrix. The pair (A, B) is called **stabilizable** if there exists a matrix K such that $A - KB$ is left stable.

Facts:

The following facts are classical properties, which can be found, for instance, in [BIM12, BLW91, LR95, Meh91].

1. We associate a NARE with the $(m + n) \times (m + n)$ matrix

$$H = \begin{bmatrix} A & -B \\ -C & -D \end{bmatrix}. \tag{19.14}$$

The solutions of Eq. (19.11) can be put in one-to-one correspondence with certain invariant subspaces of H. In fact, X is a solution of Eq. (19.11) if and only if

$$H \begin{bmatrix} I_n \\ X \end{bmatrix} = \begin{bmatrix} I_n \\ X \end{bmatrix} (A - BX).$$

In particular, if

$$H \begin{bmatrix} Z_1 \\ Z_2 \end{bmatrix} = \begin{bmatrix} Z_1 \\ Z_2 \end{bmatrix} W$$

for suitable $n \times n$, $m \times n$ and $n \times n$ matrices Z_1, Z_2, and W, respectively, and if Z_1 is invertible, then $X = Z_2 Z_1^{-1}$ is a solution of Eq. (19.11).

2. If X is a solution of Eq. (19.11) and H is as in Eq. (19.14), then

$$\begin{bmatrix} I_n & 0 \\ X & I_m \end{bmatrix}^{-1} H \begin{bmatrix} I_n & 0 \\ X & I_m \end{bmatrix} = \begin{bmatrix} A - BX & -B \\ 0 & -(D - XB) \end{bmatrix}.$$

Therefore, $\sigma(H) = \sigma(A - BX) \cup \sigma(XB - D)$.

3. Let us associate with the NARE (19.11) the dual equation

$$YCY + AY + YD - B = 0. \tag{19.15}$$

Similarly to the case of the NARE (19.11), a solution Y to Eq. (19.15) can be described in terms of invariant subspaces as

$$H \begin{bmatrix} Y \\ I_m \end{bmatrix} = \begin{bmatrix} Y \\ I_m \end{bmatrix} (-D - CY),$$

where H is defined in Eq. (19.14). Therefore, if X and Y are solutions of the NAREs (19.11) and (19.15), respectively, then

$$H\begin{bmatrix} I_n & Y \\ X & I_m \end{bmatrix} = \begin{bmatrix} I_n & Y \\ X & I_m \end{bmatrix}\begin{bmatrix} A-BX & 0 \\ 0 & -(D+CY) \end{bmatrix}.$$

Thus, if $\begin{bmatrix} I_n & Y \\ X & I_m \end{bmatrix}$ is nonsingular, i.e., $\det(I_m - XY) \neq 0$, then

$$\begin{bmatrix} I_n & Y \\ X & I_m \end{bmatrix}^{-1} H\begin{bmatrix} I_n & Y \\ X & I_m \end{bmatrix} = \begin{bmatrix} A-BX & 0 \\ 0 & -(D+CY) \end{bmatrix}.$$

4. In applications arising in fluid queues and in transport theory, the coefficients of the NARE (19.11) are such that

$$M = \begin{bmatrix} A & -B \\ C & D \end{bmatrix}$$

is an M_0-matrix. If M is nonsingular, or singular and irreducible, then the NARE (19.11) has a nonnegative solution $X_{\min}$ such that for any other nonnegative solution X it holds that $X_{\min} \leq X$. Moreover, $\sigma(A - BX_{\min}) \subset \mathbb{C}_0^+$.

5. In the case of a CARE (19.12), the interest is in Hermitian solutions. The matrix H, that takes the form

$$H = \begin{bmatrix} A & -B \\ -C & -A^* \end{bmatrix}, \tag{19.16}$$

is a Hamiltonian matrix, that is, it satisfies the equation $\mathrm{J}H = -H^*\mathrm{J}$, where $\mathrm{J} = \begin{bmatrix} 0 & I_n \\ -I_n & 0 \end{bmatrix}$. Among the Hermitian solution, the interest is solutions such that $\sigma(A - BX) \subset \mathbb{C}_0^-$.

6. Let H be the matrix in Eq. (19.16). Since $H = -\mathrm{J}^{-1}H^*\mathrm{J}$, the nonimaginary eigenvalues of H comes in pairs $(\lambda, -\bar{\lambda})$. If H has no purely imaginary eigenvalues and there exists a solution X such that $\sigma(A - BX) \subset \mathbb{C}^-$, then X is the unique stabilizing solution, and in particular X is Hermitian.

7. Assume that $B \succeq 0$. There exists a unique Hermitian solution X_+ of the CARE (19.12) such that $\sigma(A - BX_+) \subset \mathbb{C}_0^-$ if and only if the pair (A, B) is stabilizable and the partial multiplicities of the pure imaginary eigenvalues of H (if any) are all even.

8. Assume that $B \succeq 0$. There exists a unique Hermitian solution X_- of the CARE (19.12) such that $\sigma(A - BX_-) \subset \mathbb{C}_0^+$ if and only if the pair $(-A, B)$ is stabilizable and the partial multiplicities of the pure imaginary eigenvalues of H (if any) are all even.

9. Assume that $B \succeq 0$. Suppose that the CARE (19.12) has X_+ and X_-, defined in Facts 7 and 8, among its solutions. If X is any other Hermitian solution, then $X_- \preceq X \preceq X_+$.

10. The simple CARE $A - XB^{-1}X = 0$, where A and B are real positive definite matrices, has a unique positive definite solution, which is called the geometric mean of A and B [Bha07, Chap. 4], and is denoted by $X = A\#B$. In this special case, many explicit expressions for the solution are known, for instance $A\#B = A(A^{-1}B)^{1/2} = A^{1/2}(A^{-1/2}BA^{-1/2})^{1/2}A^{1/2}$, where $Y^{1/2}$ denotes the principal square root of Y.

11. Similarly to NARE and CARE, the solutions of DARE can be put in correspondence with suitable deflating subspaces. Consider the DARE (19.13) and assume that the matrix R is invertible. Define the matrix pencil

$$\begin{bmatrix} A - BR^{-1}C & 0 \\ -Q + C^*R^{-1}C & I \end{bmatrix} - z \begin{bmatrix} I & BR^{-1}B^* \\ 0 & (A - BR^{-1}C)^* \end{bmatrix}. \tag{19.17}$$

If X is a solution of Eq. (19.13), then the columns of $\begin{bmatrix} I_n \\ X \end{bmatrix}$ span a deflating subspace for the pencil (19.17). Conversely, if the span of $\begin{bmatrix} U \\ V \end{bmatrix}$ is a deflating subspace for the matrix pencil (19.17), where U is an $n \times n$ nonsingular matrix and V is $n \times n$, then the matrix $X = VU^{-1}$ is a solution of Eq. (19.13).
12. The equation $X + C^*X^{-1}C = Q$, where Q is positive definite, is a special DARE in which the coefficients A and R are zero matrices, and B is the identity matrix. It has application to ladder networks, dynamic programming, stochastic filtering, and statistics [AMT90]. If the function $\phi(z) = z^{-1}C^* + Q + zC$ is such that $\phi(z) \succ 0$ for $|z| = 1$, then there exists a unique maximal positive definite solution X_+ to this equation, i.e., such that $X_+ \succeq X$ for any other possible positive definite solution X; moreover, $\rho(X_+^{-1}C) < 1$. Specifically designed algorithms for its numerical solution are proposed in [ER01, FG08, Guo01, GL99, LX06, Mei02, Xu01].
13. There are several results concerning perturbation theory and conditioning of algebraic Riccati equations. Since the solution of these matrix equations can be put in correspondence with invariant subspaces of suitable matrices, the perturbation results on invariant subspaces can be used to derive perturbation results for algebraic Riccati equations, and vice versa (see Section 20.3, [GLR06, Sect. 17.9], [KGM03]). For certain classes of algebraic Riccati equations (say, CARE, DARE, NARE associated with M-matrices, etc.), there are specific results on the conditioning (see, for instance, [BK06, GH07, XXL12]).
14. Numerical solution of algebraic Riccati equations
    (a) A classical algorithm for solving algebraic Riccati equations consists of computing suitable invariant (or deflating) subspaces, say by means of the Schur method. For solving CARE, there are specific methods tailored for the Hamiltonian structure of the matrix H of Eq. (19.16), which include the Hamiltonian QR algorithm, the URV algorithms, and the multishift algorithm. Another classical algorithm is Newton's method, which requires the solution of a Lyapunov equation at each step.

    (b) Recently, much literature has been published on doubling methods, including the structure-preserving doubling algorithm and the cyclic reduction algorithm. These algorithms have quadratic convergence and a lower computational cost per step, with respect to Newton's method.

    (c) The case of large-scale problems, where the matrix coefficients of the Riccati equations have some rank structure or are sparse matrices, deserves special attention. In fact, the large size of the coefficients makes useless general solution algorithms. The most used numerical method is Newton's method, whose step requires the solution of a linear equation with large and sparse coefficients. For the latter problem, specific algorithms can be used (see Section 19.2). The literature on this topic is continuously evolving.

We refer the reader to [BIM12] for a recent overview of numerical methods.

Examples:

The following examples are from [BIM12].

1. The nonsymmetric algebraic Riccati equation defined by the coefficients

$$A=\begin{bmatrix}3&0\\2&3\end{bmatrix},\quad B=\begin{bmatrix}-1&1\\1&1\end{bmatrix},\quad C=\begin{bmatrix}-2&0\\-2&0\end{bmatrix},\quad D=\begin{bmatrix}-2&1\\-1&0\end{bmatrix},$$

   has solutions

$$X_1=\begin{bmatrix}1&1\\1&1\end{bmatrix},\quad X_2=\begin{bmatrix}0&1\\1&0\end{bmatrix}.$$

   Moreover,

$$H\begin{bmatrix}I\\X_1\end{bmatrix}=\begin{bmatrix}I\\X_1\end{bmatrix}U_1,\quad U_1=A-BX_1=\begin{bmatrix}3&0\\0&1\end{bmatrix},$$
$$H\begin{bmatrix}I\\X_2\end{bmatrix}=\begin{bmatrix}I\\X_2\end{bmatrix}U_2,\quad U_2=A-BX_2=\begin{bmatrix}2&1\\1&2\end{bmatrix},$$

   where H is defined in Eq. (19.14) and the matrices U_1, U_2 have the same eigenvalues.

2. Consider the equation $-X^2+6X-4E=0$, where $E=\begin{bmatrix}1&1\\1&1\end{bmatrix}$, which can be associated with the singular irreducible M-matrix

$$M=\begin{bmatrix}2&0&-1&0\\0&2&0&-1\\-4&-4&4&0\\-4&-4&0&4\end{bmatrix}.$$

   The NARE has four solutions, two of which are positive

$$X_1=E,\quad X_2=2E,\quad X_3=\begin{bmatrix}5&-1\\-1&5\end{bmatrix},\quad X_4=\begin{bmatrix}4&-2\\-2&4\end{bmatrix};$$

   moreover, $X_{\min}=X_1$.

3. The matrices

$$A=-\begin{bmatrix}1&1\\3&0\end{bmatrix},\quad B=\begin{bmatrix}2&1\\1&2\end{bmatrix},\quad C=\begin{bmatrix}0&-3\\-3&2\end{bmatrix},$$

   are the coefficients of a CARE such that $B\succeq 0$ and both (A,B) and $(-A,B)$ are stabilizable. Thus, by Facts 7, 8, and 9, the CARE defined by these coefficients has solutions X_+, X_- and any Hermitian solution X is such that $X_-\preceq X\preceq X_+$.
   The CARE has six solutions, four of which are Hermitian, and precisely

$$X_1=\begin{bmatrix}-1&0\\0&-1\end{bmatrix},\quad X_2=\begin{bmatrix}0&0\\0&-1\end{bmatrix},\quad X_3=\frac{1}{3}\begin{bmatrix}5&-4\\-4&-1\end{bmatrix},\quad X_4=\begin{bmatrix}2&-2\\-2&1\end{bmatrix};$$

   moreover, $X_+=X_4$, $X_-=X_1$, $X_-\preceq X_2\preceq X_+$ and $X_-\preceq X_3\preceq X_+$, while there is not an ordering relation between X_2 and X_3.

20.1 Algebraic Properties 20-1
20.2 Analytic Properties 20-6
20.3 Residual and Perturbation Bounds 20-9
References.. 20-16

An *invariant subspace* is a generalization of the space spanned by an eigenvector of a matrix. Specifically, an invariant subspace $\mathcal{X}$ of a matrix A is a subspace that is mapped by A into itself. If the columns of X form a basis for $\mathcal{X}$, then there is a unique matrix L, called the *Rayleigh quotient,* such that $AX = XL$—which corresponds to the equation $A\mathbf{x} = \lambda\mathbf{x}$ defining an eigenvector and its eigenvalue.

There are good reasons, both theoretical and practical, for working with invariant subspaces. For example, the theoretically important Jordan canonical form can be regarded as a decomposition of A into invariant subspaces in which the corresponding Rayleigh quotients are its Jordan blocks. Practically, the decomposition of a matrix into invariant subspaces can reduce the work in solving a problem to that of solving the same problems for the individual (perhaps much smaller) Rayleigh quotients. Finally, matrices with nearly equal eigenvalues give rise to both theoretical and computational difficulties. Collecting well-separated clusters of eigenvalues in separate Rayleigh quotients enables one to tackle the difficulties piecewise.

The theory of invariant subspaces has three aspects: the algebraic theory, the analytic theory, and the general perturbation theory. The first aspect has been exhaustively treated in [GLR06]. Section 20.1 reviews the basics. The analytic theory uses complex analysis to derive properties of invariant subspaces. Topics include the integral representation of spectral projectors, matrix functions on invariant subspaces, and series expansions for eigensystems of matrices whose elements are holomorphic functions of a complex variable. These topics are treated in Section 20.2. Perturbation theory investigates the behavior an invariant subspace when A is perturbed by the addition of a matrix E. Closely related are residual bounds for approximate invariant subspaces. Both topics will be treated in Section 20.3.

Invariant subspaces are sometimes called eigenspaces. Bear in mind, however, that the term eigenspace is used in two ways in the literature. In addition to meaning an invariant subspace, it can also mean the space of eigenvectors corresponding to an eigenvalue, which is the sense in which it is used in this handbook.

Throughout this chapter, A will be a matrix of order n with complex elements (written $A \in \mathbb{C}^{n\times n}$). The conjugate transpose of A will be written A^*.

20.1 Algebraic Properties

This section will treat the basic algebraic properties of invariant subspaces. Facts 20.1.1–20.1.6 describe the relations between bases for invariant subspaces and their Rayleigh quotients. Facts 20.1.7 and 20.1.8 show how invariant subspaces can be used to reduce a matrix to block triangular form and further, under certain conditions, to block diagonal form. These forms, though not canonical, frequently suggest simple proofs of theorems that would be more difficult to prove using less direct techniques based on projectors. Fact 20.1.9 shows that general block diagonalization is equivalent to a representation by spectral projectors. Fact 20.1.10 presents a widely used decomposition that is closely related to the Jordan canonical form. The section concludes with a result on spectral representations and the evaluation of matrix functions.

Throughout this section, (L, X) will be an eigenpair of A and $\mathcal{X} = \operatorname{range} X$ will be the corresponding invariant subspace. (For definitions of these terms see below.)

Definitions:

A subspace $\mathcal{X} \subseteq \mathbb{C}^n$ is an **invariant subspace** of A if $\mathbf{x} \in \mathcal{X} \implies A\mathbf{x} \in \mathcal{X}$, or equivalently if $A\mathcal{X} \subseteq \mathcal{X}$.

If X is a **basis** for $\mathcal{X}$ — that is, if the columns of X are independent and span $\mathcal{X}$ — then there is a unique matrix L such that

$$AX = XL.$$

The matrix L is the **Rayleigh quotient** of the **eigenbasis** X. The pair (L, X) is an **eigenpair** of A. The eigenvalues of L, counting multiplicities, are the **eigenvalues of the invariant subspace** $\mathcal{X}$.

A subspace $\mathcal{Y}$ is a **left invariant subspace** of A if it is an invariant subspace of A^*. If Y is a basis for $\mathcal{Y}$ and $Y^*A = LY^*$, then (L, Y^*) is a **left eigenpair** of A.

The eigenpairs (L, X) and (M, U) are **complementary** if their invariant subspaces $\mathcal{X}$ and $\mathcal{U}$ satisfy $\mathbb{C}^n = \mathcal{X} \oplus \mathcal{U}$.

Let λ be an eigenvalue of A. The **root invariant subspace** of λ, written $\mathcal{R}_\lambda(A)$, is the space spanned by the columns of the Jordan basis of A corresponding to the Jordan blocks containing λ (see Section 6.2). This space may be written $\mathcal{R}_\lambda$ when A is known from context. (Root subspaces are also called generalized eigenspaces.)

An invariant subspace $\mathcal{X}$ is **simple** if it is the direct (also the setwise) sum of root subspaces. If (X, L) is an eigenpair for a simple invariant subspace $\mathcal{X}$, then (X, L) is a **simple eigenpair**.

A matrix P of order n is called a **spectral projector** of A if $P^2 = P$ and $PA = AP$.

A **spectral representation** of A is a decomposition of the form

$$A = P_1A_1P_1 + P_2AP_2 + \cdots + P_mAP_m,$$

where the P_i are spectral projectors of A and $P_iP_j = 0$ for $i \neq j$. (For an alternative form see Fact 20.1.9.)

Two subspaces $\mathcal{X}$ and $\mathcal{Y}$ of equal dimension are **oblique** if for any bases X and Y for $\mathcal{X}$ and $\mathcal{Y}$, the matrix Y^*X is nonsingular. If $Y^*X = I$, the bases are **biorthonormal**.

Facts: Most of the material in this section may be found in [SS90, Chap. V.1], [Ste01, Chap. IV.4]. Also see [Cha93], [GLR06], and [Kat66, Chap. 1]

1. The pair (M, W) is an eigenpair of L if and only if (M, XW) is an eigenpair of A. In particular, $(\mu, \mathbf{w})$ is an eigenpair of L if and only if $(\mu, X\mathbf{w})$ is an eigenpair of A.
2. If S is nonsingular, then $(S^{-1}X, L)$ is an eigenpair of $S^{-1}AS$. If T is nonsingular, then $(XT, T^{-1}LT)$ is an eigenpair of A.
3. If $\mathbf{w}_0, \mathbf{w}_1, \ldots, \mathbf{w}_m$ is a Jordan chain for L corresponding to the eigenvalue λ (see Section 6.2), then the vectors Xw_i form a Jordan chain for A corresponding to λ.
4. If $\mathcal{X}$ is a simple eigenspace of dimension one, then its eigenvalue is a simple eigenvalue of A. More generally, the notion of simplicity embodies the separation of eigenvalues in the complex plane. Just as a simple eigenvalue of A is separated from the other

eigenvalues of A counting multiplicity, so are the eigenvalues of a simple invariant subspace separated from the remaining eigenvalues.

5. [Ste01, p. 246] If $\mathcal{L}$ is a multiset of eigenvalues of A such that the number of each distinct eigenvalue is equal to its algebraic multiplicity, then there are unique left and right invariant subspaces with the same multiset of eigenvalues.
6. If X^{I} is a left inverse of X, that is if $X^{\mathrm{I}}X = I$, then $L = X^{\mathrm{I}}AX$. In particular:
   (a) If $X^{\dagger} = (X^*X)^{-1}X^*$ is the pseudo-inverse (also known as the Moore Penrose generalized inverse) of X, then $L = X^{\dagger}AX$.
   (b) If X is orthonormal, then $L = X^*AX$.
   (c) If $(\lambda, \mathbf{x})$ is an eigenpair, then $\lambda = \frac{\mathbf{x}^*A\mathbf{x}}{\mathbf{x}^*\mathbf{x}}$ (which shows where the "quotient" in "Rayleigh quotient" comes from).
7. (*Block triangularization and consequences*) Let $\mathcal{X}_1 = \mathcal{X}$ and $X_1 = X$ (for consistency with Fact 8) and let U be chosen so that $[X_1\ U]$ is nonsingular and let $\begin{bmatrix} V^* \\ Y_2^* \end{bmatrix} = [X\ U]^{-1}$. Then

$$\begin{bmatrix} V^* \\ Y_2^* \end{bmatrix} A[X_1\ U] = \begin{bmatrix} L_1 & H \\ 0 & L_2 \end{bmatrix}. \tag{20.1}$$

   In particular:
   (a) The orthogonal complement of $\mathcal{X}_1$ is a left invariant subspace of A.
   (b) The eigenvalues of L_1, counting multiplicities, are eigenvalues of A.
8. (*Block diagonalization and consequences*)
   If, in the notation of the Fact 20.1.7, the Sylvester equation

$$L_1Q - QL_2 = -H \tag{20.2}$$

   has a solution (note that other forms of the Sylvester equation appear in the literature; e.g., $L_1Q + QL_2$), then

$$\begin{bmatrix} I & -Q \\ 0 & I \end{bmatrix} \begin{bmatrix} L_1 & H \\ 0 & L_2 \end{bmatrix} \begin{bmatrix} I & Q \\ 0 & I \end{bmatrix} = \begin{bmatrix} L_1 & 0 \\ 0 & L_2 \end{bmatrix}.$$

   In particular:
   (a) From Eq. (20.1)

$$\begin{bmatrix} V^* - QY_2^* \\ Y_2 \end{bmatrix} A[X_1\ \ X_1 + UQ] = \begin{bmatrix} L_1 & 0 \\ 0 & L_2 \end{bmatrix}$$

   Hence, with $X_2 = X_1 + UQ$ and $Y_1^* = V^* - QY_2^*$, (L_1, X_1) and (L_2, X_2) are complementary right eigenpairs and (L_1, Y_1^*) and (L_2, Y_2^*) are complementary left eigenpairs.
   (b) Since Eq. (20.2) has a unique solution if (L_1, X_1) is simple (Fact 20.2.2), any simple invariant subspace a has unique complementary invariant subspace as well as corresponding left invariant subspace.
9. (*Block diagonalization and spectral representations*) Let (L_i, X_i), $i = 1, \ldots, m$, be eigenpairs of A, and suppose that

$$\bigoplus_{i=1}^{m} \operatorname{range}(X_i) = \mathbb{C}^n.$$

Then $X = [X_1 \ \cdots X_m]$ is nonsingular, and the following statements are true.

(a)

$$X^{-1}AX = \operatorname{diag}(L_1, \dots, L_m).$$

(b) If $Y^* = X^{-1} = [Y_1 \cdots Y_n]^*$, where the partitioning is conformal with that of X, then (L_i, Y_i^*) $(i = 1, \dots, m)$ are left eigenpairs of A.

(c) A has a *spectral representation* of the form

$$A = X_1 L_1 Y_1^* + X_2 L_2 Y_2^* + \cdots + X_m L_m Y_m^*. \tag{20.3}$$

(d) If $P_i = X_i Y_i^*$, then the P_i are spectral projectors with $P_i P_j = 0$ for $i \neq j$ and the spectral representation becomes.

$$A = P_1 A P_1 + P_2 A P_2 + \cdots + P_m A P_m$$

10. (*The spectral decomposition*) [Kat66, pp. 40–43], [Cha93, Chap. 1.7]
Let λ_i $(i = 1, \dots, \ell)$ be the distinct eigenvalues of A, λ_i having algebraic multiplicity m_i. Then there are projectors $P_i = X_i Y_i^*$, integers n_i, and matrices D_i satisfying

    1. $D_i^{n_i} = 0$,
    2. $D_i P_i = P_i D_i$,
    3. $D_i P_j = P_j D_i = 0, \quad i \neq j$,

such that

$$A = \sum_{i=1}^{\ell} (\lambda_i P_i + D_i). \tag{20.4}$$

The projectors P_i and the integers n_i are unique, but not the D_i. This representation of A is called the *spectral decomposition* of A.

11. [GLR06, Chap. 2.10] Let f be a scalar function for which the matrix $f(A)$ is defined (see Chapter 17). Then any invariant subspace of A is an invariant subspace of $f(A)$. Moreover, if A has the spectral representation (20.3), then

$$f(A) = X_1 f(L_1) Y_1^* + X_2 f(L_2) Y_2^* + \cdots + X_m f(L_m) Y_m^*.$$

is a spectral representation of $f(A)$.

Examples:

1. A simple invariant subspace has a spectral projector of the form $P = XY^*$, where X and Y are biorthonormal bases for the left and right invariant subspaces. In particular, the root subspaces corresponding to each eigenvalue have spectral projectors.
2. If A has distinct eigenvalues, then A has n eigenpairs $(\lambda_1, \mathbf{x}_1), \dots, (\lambda_n, \mathbf{x}_n)$ where the $\mathbf{x}_i$ are linearly independent and unique up to scaling. If $X = [\mathbf{x}_1 \ \cdots \ \mathbf{x}_n]$ and $Y^* = X^{-1}$, then the columns $\mathbf{y}_i$ are left eigenvectors $\mathbf{y}_1, \dots, \mathbf{y}_n$ satisfying $\mathbf{y}_i^* \mathbf{x}_i = 1$ and $\mathbf{y}_i^* \mathbf{x}_j = 0$ $(i = 1, \dots, n)$. The pairs $(\lambda_i, \mathbf{x}_i)$ and $(\lambda_i, \mathbf{y}_i^*)$ are right and left eigenpairs of A. The spectral projectors are $P_i = \mathbf{x}_i \mathbf{y}_i^*$, and the two forms of the spectral representation are

$$A = \mathbf{x}_1 \lambda_1 \mathbf{y}_1^* + \cdots + \mathbf{x}_n \lambda_n \mathbf{y}_n^* = \lambda_1 P_1 + \cdots + \lambda_n P_n.$$

3. If all the eigenvalues of A are semisimple, then a variant of the construction in Example 20.1.2 works. Specifically, given an eigenvalue, say λ_1 of multiplicity m_1, one may choose

$\mathbf{x}_1, \ldots, \mathbf{x}_{m_1}$ to be independent eigenvectors with common eigenvalue λ_1. This choice is not unique when $m_1 > 1$.

However, this representation is unstable under arbitrarily small perturbations of A. For such perturbations can cause a multiple eigenvalue to split into simple eigenvalues each having its own left and right eigenvectors, and these eigenvectors need not be near the $\mathbf{x}_i$ and $\mathbf{y}_i$ chosen for the construction. The cure for this problem is to cluster the equal semisimple eigenvalues together by setting $L_1 = \operatorname{diag}(\lambda_1, \ldots, \lambda_1)$, etc. and writing the spectral representation in the form

$$A = X_1 L_1 Y_1^* + \cdots + X_\ell L_\ell Y_\ell^*,$$

where ℓ is the number of distinct semisimple eigenvalues. For example, the matrix $A = \operatorname{diag}(2, 2, 3)$ may be written

$$A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix} \begin{bmatrix} 1 & -1 & 0 \\ 0 & 1 & 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \begin{bmatrix} 3 \end{bmatrix} \begin{bmatrix} 0 & 0 & 1 \end{bmatrix}.$$

It can be shown that when A is perturbed to give a nearby matrix $\tilde{A}$, then there are nearby matrices $\tilde{X}_i$, $\tilde{Y}_i$, and $\tilde{L}_i$ corresponding to the original matrices X_i, Y_i, and L_i such that

$$\tilde{A} = \tilde{X}_1 \tilde{L}_1 \tilde{Y}_1^* + \cdots + \tilde{X}_\ell \tilde{L}_\ell \tilde{Y}_\ell^*.$$

True, the $\tilde{L}_i$ may no longer be diagonal and the columns of $\tilde{X}_i$ and $\tilde{Y}_i$ may no longer be eigenvectors, but the $(\tilde{L}_i, \tilde{X}_i)$ are still eigenpairs of $\tilde{A}$ as are the $(\tilde{L}_i, \tilde{Y}_i^*)$.

4. Invariant subspaces can be used to simplify manipulations of complex eigenpairs of real matrices. If A is real and $(\lambda = \alpha + i\beta, \mathbf{x} = \mathbf{u} + i\mathbf{v})$ is a complex eigenpair, then the complex conjugates $\bar{\lambda}$ and $\bar{\mathbf{x}}$ also form an eigenpair. The representation of the two pairs as complex entities requires storing four real vectors in a computer. We can reduce the storage by a factor of two by working with the real eigenpair

$$\left(\begin{bmatrix} \alpha & \beta \\ -\beta & \alpha \end{bmatrix}, [\mathbf{u}\ \mathbf{v}] \right),$$

which contains all the information required to recover both eigenvectors and eigenvalues. Moreover, the cost of computing in real arithmetic is less than the cost for complex arithmetic.

5. An important example of block triangularization is the useful **Schur form** of a matrix [GVL89, Theorem 7.1.3]. Specifically, there is a unitary matrix X such that $T = X^*AX$ is upper triangular. The eigenvalues of A can be made to appear in any order on the diagonal of T. If A is real, the ideas in Example 20.1.4 can be applied to produce a **real Schur form** [GVL89, Theorem 7.4.1] in which X is orthogonal and the diagonal of T consists of 1×1 blocks containing the real eigenvalues of A and 2×2 blocks containing complex conjugate eigenvalues.

6. Invariant subspaces need not, strictly speaking, be invariant. Consider, for example, the Jordan block

$$J_2(0) = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}.$$

The vector $\mathbf{e}_1 = [1\ 0]^*$ is an eigenbasis of $J_2(0)$ with Rayleigh quotient 0. But $J_2(0)\mathbf{e}_1 = 0$, so that the dimension of the invariant subspace is decreased by one. In general, an invariant subspace is truly invariant if and only if its Rayleigh quotients have no zero eigenvalues.

7. An invariant subspace cannot appear in a spectral representation unless it has a complementary subspace that is also an invariant subspace. Such a complement need not exist. Consider, for example, $J_2(0)$. The vector $\mathbf{e}_1$ spans an invariant subspace of dimension one. However, no independent vector $\mathbf{w} = [a\ b]^*$ can also span an invariant subspace. For if $\mathbf{w}$ is independent of $\mathbf{e}_1$, then b must be nonzero, and $J_2(0)\mathbf{w} = b\mathbf{e}_1$, which is independent of $\mathbf{w}$.

8. The spectral decomposition is closely related to the more general Jordan decomposition. To see this, write $J_i(\lambda) = \lambda I_k + K_i$, where K_i is a zero matrix of order i except for ones along its first superdiagonal. Now, to consider a specific example, suppose A has been written in terms of its Jordan form as

$$\begin{aligned} A &= XJX^{-1} \\ &= [X_1\ X_2\ X_3]\mathrm{diag}[J_2(\lambda_1), J_3(\lambda_1), J_2(\lambda_2)][Y_1\ Y_2\ Y_3]^* \\ &= [X_1\ X_2][\mathrm{diag}(\lambda_1 I_2, \lambda_1 I_3) + \mathrm{diag}(K_2, K_3)][Y_1\ Y_2]^* + X_3(\lambda_2 I_2 + K_2)Y_3^* . \\ &\equiv (\lambda_1 P_{\lambda_1} + D_{\lambda_1}) + (\lambda_2 P_{\lambda_2} + D_{\lambda_2}). \end{aligned}$$

It is easily verified that P_{λ_1} and P_{λ_2} are spectral projectors and that $D_{\lambda_1}^3 = 0$ and $D_{\lambda_2}^2 = 0$. From this it is seen that the spectral decomposition amalgamates all the Jordan blocks corresponding to a single eigenvalue into a single structure that only reveals the size of the largest Jordan blocks.

20.2 Analytic Properties

There is an extensive theory of eigenvalues and their perturbations in the complex plane. This section will survey the high points of these results as they concern invariant subspaces. Principle references are [Kat66, pp. 40–43], [Cha93, Chap. 1.7]. See also [Tay66, Chap. 5.6].

Definitions:

The **resolvent** of A is the matrix valued function $R_A(z) = (A - zI)^{-1}$, where z is a complex variable.

The set of values z for which $R_A(z)$ is defined is the **resolvent set** of A. Its complement in the complex plane is the **spectrum** of A, written $\sigma(A)$. The members of $\sigma(A)$ are the eigenvalues of A.

Facts:

1. The resolvent $R_A(z)$ is a holomorphic function of z with poles at the spectrum of A.
2. The resolvent has the following series representations.
   (a) If $z_0 \notin \sigma(A)$, then the power series

   $$R_A(z) = \sum_{k=0}^{\infty} (z - z_0)^k R_A^{k+1}(z_0)$$

   converges for all z satisfying $|z - z_0| < \rho[R_A(z_0)]^{-1}$, where $\rho(A)$ is the spectral radius of A.
   (b) The series

   $$R_A(z) = -\sum_{k=0}^{\infty} \frac{A^k}{z^{k+1}}.$$

   converges for all $z > \rho(A)$.
   (c) If A has the spectral decomposition (20.4), then

   $$R_A(z) = -\sum_{k=1}^{\ell} \left(\frac{P_k}{z - \lambda_k} + \sum_{j=1}^{m_k} \frac{D_k^j}{(z - \lambda_k)^{j+1}} \right).$$

3. Cauchy's integral formula generalizes to functions of matrices. Let (X, L) be a simple eigenpair of A with distinct eigenvalues $\lambda_1, \ldots, \lambda_k$. Let Γ be a union of rectifiable Jordan curves that contains the eigenvalues $\lambda_1, \ldots, \lambda_k$ and excludes the remaining eigenvalues (e.g., Γ could be a simple closed curve or the union of small circles each containing one of the eigenvalues). If $f(z)$ is holomorphic on and inside Γ and P_X is the spectral projector corresponding to the eigenpair (X, L), then
$$P_X f(A) P_X = -\frac{1}{2\pi i}\int_\Gamma f(z) R_A(z)\, dz,$$
where the integral is taken counterclockwise around each Jordan curve. In particular, for $f(z) = 1$, we have
$$P_X = -\frac{1}{2\pi i}\int_\Gamma R_A(z)\, dz, \tag{20.5}$$
and for $f(z) = z$ we have
$$P_X A P_X = -\frac{1}{2\pi i}\int_\Gamma z R_A(z)\, dz.$$
It follows that if $\{\lambda_1, \ldots, \lambda_k\} = \sigma(A)$, then
$$I = -\frac{1}{2\pi i}\int_\Gamma R_A(z)\, dz,$$
and
$$A = -\frac{1}{2\pi i}\int_\Gamma z R_A(z)\, dz. \tag{20.6}$$
4. (*Formulas for derivatives*) Let the condition of the preceding fact hold, and let $f^{(n)}(z)$ be the nth derivative of $f(z)$. Then
$$P_X f^{(n)}(A) P_X = (-1)^{n+1}\frac{n!}{2\pi i}\int_\Gamma f(z) R_A(z)^{-n+1}\, dz.$$
[Caution: $f^{(n)}(A)$ is *not* the nth Frechet derivative of $f(A)$ with respect to A.]
5. [Ste12] Let the elements of $A(z)$ be holomorphic in a region $\mathcal{R}$ containing z_0. Let (X_0, L_0) be a simple eigenpair of $A(z_0)$ with $X_0^* X_0 = I$ and $L_0 = X_0^* A(z_0) X_0$ and let Y_0 be an orthonormal basis for the orthogonal complement of range X. Then there is an open disk $\mathcal{E} = \{z\colon |z - z_0|\} < \epsilon$ and a holomorphic function $Q(z)$ on $\mathcal{E}$ such that if
$$X(z) = [X_0 + Y_0 Q(z)][I + Q(z)^* Q(z)]^{-\frac{1}{2}} \quad \text{and} \quad L(z) = X(z)^* A(z) X(z),$$
then
   (a) $X(z)$ is orthonormal,
   (b) $[X(z_0), L(z_0)] = (X_0, L_0)$,
   (c) $[X(z), L(z)]$ is a simple eigenpair of $A(z)$.
6. [Ste12] In the notation of the previous fact, let
$$Q(z) = Q_1(z - z_0) + Q_2(z - z_0)^2 + \cdots$$

and let

$$\begin{aligned} L(z) &= X_0^* A(z) X_0 = L_0 + L_1(z - z_0) + L_2(z - z_0)^2 + \cdots, \\ H(z) &= X_0^* A(z) Y_0 = H_0 + H_1(z - z_0) + H_2(z - z_0)^2 + \cdots, \\ G(z) &= Y_0^* A(z) X_0 = \phantom{H_0 +{}} G_1(z - z_0) + G_2(z - z_0)^2 + \cdots, \\ M(z) &= Y_0^* A(z) Y_0 = M_0 + M_1(z - z_0) + M_2(z - z_0)^2 + \cdots. \end{aligned}$$

Then $Q(z)$ satisfies the equation

$$Q(z)L(z) - M(z)Q(z) = G(z) - Q(z)H(z)Q(z),$$

and the coefficients Q_n satisfy the equations

$$Q_n L_0 - M_0 Q_n = G_n - \sum_{\substack{i=1:n-1 \\ j=1:n-1 \\ i+j=n}} Q_i L_j + \sum_{\substack{i=1:n-1 \\ j=1:n-1 \\ i+j=n}} M_i Q_j + \sum_{\substack{i=1:n-1 \\ j=1:n-1 \\ k=0:n-2 \\ i+j+k=n}} Q_i H_k Q_j \quad n = 1, 2, \ldots.$$

Examples:

1. Although the formulas in this section are useful, both in theory and practice, they suffer an important limitation. Specifically, suppose that A has an eigenvalue with, say, two Jordan blocks of orders two and three. Then spectral projectors for each block exist. However, the formula (20.5) can only determine the projector corresponding to the combined blocks. In general, the formulas can only deal with simple invariant subspaces.
2. Let $f(z)$ be holomorphic in a region containing zero and let Γ be a circle in that region containing zero. Let J be a Jordan block of order k with eigenvalue 0. An expression for $f(J)$ in terms of f and its derivatives may be obtained as follows. By Eq. (20.6),

   $$f(J) = -\frac{1}{2\pi i} \int_\Gamma f(z) R_J(z)\, dz.$$

   Since $J^k = 0$, we have

   $$-R_J(z) = (zI - J)^{-1} = z^{-1}I + z^{-2}J + z^{-3}J^2 + \cdots + z^{-k}J^{k-1}$$

   Moreover, by the Cauchy integral theorem

   $$f^{(n)}(0) = \frac{n!}{2\pi i} \int_\Gamma \frac{f(z)}{z^{n+1}}\, dz.$$

   Hence

   $$f(J) = f(0)I + f'(0)J + \frac{1}{2} f''(0)J^2 + \cdots + \frac{1}{(k-1)!} f^{(k-1)}(0)J^{k-1}.$$

   This is a special case of the formula (17.3) in Section 17.1.
3. [Rob80] The matrix sign function of a matrix A having no eigenvalues on the imaginary axis may be defined as follows. Let $\lambda_1, \ldots, \lambda_k$ be the distinct eigenvalues of A and let $A = \sum_{i=1}^k \lambda_i P_i$ be a spectral representation of A. Then $\operatorname{sign}(A) = \sum_{i=1}^k \operatorname{sign}(\lambda_i) P_i$, where $\operatorname{sign}(\lambda_i)$ is 1 if the real part of λ_i is positive and -1 if it is negative. This function is not holomorphic, but Cauchy's formula can be used to help compute it. Let Γ be a rectifiable Jordan curve in the right half-plane containing all the λ_i with positive real parts, and set

   $$\operatorname{sign}_+(A) = \frac{1}{2\pi i} \int_\Gamma (zI - A)^{-1}\, dz.$$

   Then $\operatorname{sign}(A) = 2\operatorname{sign}_+(A) - I$.

4. From Facts 20.2.5 and 20.2.6 it follows that

$$X(z) = X_0 + Y_0Q_1(z - z_0) + O[(z - z_0)^2],$$

where

$$Q_1L_0 - M_0Q_1 = G_1. \tag{20.7}$$

This says that for z near z_0, the sensitivity of the subspace is determined by the size of the solution of the Sylvester equation (20.7). If this equation is ill conditioned, so will be $X(z)$.

20.3 Residual and Perturbation Bounds

This section will treat two closely related problems. The first problem starts with an approximate eigenpair (X, L) of A and asks how close is range X to an invariant subspace of A. The second problem starts with an exact eigenpair (X, L) of A and a perturbation E and asks if there is an invariant subspace of $A + E$ that is near range X.

To solve these problems we must answer two subsidiary questions. First, how does one measure the quality of an approximate invariant subspace? Second, how does one measure difference between range X and a true invariant subspace of A? For the first question, the quality of an approximate invariant subspace will be measured by the norm of the residual $AX - XL$, where X has been suitably normalized. Note that since the concern is only with quality of range X, the matrix L may be chosen to minimize the residual norm (see Fact 20.3.3). For the second question, the distance between subspaces will be measured by certain functions of the canonical angles between the subspaces (see Section 21.1).

The two problems are closely related, as the following observations show. If one regards X as an approximate eigenbasis for of $A + E$, then the residual $(A + E)X - XL = EX$ is small in proportion as E is small. Conversely, if the residual $R = AX - XL$ is small, there is a matrix E that is small in proportion as R is small such that (X, L) is an eigenpair of $A + E$ (Fact 20.3.2). Thus, each problem can be cast in terms of the other.

It is well known that eigenvectors corresponding to poorly separated eigenvalues are ill conditioned. Consequently, one might expect a perturbation bounds for an eigenpair (X, L) to depend inversely on the physical separation of the eigenvalues L from those of the complementary Rayleigh quotient M; i.e., on

$$\min\{|\sigma(L) - \sigma(M)|\}. \tag{20.8}$$

Unfortunately, the physical spectral separation is unsuitable for two reasons. First, it can be very sensitive to perturbations in L and M. Second, even when physical separation is comparatively large, the invariant subspace can still be sensitive to perturbations in the matrix A. Both problems can be solved by introducing an effective spectral separation $\text{sep}(L, M)$, defined below, which will appear in the denominator in the bounds to follow. However, in order to go straight to the bounds themselves, the properties of sep will be treated at the end of the section. For the present, it is sufficient to know that $\text{sep}(L, M)$ is never greater than the physical separation (20.8).

For the most part, the concern will be with simple invariant subspaces. However, certain invariant subspaces that are not simple have a continuity of sorts. This will be treated in Fact 20.3.1.

In this section, all norms will be unitarily invariant (although some facts hold more generally). The spectral norm will be denoted by $\|\cdot\|_2$ and the Frobenius norm will be denoted by $\|\cdot\|_{\mathrm{F}}$. For subspaces $\mathcal{X}$ and $\mathcal{Y}$ of equal dimension ℓ, $\Theta(\mathcal{X}, \mathcal{Y}) = \operatorname{diag}(\theta_1, \ldots, \theta_\ell)$ will denote the diagonal matrix of the canonical angles between $\mathcal{X}$ and $\mathcal{Y}$.

The principal references for this section are [SS90, Chap. V] [Ste73], and [DK70].

Definitions:

Let L be of order ℓ and M be of order m. Then the **Sylvester operator** for L and M is the mapping on $\mathbb{C}^{m\times\ell}$

$$\mathbf{S}_{L,M} = Q \mapsto QL - MQ.$$

The **effective spectral separation** of L and M is

$$\operatorname{sep}(L, M) = \inf_{\substack{Q\in\mathbb{C}^{m\times n}\\ \|Q\|=1}} \|\mathbf{S}_{L,M}Q\|.$$

If $\|\cdot\|$ is the spectral norm or the Frobenius norm, the effective separation will be written $\operatorname{sep}_2(A, B)$ or $\operatorname{sep}_{\mathrm{F}}(A, b)$.

Let $f(X)$ be a mapping of $\mathcal{X} \subset \mathbb{C}^{m\times n}$ to $\mathbb{C}^{k\times\ell}$. If for some $X_0 \in \mathcal{X}$ there is a linear operator $f'(X)$ such that for all sufficiently small E

$$f(X_0 + E) = f(X_0) + f'(X_0)E + o(\|E\|),$$

then f is **Frechet differentiable at** X_0 and $f'(X_0)$ is the **Frechet derivative of** f **at** X_0.

Facts:

1. [GLR06, Theorem 15.2.1] An invariant subspace $\mathcal{X}$ of A is said to be stable if for every $\epsilon > 0$ there exists a $\delta > 0$ such that if $\|E\| \le \delta$, $A + E$ has an invariant subspace $\tilde{\mathcal{X}}$ satisfying $\|\sin\Theta(\mathcal{X}, \tilde{\mathcal{X}})\| < \epsilon$. (Owing to the equivalence of norms on finite dimensional spaces, the norms in the above definition can be arbitrary.) Let $\lambda_1, \ldots, \lambda_k$ be the distinct eigenvalues of A. A subspace $\mathcal{X}$ of A is stable if and only if it can be written in the form

$$\mathcal{X} = \mathcal{X}_1 + \mathcal{X}_2 + \cdots + \mathcal{X}_k,$$

   where

   (a) if λ_j has exactly one eigenvector, then $\mathcal{X}_j$ is any invariant subspace of A in the root subspace $\mathcal{R}_{\lambda_k}$,

   (b) if λ_j has two or more linearly independent eigenvectors, then either $\mathcal{X}_j = \{0\}$ or $\mathcal{X}_j = \mathcal{R}_{\lambda_j}$.

2. [Ste01, Theorem IV.2.6] Let $R = AX - XL$ and $E = -RZ^*$, where $Z^*X = I$. Then $\|E\| \le \|R\|\|Y\|$ and $(A + E)X - XL = 0$. In particular, if X is orthonormal, E can be taken to be $-RX^*$, so that $\|E\| = \|R\|$.
3. [Ste01, Theorem IV.2.6] Let $[X\ Y]$ be unitary. The residual norm $\|AX - XL\|$ is minimized when $L = X^*AX$. In this case, $\|R\| = \|Y^*AX\|$. In particular, range X is an invariant subspace of A if and only if $Y^*AX = 0$.
4. [SS90, Theorem V.2.1] Let $[X\ Y]$ be unitary. Let

$$\begin{aligned} L &= X^*AX, & H &= X^*AY,\\ G &= Y^*AX, & M &= Y^*AY, \end{aligned}$$

   so that if $R = AX - XL$, then $\|R\| = \|G\|$. If

$$\frac{\|G\|\|H\|}{\operatorname{sep}^2(L, M)} < 1/4,$$

then there is a unique matrix Q satisfying

$$\|Q\| < 2\frac{\|G\|}{\operatorname{sep}(L, M)}$$

such that

$$[\hat{X}\ \hat{Y}] = \left[(X + YQ)(I + Q^*Q)^{-\frac{1}{2}} \quad (Y - XQ^*)(I + QQ^*)^{-\frac{1}{2}}\right]$$

is orthonormal and $\hat{\mathcal{X}} = \operatorname{range} \hat{X}$ and $\hat{\mathcal{Y}} = \operatorname{range} \hat{Y}$ are left and right invariant subspaces of A. The corresponding Rayleigh quotients are

$$\hat{L} = (I + Q^*Q)^{\frac{1}{2}}(L + HP)(I + Q^*Q)^{-\frac{1}{2}}$$

and

$$\hat{M} = (I + QQ^*)^{-\frac{1}{2}}(M - PH)(I + QQ^*)^{\frac{1}{2}}.$$

They have disjoint spectra so that $\hat{\mathcal{X}}$ and $\hat{\mathcal{X}}_\perp$ are simple invariant subspaces of A. Moreover,

$$\|\tan \Theta(\mathcal{X}, \hat{\mathcal{X}})\| = \|Q\|.$$

5. [SS90, Theorem V.2.7] Let $[X\ Y]$ be unitary and suppose that $\mathcal{X} = \operatorname{range} X$ is a simple invariant subspace of A, so that $G = Y^*AX = 0$. Let

$$\begin{aligned} L &= X^*AX, & H &= X^*AY, \\ & & M &= Y^*AY. \end{aligned}$$

Let $\tilde{A} = A + E$ and

$$\begin{aligned} E_{\mathrm{L}} &= X^*EX, & E_{\mathrm{H}} &= X^*EY, \\ E_{\mathrm{G}} &= Y^*EX, & E_{\mathrm{M}} &= Y^*EY. \end{aligned}$$

Set

$$\begin{aligned} \tilde{\gamma} &= \|E_{\mathrm{G}}\|, \\ \tilde{\eta} &= \|H\| + \|E_{\mathrm{H}}\|, \\ \tilde{\delta} &= \operatorname{sep}(L, M) - \|E_{\mathrm{L}}\| - \|E_{\mathrm{M}}\|. \end{aligned}$$

If $\tilde{\delta} > 0$ and

$$\frac{\tilde{\gamma}\tilde{\eta}}{\tilde{\delta}^2} < \frac{1}{4},$$

then there is a unique matrix Q satisfying

$$\|Q\| < 2\frac{\tilde{\gamma}}{\tilde{\delta}}$$

such that the matrix

$$[\tilde{X}\ \tilde{Y}] = \left[(X + YQ)(I + Q^*Q)^{-\frac{1}{2}} \quad (Y - XQ^*)(I + QQ^*)^{-\frac{1}{2}}\right]$$

is orthogonal and $\tilde{\mathcal{X}} = \operatorname{range} \tilde{X}$ and $\mathcal{Y} = \operatorname{range} \tilde{Y}$ are simple left and right invariant subspaces of $\tilde{A}$. The Rayleigh quotients for these bases are

$$\tilde{L} = (I + Q^*Q)^{\frac{1}{2}}[L + E_{\mathrm{L}} + (H + E_{\mathrm{H}})Q](I + Q^*Q)^{-\frac{1}{2}}$$

and

$$\tilde{M} = (I + QQ^*)^{-\frac{1}{2}}[M + E_{\mathrm{M}} - P(H + E_{\mathrm{H}})]](I + QQ^*)^{\frac{1}{2}}.$$

Moreover,

$$\|\tan \Theta(\mathcal{X}, \tilde{\mathcal{X}})\| = \|Q\|.$$

6. [Ste12] In the preceding fact, write $Q(E)$ to stress the dependence of Q on E. Then there is a neighborhood $\mathcal{E}$ of zero such that $Q(E)$ has Frechet derivative $Q'(E)$ in $\mathcal{E}$. Moreover,
$$\|Q'(E)\| \leq \frac{\tilde{\delta}^{-1}}{1-4\tilde{\eta}\tilde{\gamma}/\tilde{\delta}^2} \cdot \left(1+2\frac{\tilde{\gamma}}{\tilde{\delta}}\right)^2 .$$
7. [SS90, Theorem V.3.2] Let A be Hermitian and let
$$[X_{\mathrm{L}}\ \ X_{\mathrm{M}}]^* A [X_{\mathrm{L}}\ \ X_{\mathrm{M}}] = \mathrm{diag}(L, M),$$
where $[X_{\mathrm{L}}\ \ X_{\mathrm{M}}]$ is unitary and $X_{\mathrm{L}} \in \mathbb{C}^{n\times k}$. Let $Z \in \mathbb{C}^{n\times k}$ be orthonormal and $N \in \mathbb{C}^{k\times k}$ be Hermitian. Set
$$R = AZ - ZN.$$
If $\delta = \min|\sigma(L) - \sigma(N)|$, then
$$\|\sin\Theta[\mathrm{range}(X_{\mathrm{L}}), \mathrm{range}(Z)]\|_{\mathrm{F}} \leq \frac{\|R\|_{\mathrm{F}}}{\delta}.$$
8. [DK70][SS90, Theorem V.3.6] In the notation of Fact 20.3.7, suppose that
$$\sigma(N) \subset [\alpha, \beta]$$
and that for some $\delta > 0$,
$$\sigma(M) \subset \mathbb{R} \setminus [\alpha - \delta, \beta + \delta].$$
Then for any unitarily invariant norm
$$\|\sin\Theta[\mathrm{range}(X_{\mathrm{L}}), \mathrm{range}(Z)]\| \leq \frac{\|R\|}{\delta}.$$
In particular, if $\|\cdot\|$ is the matrix 2-norm, then $\max\{\theta_i\} \leq \|R\|/\delta$.
9. [DK70][SS90, Theorem V.3.10] In the notation of Facts 20.3.7 and 20.3.8, let
$$N = Z^*AZ$$
and assume that
$$\sigma(N) \subset [\alpha, \beta].$$
If for some $\delta > 0$
$$\sigma(M) \subset (-\infty, \alpha - \delta] \quad \text{or} \quad \sigma(M) \subset [\beta + \delta, \infty),$$
then
$$\|\tan\Theta[\mathrm{range}(X_{\mathrm{L}}), \mathrm{range}(Z)]\| \leq \frac{\|R\|}{\delta}.$$
10. [SS90, Theorem V.3.12] Let A be a Hermitian matrix with eigenvalues $\lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_n$. Let $Z \in \mathbb{C}^{n\times k}$ be orthonormal and set
$$N = Z^*AX$$
and
$$R = AZ - ZN.$$
Let N have eigenvalues $\mu_1 \geq \mu_2 \geq \cdots \geq \mu_k$ and suppose that there is a number $\delta > 0$ such that exactly $n - k$ of the λ_i lie outside the interval $[\nu_k - \delta, \nu_k + \delta]$. Then if
$$\rho = \frac{\|R\|_2}{\delta} < 1,$$

there is an integer j such that$\lambda_j, \ldots, \lambda_{j+k-1}$ belong to $(\nu_k - \delta, \nu_1 + \delta)$ and

$$|\nu_i - \lambda_{j+i-1}| \leq \frac{1}{1-\rho^2} \frac{\|R\|_2^2}{\delta}, \qquad i = 1, \ldots, k.$$

11. [Ste73]. (*Properties of* sep)

    (a) If the Sylvester operator $\mathbf{S}_{L,M}$ is nonsingular, then

    $$\mathrm{sep}(L, M) = \|\mathbf{S}_{L,M}^{-1}\|_{\mathrm{op}}^{-1}.$$

    Here $\|\cdot\|_{\mathrm{op}}$ is the norm on the space of operators on $\mathbb{C}^{m\times n}$ induced by the underlying matrix norm $\|\cdot\|$ on $\mathbb{C}^{m\times n}$.

    (b) The spectral separation is not greater than the minimum distance between the eigenvalues of L and those of M:

    $$\mathrm{sep}(L, M) \leq \min|\sigma(L) - \sigma(M)|.$$

    (c) For any E_{L} and E_{M},

    $$\mathrm{sep}(L, M) + \|E_{\mathrm{L}}\| + \|E_{\mathrm{M}}\| \geq \mathrm{sep}(L + E_{\mathrm{L}}, M + E_{\mathrm{M}}) \geq \mathrm{sep}(L, M) - \|E_{\mathrm{L}}\| - \|E_{\mathrm{M}}\|.$$

    (d) The following statements are true of $\mathrm{sep}_{\mathrm{F}}$.

    i. $\mathrm{sep}_{\mathrm{F}}(L, M) = \mathrm{sep}_{\mathrm{F}}(M, L)$.

    ii. If $L = \mathrm{diag}(L_1, \ldots, L_p)$ and $M = \mathrm{diag}(M_1, \ldots, M_q)$ then,

    $$\mathrm{sep}_{\mathrm{F}}(L, M) = \min\{\mathrm{sep}_{\mathrm{F}}(L_i, M_j) : i = 1, \ldots, p; j = 1, \ldots, q\}.$$

    iii. If L and M are Hermitian, then

    $$\mathrm{sep}_{\mathrm{F}}(L, M) = \min|\sigma(L) - \sigma(M)|.$$

Examples:

1. The term “stable” in Fact 20.3.1 has a reassuring feel that can be misleading. Conisder, for example, the matrix
$$A(\epsilon) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \epsilon & 0 & 0 \end{bmatrix}.$$
When $\epsilon = 0$, this matrix has an eigenvalue of zero of algebraic multiplicity three. But it has only one eigenvector, $\mathbf{e}_1$, so that the corresponding invariant subspace is not simple. For $\epsilon \neq 0$, $A(\epsilon)$ has three eigenvalues corresponding to the three cube roots of ϵ. The eigenvectors are $[1\ \epsilon^{\frac{1}{3}}\ \epsilon^{\frac{2}{3}}]^*$. Thus, although the eigenvalues and the eigenvectors converge as $\epsilon \to 0$, they have a singularity at $\epsilon = 0$. Things get worse as the order n of the example increases. For example, when $n = 16$, a value of ϵ of 10^{-16} — the size of the rounding unit in IEEE double precision — generates an error of order one in the last component of the eigenvector.
2. This example shows that an eigenvector of A can be very sensitive to perturbations in A, even when its eigenvalue is well separated from the other eigenvalues of A. Consider the matrix
$$S_n = \begin{bmatrix} 0 & 0 \\ 0 & M_{n-1} \end{bmatrix},$$
which is illustrated below for $n = 6$:
$$S_6 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -1 & -1 & -1 & -1 \\ 0 & 0 & 1 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & -1 & -1 \\ 0 & 0 & 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$
This matrix has a simple eigenvalue of zero corresponding to the eigenvector $\mathbf{e}_1$. The remaining eigenvalues are one, so that the physical separation of the eigenvalue zero from its neighbors is one. Now consider the matrix
$$\tilde{S}_n = \begin{bmatrix} 0 & 0 \\ \mathbf{g}_{n-1} & M_{n-1} \end{bmatrix},$$
where $\mathbf{g}_{n-1} = -2^{2-n}\mathbf{e}_{n-1}$. The matrix $\tilde{S}_n$ is illustrated below for $n = 6$.
$$\tilde{S}_6 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -1 & -1 & -1 & -1 \\ 0 & 0 & 1 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & -1 & -1 \\ 0 & 0 & 0 & 0 & 1 & -1 \\ -1/16 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$
The matrix $\tilde{S}_n$ still has a simple eigenvalue of zero and the remaining eigenvalues are one. But the eigenvector corresponding to zero is now
$$[1\ 2^{-1}\ 2^{-2}\ \cdots\ 2^{3-n}\ 2^{2-n}\ 2^{2-n}]^* \equiv [1\ \mathbf{p}_{n-1}^*]^*,$$
where $\mathbf{p}_{n-1} = M_{n-1}^{-1}\mathbf{g}_{n-1}$. Hence
$$\|\mathbf{p}_{n-1}\|_2 \leq \|M_{n-1}^{-1}\|_2 \|\mathbf{g}_{n-1}\|_2 = \frac{\|\mathbf{g}_{n-1}\|_2}{\mathrm{sep}_2(0, M_{n-1})}. \tag{20.9}$$

The following display gives the values of sep_2, $\|\mathbf{g}_{n-1}\|_2$ $\|\mathbf{p}_{n-1}\|_2$, and $\|\mathbf{g}_{n-1}\|_2/\mathrm{sep}_2$ for several values of n.

n	sep_2	$\|\mathbf{g}\|_2$	$\|\mathbf{p}\|_2$	$\|\mathbf{g}\|_2/\mathrm{sep}_2$
10	5.86e−03	3.91e−03	5.77e−01	6.67e−01
20	5.72e−06	3.81e−06	5.77e−01	6.67e−01
30	5.59e−09	3.73e−09	5.77e−01	6.67e−01
40	5.46e−12	3.64e−12	5.77e−01	6.67e−01
50	5.34e−15	3.55e−15	5.77e−01	6.66e−01

As n increases, the size of the perturbation $\mathbf{g}_{n-1}$ decreases. Yet for all values of n the perturbation $\mathbf{p}_{n-1}$ is of order one. This is because sep_2 decreases so that the ratio of $\|\mathbf{g}_{n-1}\|$ to sep_2 is effectively constant, in spite of the good separation of the eigenvalues of M_{n-1} from zero. Note that the last two columns are of the same order of magnitude, showing that the right-hand side of Eq. (20.9) is a good predictor of the actual error.

3. In interpreting bounds like $\|\tan\Theta(\mathcal{X},\tilde{\mathcal{X}})\| \leq \|Q\|$ one must take into account the norm. The most commonly used unitarily invariant norms are the Frobenius norm $\|\cdot\|_{\mathrm{F}}$ and the spectral norm $\|\cdot\|_2$. For the Frobenius norm, the inequality may be written

$$\max\{\theta_i\} \leq \sqrt{\sum_i \theta_i^2} = \|\Theta(\mathcal{X},\tilde{\mathcal{X}})\|_{\mathrm{F}} \leq \|\tan\Theta(\mathcal{X},\tilde{\mathcal{X}})\|_{\mathrm{F}} \leq \|Q\|_{\mathrm{F}}.$$

For the spectral norm the inequality becomes

$$\max\{\theta_i\} = \|\Theta(\mathcal{X},\tilde{\mathcal{X}})\|_2 \leq \|\tan\Theta(\mathcal{X},\tilde{\mathcal{X}})\|_2 \leq \|Q\|_2.$$

Thus, Frobenius norm bounds the square root of the sum of squares of the angles, while the spectral norm bounds only the maximum value of the angles. However, this advantage is offset by the fact that $\|Q\|_{\mathrm{F}} \geq \|Q\|_2$.

4. Fact 20.3.5 gives simple first order perturbation bounds for eigenpairs. Specifically, it is easy to see that Q is the solution of the Sylvester equation $QL - MQ = G$,

$$\tilde{X} = X + YQ + O(\|E\|^2)$$

and

$$\tilde{L} = L + E_{\mathrm{L}} + HQ + O(\|E\|^2).$$

Note that if A is Hermitian, then $H = 0$, and

$$\tilde{L} = L + E_{\mathrm{L}} + O(\|E\|^2) = X^*(A+E)X + O(\|E\|^2).$$

This is a generalization of the well-known fact that if $(\lambda, \mathbf{x})$ is a simple eigenpair of a Hermitian matrix A, then the Rayleigh quotient $\mathbf{x}^*(A+E)\mathbf{x}/\mathbf{x}^*\mathbf{x}$ is an $O(\|E\|^2)$ approximation to the eigenvalue of $A + E$ corresponding to λ.

5. When L is of order one, the results in the previous example simplify to the following first order approximations to the perturbed eigenvector and eigenvalue.

$$\tilde{\mathbf{x}} = \mathbf{x} + Y(\lambda I - M)Y^* E\mathbf{x} + O(\|E\|^2)$$

and

$$\tilde{\lambda} = \lambda + \mathbf{x}^* E\mathbf{x} + \mathbf{x}^* AY(\lambda I - M)^{-1} Y^* E\mathbf{x} + O(\|E\|^2).$$

University of Texas at Arlington

There is a vast amount of material in matrix (operator) perturbation theory. Related books that are worth mentioning are [SS90], [Par98], [Bha96], [Bau85], and [Kat70]. In this chapter, we attempt to include the most fundamental results up to date, except those for linear systems and least squares problems for which the reader is referred to Section 51.1 and Section 52.6.

Throughout this chapter, $\|\cdot\|_{\mathrm{UI}}$ denotes a general unitarily invariant norm. Two commonly used ones are the spectral norm $\|\cdot\|_2$ and the Frobenius norm $\|\cdot\|_{\mathrm{F}}$.

21.1 Eigenvalue Problems

The reader is referred to Sections 4.4, 16.1, and 16.2 for more information on eigenvalues and their locations.

Definitions:

Let $A \in \mathbb{C}^{n\times n}$. A scalar–vector pair $(\lambda, \mathbf{x}) \in \mathbb{C} \times \mathbb{C}^n$ is an **eigenpair** of A if $\mathbf{x} \neq 0$ and $A\mathbf{x} = \lambda\mathbf{x}$.

A vector–scalar–vector triplet $(\mathbf{y}, \lambda, \mathbf{x}) \in \mathbb{C}^n \times \mathbb{C} \times \mathbb{C}^n$ is an **eigentriplet** if $\mathbf{x} \neq 0$, $\mathbf{y} \neq 0$, and $A\mathbf{x} = \lambda\mathbf{x}$, $\mathbf{y}^*A = \lambda\mathbf{y}^*$.

For a simple eigenvalue λ, the quantity

$$\mathrm{cond}(\lambda) = \frac{\|\mathbf{x}\|_2\|\mathbf{y}\|_2}{|\mathbf{y}^*\mathbf{x}|}$$

is its **individual condition number**, where $(\mathbf{y}, \lambda, \mathbf{x}) \in \mathbb{C}^n \times \mathbb{C} \times \mathbb{C}^n$ is the associated eigentriplet of A.

Let $\sigma(A) = \{\lambda_1, \lambda_2, \ldots, \lambda_n\}$, the multiset of A's eigenvalues, and set

$$\Lambda = \mathrm{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n), \quad \Lambda_\tau = \mathrm{diag}(\lambda_{\tau(1)}, \lambda_{\tau(2)}, \ldots, \lambda_{\tau(n)}),$$

where τ is a **permutation** of $\{1, 2, \ldots, n\}$. For real diagonal Λ, i.e., all λ_j's are real,

$$\Lambda^{\uparrow} = \operatorname{diag}(\lambda_1^{\uparrow}, \lambda_2^{\uparrow}, \ldots, \lambda_n^{\uparrow}).$$

$\Lambda^{\uparrow}$ is in fact a Λ_τ for which the permutation τ makes $\lambda_{\tau(j)} = \lambda_j^{\uparrow}$ for all j.

Given two square matrices A_1 and A_2, the **separation** $\operatorname{sep}(A_1, A_2)$ between A_1 and A_2 is defined as [SS90, p. 231]

$$\operatorname{sep}(A_1, A_2) = \inf_{\|X\|_2=1} \|XA_1 - A_2X\|_2.$$

A is perturbed to $\widetilde{A} = A + \Delta A$. *The same notation is adopted for* $\widetilde{A}$, *except all symbols with tildes.*

Let $X, Y \in \mathbb{C}^{n\times k}$ with $\operatorname{rank}(X) = \operatorname{rank}(Y) = k$. The **canonical angles** between their column spaces are $\theta_i = \operatorname{arc}\cos\sigma_i$, where $\{\sigma_i\}_{i=1}^k$ are the singular values of $(Y^*Y)^{-1/2}Y^*X(X^*X)^{-1/2}$. Define the **canonical angle matrix** between X and Y as

$$\Theta(X, Y) = \operatorname{diag}(\theta_1, \theta_2, \ldots, \theta_k).$$

For $k = 1$, i.e., $\mathbf{x}, \mathbf{y} \in \mathbb{C}^n$ (both nonzero), we use $\angle(\mathbf{x}, \mathbf{y})$, instead, to denote the canonical angle between the two vectors.

Facts:

1. [SS90, p. 168] (*Elsner*) $\max_i \min_j |\widetilde{\lambda}_i - \lambda_j| \le (\|A\|_2 + \|\widetilde{A}\|_2)^{1-1/n}\|\Delta A\|_2^{1/n}$.
2. [Bha96, p. 229] (*Elsner-Bhatia-Krause*) There exists a permutation τ of $\{1, 2, \ldots, n\}$ such that
$$\|\Lambda - \widetilde{\Lambda}_\tau\|_2 \le 4(\|A\|_2 + \|\widetilde{A}\|_2)^{1-1/n}\|\Delta A\|_2^{1/n}.$$
3. [SS90, p. 183] Let $(\mathbf{y}, \mu, \mathbf{x})$ be an eigentriplet of A, where μ is simple. ΔA changes μ to $\mu + \Delta\mu$ with
$$\Delta\mu = \frac{\mathbf{y}^*(\Delta A)\mathbf{x}}{\mathbf{y}^*\mathbf{x}} + O(\|\Delta A\|_2^2),$$
and $|\Delta\mu| \le \operatorname{cond}(\mu)\|\Delta A\|_2 + O(\|\Delta A\|_2^2)$.
4. [Sun92] Let μ be a semisimple eigenvalue of A with multiplicity k, and let $X, Y \in \mathbb{C}^{n\times k}$ be the associated right and left eigenvector matrix (i.e., $AX = X\mu$ and $Y^*A = \mu Y^*$) such that $Y^*X = I_k$. ΔA changes the k copies of μ to $\mu + \Delta\mu_i$, where $\Delta\mu_i$ $(1 \le i \le k)$ are the eigenvalues of $Y^*(\Delta A)X$ up to $O(\|\Delta A\|_2^2)$.
5. [SS90, p. 205] If A and $A + \Delta A$ are Hermitian, then
$$\|\Lambda^{\uparrow} - \widetilde{\Lambda}^{\uparrow}\|_{\text{UI}} \le \|\Delta A\|_{\text{UI}}.$$
6. [Bha96, p. 165] (*Hoffman–Wielandt*) If A and $A + \Delta A$ are normal, then there exists a permutation τ of $\{1, 2, \ldots, n\}$ such that $\|\Lambda - \widetilde{\Lambda}_\tau\|_{\text{F}} \le \|\Delta A\|_{\text{F}}$.
7. [Sun96] If A is normal, then there exists a permutation τ of $\{1, 2, \ldots, n\}$ such that $\|\Lambda - \widetilde{\Lambda}_\tau\|_{\text{F}} \le \sqrt{n}\|\Delta A\|_{\text{F}}$.
8. [SS90, p. 192] (*Bauer–Fike*) If A is diagonalizable and $A = X\Lambda X^{-1}$ is its eigendecomposition, then
$$\max_i \min_j |\widetilde{\lambda}_i - \lambda_j| \le \|X^{-1}(\Delta A)X\|_p \le \kappa_p(X)\|\Delta A\|_p,$$
where $1 \le p \le \infty$.
9. [BKL97] Suppose both A and $\widetilde{A}$ are diagonalizable and have eigendecompositions $A = X\Lambda X^{-1}$ and $\widetilde{A} = \widetilde{X}\widetilde{\Lambda}\widetilde{X}^{-1}$.

(a) There exists a permutation τ of $\{1, 2, \ldots, n\}$ such that

$\|\Lambda - \widetilde{\Lambda}_\tau\|_{\text{F}} \leq \sqrt{\kappa_2(X)\kappa_2(\widetilde{X})}\, \|\Delta A\|_{\text{F}}$.

(b) $\|\Lambda^\uparrow - \widetilde{\Lambda}^\uparrow\|_{\text{UI}} \leq \sqrt{\kappa_2(X)\kappa_2(\widetilde{X})}\|\Delta A\|_{\text{UI}}$ for real Λ and $\widetilde{\Lambda}$.

10. [KPJ82] Let residuals $\mathbf{r} = A\widetilde{\mathbf{x}} - \widetilde{\mu}\widetilde{\mathbf{x}}$ and $\mathbf{s}^* = \widetilde{\mathbf{y}}^* A - \widetilde{\mu}\widetilde{\mathbf{y}}^*$, where $\|\widetilde{\mathbf{x}}\|_2 = \|\widetilde{\mathbf{y}}\|_2 = 1$, and let $\varepsilon = \max\{\|\mathbf{r}\|_2, \|\mathbf{s}\|_2\}$. The smallest error matrix ΔA in the 2-norm, for which $(\widetilde{\mathbf{y}}, \widetilde{\mu}, \widetilde{\mathbf{x}})$ is an exact eigentriplet of $\widetilde{A} = A + \Delta A$, satisfies $\|\Delta A\|_2 = \varepsilon$, and $|\widetilde{\mu} - \mu| \leq \text{cond}(\widetilde{\mu})\, \varepsilon + O(\varepsilon^2)$ for some $\mu \in \sigma(A)$.

11. [KPJ82], [DK70], [Par98, pp. 73, 244] Suppose A is Hermitian, and let residual $\mathbf{r} = A\widetilde{\mathbf{x}} - \widetilde{\mu}\widetilde{\mathbf{x}}$ and $\|\widetilde{\mathbf{x}}\|_2 = 1$.

    (a) The smallest Hermitian error matrix ΔA (in the 2-norm), for which $(\widetilde{\mu}, \widetilde{\mathbf{x}})$ is an exact eigenpair of $\widetilde{A} = A + \Delta A$, satisfies $\|\Delta A\|_2 = \|\mathbf{r}\|_2$.

    (b) $|\widetilde{\mu} - \mu| \leq \|\mathbf{r}\|_2$ for some eigenvalue μ of A.

    (c) Let μ be the closest eigenvalue in $\sigma(A)$ to $\widetilde{\mu}$ and $\mathbf{x}$ be its associated eigenvector with $\|\mathbf{x}\|_2 = 1$, and let $\eta = \min_{\mu \neq \lambda \in \sigma(A)} |\widetilde{\mu} - \lambda|$. If $\eta > 0$, then

$$|\widetilde{\mu} - \mu| \leq \frac{\|\mathbf{r}\|_2^2}{\eta}, \quad \sin\angle(\widetilde{\mathbf{x}}, \mathbf{x}) \leq \frac{\|\mathbf{r}\|_2}{\eta}.$$

12. Let A be Hermitian, $X \in \mathbb{C}^{n\times k}$ have full column rank, and $M \in \mathbb{C}^{k\times k}$ be Hermitian having eigenvalues $\mu_1 \leq \mu_2 \leq \cdots \leq \mu_k$. Set

$$R = AX - XM.$$

There exist k eigenvalues $\lambda_{i_1} \leq \lambda_{i_2} \leq \cdots \leq \lambda_{i_k}$ of A such that the following inequalities hold. Note that subset $\{\lambda_{i_j}\}_{j=1}^k$ may be different at different occurrences.

(a) [Par98, pp. 253–260], [SS90, Remark 4.16, p. 207] (**Kahan–Cao–Xie–Li**)

$$\max_{1\leq j\leq k} |\mu_j - \lambda_{i_j}| \leq \frac{\|R\|_2}{\sigma_{\min}(X)},$$
$$\sqrt{\sum_{j=1}^k (\mu_j - \lambda_{i_j})^2} \leq \frac{\|R\|_{\text{F}}}{\sigma_{\min}(X)}.$$

(b) [SS90, pp. 254–257], [Sun91] If $X^*X = I$ and $M = X^*AX$, and if all but k of A's eigenvalues differ from every one of M's by at least $\eta > 0$ and $\varepsilon_{\text{F}} = \|R\|_{\text{F}}/\eta < 1$, then

$$\sqrt{\sum_{j=1}^k (\mu_k - \lambda_{i_j})^2} \leq \frac{\|R\|_{\text{F}}^2}{\eta\sqrt{1 - \varepsilon_{\text{F}}^2}}.$$

(c) [SS90, pp. 254–257], [Sun91] If $X^*X = I$ and $M = X^*AX$, and there is a number $\eta > 0$ such that either all but k of A's eigenvalues lie outside the open interval $(\mu_1 - \eta, \mu_k + \eta)$ or all but k of A's eigenvalues lie inside the closed interval $[\mu_\ell + \eta, \mu_{\ell+1} - \eta]$ for some $1 \leq \ell \leq k - 1$, and $\varepsilon = \|R\|_2/\eta < 1$, then

$$\max_{1\leq j\leq k} |\mu_j - \lambda_{i_j}| \leq \frac{\|R\|_2^2}{\eta\sqrt{1 - \varepsilon^2}}.$$

(d) [KA10], [KV91], [Li04] Let $U \in \mathbb{C}^{n\times k}$ whose columns span the eigenspace of A associated with $\lambda_j^{\uparrow}$, $j = 1, 2, \ldots, k$. If $X^*X = I$ and $M = X^*AX$, and $\lambda_k^{\uparrow} < \lambda_{k+1}^{\uparrow}$, then

$$\frac{\sum_{j=1}^{k}(\mu_j - \lambda_j^{\uparrow})}{\lambda_n^{\uparrow} - \lambda_1^{\uparrow}} \le \|\sin\Theta(X, U)\|_{\mathrm{F}}^2 \le \frac{\sum_{j=1}^{k}(\mu_j - \lambda_j^{\uparrow})}{\lambda_{k+1}^{\uparrow} - \lambda_k^{\uparrow}}.$$

13. Let A be Hermitian and have decomposition

$$\begin{bmatrix} X_1^* \\ X_2^* \end{bmatrix} A[X_1\ X_2] = \begin{bmatrix} A_1 & \\ & A_2 \end{bmatrix},$$

where $[X_1\ X_2]$ is unitary and $X_1 \in \mathbb{C}^{n\times k}$. Let $Q \in \mathbb{C}^{n\times k}$ have orthonormal columns and for a $k \times k$ Hermitian matrix M set

$$R = AQ - QM.$$

(a) [BDK89, BDM83, DK70] Let $\eta = \min|\mu - \nu|$ over all $\mu \in \sigma(M)$ and $\nu \in \sigma(A_2)$. If $\eta > 0$, then

$$\|\sin\Theta(X_1, Q)\|_{\mathrm{F}} \le \frac{\|R\|_{\mathrm{F}}}{\eta}, \quad \|\sin\Theta(X_1, Q)\|_{\mathrm{UI}} \le c \cdot \frac{\|R\|_{\mathrm{UI}}}{\eta},$$

where the constant

$$c \le \frac{\pi}{2}\int_0^{\pi} \frac{\sin t}{t}\, dt < 2.91.$$

(b) [DK70] If there are $\eta > 0$ and $\alpha \le \beta$ such that either

$$\sigma(M) \subseteq [\alpha, \beta],\ \sigma(A_2) \subset (-\infty, \alpha - \eta] \cup [\beta + \eta, \infty)$$

or

$$\sigma(M) \subset (-\infty, \alpha - \eta] \cup [\beta + \eta, \infty),\ \sigma(A_2) \subseteq [\alpha, \beta],$$

then $\|\sin\Theta(X_1, Q)\|_{\mathrm{UI}} \le \dfrac{\|R\|_{\mathrm{UI}}}{\eta}$.

14. [LL05] Let

$$A = \begin{bmatrix} M & E^* \\ E & H \end{bmatrix}, \ \widetilde{A} = \begin{bmatrix} M & 0 \\ 0 & H \end{bmatrix}$$

be Hermitian, and set $\eta = \min|\mu - \nu|$ over all $\mu \in \sigma(M)$ and $\nu \in \sigma(H)$. Then

$$\max_{1\le j\le n} |\lambda_j^{\uparrow} - \widetilde{\lambda}_j^{\uparrow}| \le \frac{2\|E\|_2^2}{\eta + \sqrt{\eta^2 + 4\|E\|_2^2}}.$$

15. [SS90, p. 230] Let $[X_1\ Y_2]$ be unitary and $X_1 \in \mathbb{C}^{n\times k}$, and let

$$\begin{bmatrix} X_1^* \\ Y_2^* \end{bmatrix} A[X_1\ Y_2] = \begin{bmatrix} A_1 & G \\ E & A_2 \end{bmatrix}.$$

Assume that $\sigma(A_1)\bigcap\sigma(A_2) = \emptyset$, and set $\eta = \mathrm{sep}(A_1, A_2)$. If $\|G\|_2\|E\|_2 < \eta^2/4$, then there is a unique $W \in \mathbb{C}^{(n-k)\times k}$, satisfying $\|W\|_2 \le 2\|E\|_2/\eta$, such that $[\widetilde{X}_1\ \widetilde{Y}_2]$ is unitary and

$$\begin{bmatrix} \widetilde{X}_1^* \\ \widetilde{Y}_2^* \end{bmatrix} A[\widetilde{X}_1\ \widetilde{Y}_2] = \begin{bmatrix} \widetilde{A}_1 & \widetilde{G} \\ 0 & \widetilde{A}_2 \end{bmatrix},$$

where

$$\begin{aligned}\widetilde{X}_1 &= (X_1 + Y_2 W)(I + W^*W)^{-1/2},\\ \widetilde{Y}_2 &= (Y_2 - X_1 W^*)(I + WW^*)^{-1/2},\\ \widetilde{A}_1 &= (I + W^*W)^{1/2}(A_1 + GW)(I + W^*W)^{-1/2},\\ \widetilde{A}_2 &= (I + WW^*)^{-1/2}(A_2 - WG)(I + WW^*)^{1/2}.\end{aligned}$$

Thus, $\|\tan\Theta(X_1, \widetilde{X}_1)\|_2 < \dfrac{2\|E\|_2}{\eta}$.

Examples:

1. Bounds on $\|\Lambda - \widetilde{\Lambda}_\tau\|_{\mathrm{UI}}$ are, in fact, bounds on $\lambda_j - \lambda_{\tau(j)}$ in disguise, only more convenient and concise. For example, for $\|\cdot\|_{\mathrm{UI}} = \|\cdot\|_2$ (spectral norm), $\|\Lambda - \widetilde{\Lambda}_\tau\|_2 = \max_j |\lambda_j - \lambda_{\tau(j)}|$, and for $\|\cdot\|_{\mathrm{UI}} = \|\cdot\|_{\mathrm{F}}$ (Frobenius norm), $\|\Lambda - \widetilde{\Lambda}_\tau\|_{\mathrm{F}} = \left[\sum_{j=1}^n |\lambda_j - \lambda_{\tau(j)}|^2\right]^{1/2}$.
2. Let A, $\widetilde{A} \in \mathbb{C}^{n\times n}$ as follows, where $\varepsilon > 0$.

$$A = \begin{bmatrix} \mu & 1 & & \\ & \mu & \ddots & \\ & & \ddots & 1 \\ & & & \mu \end{bmatrix}, \quad \widetilde{A} = \begin{bmatrix} \mu & 1 & & \\ & \mu & \ddots & \\ & & \ddots & 1 \\ \varepsilon & & & \mu \end{bmatrix}.$$

It can be seen that $\sigma(A) = \{\mu, \ldots, \mu\}$ (repeated n times) and the characteristic polynomial $\det(tI - \widetilde{A}) = (t - \mu)^n - \varepsilon$, which gives $\sigma(\widetilde{A}) = \{\mu + \varepsilon^{1/n} e^{2ij\pi/n}, 0 \le j \le n-1\}$. Thus, $|\widetilde{\lambda} - \mu| = \varepsilon^{1/n} = \|\Delta A\|_2^{1/n}$. This shows that the fractional power $\|\Delta A\|_2^{1/n}$ in Facts 1 and 2 cannot be removed in general.

3. Consider

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & 0 & 4.001 \end{bmatrix} \quad \text{is perturbed by} \quad \Delta A = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0.001 & 0 & 0 \end{bmatrix}.$$

A's eigenvalues are easily read off, and

$$\lambda_1 = 1,\ \mathbf{x}_1 = [1, 0, 0]^T,\ \mathbf{y}_1 = [0.8285, -0.5523, 0.0920]^T,$$

$$\lambda_2 = 4,\ \mathbf{x}_2 = [0.5547, 0.8321, 0]^T,\ \mathbf{y}_2 = [0, 0.0002, -1.0000]^T,$$

$$\lambda_3 = 4.001,\ \mathbf{x}_3 = [0.5547, 0.8321, 0.0002]^T,\ \mathbf{y}_3 = [0, 0, 1]^T.$$

On the other hand, $\widetilde{A}$'s eigenvalues computed by MATLAB's `eig` are $\widetilde{\lambda}_1 = 1.0001$, $\widetilde{\lambda}_2 = 3.9427$, $\widetilde{\lambda}_3 = 4.0582$. The following table gives $|\widetilde{\lambda}_j - \lambda_j|$ with upper bounds up to the first order by Fact 3.

j	$\mathrm{cond}(\lambda_j)$	$\mathrm{cond}(\lambda_j)\|\Delta A\|_2$	$\|\widetilde{\lambda}_j - \lambda_j\|$
1	1.2070	0.0012	0.0001
2	$6.0 \cdot 10^3$	6.0	0.057
3	$6.0 \cdot 10^3$	6.0	0.057

We see that $\mathrm{cond}(\lambda_j)\|\Delta A\|_2$ gives a fairly good error bound for $j = 1$, but dramatically worse for $j = 2, 3$. There are two reasons for this: One is in the choice of ΔA and the other is that ΔA's order of magnitude is too big for the first order bound $\mathrm{cond}(\lambda_j)\|\Delta A\|_2$ to be effective for $j = 2, 3$. Note that ΔA has the same order of magnitude as the difference between λ_2 and λ_3 and that is too big usually. For better understanding of this first order error bound, the reader may play with this example with $\Delta A = \varepsilon \frac{\mathbf{y}_j \mathbf{x}_j^*}{\|\mathbf{y}_j\|_2 \|\mathbf{x}_j^*\|_2}$ for various tiny parameters ε.

4. Let $\Sigma = \operatorname{diag}(c_1, c_2, \ldots, c_k)$ and $\Gamma = \operatorname{diag}(s_1, s_2, \ldots, s_k)$, where $c_j, s_j \geq 0$ and $c_j^2 + s_j^2 = 1$ for all j. The canonical angles between

$$X = Q \begin{bmatrix} I_k \\ 0 \\ 0 \end{bmatrix} V^*, \quad Y = Q \begin{bmatrix} \Sigma \\ \Gamma \\ 0 \end{bmatrix} U^*$$

are $\theta_j = \arccos c_j$, $j = 1, 2, \ldots, k$, where Q, U, V are unitary. On the other hand, every pair of X, $Y \in \mathbb{C}^{n\times k}$ with $2k \leq n$ and $X^*X = Y^*Y = I_k$, having canonical angles $\arccos c_j$, can be represented this way [SS90, p. 40].

5. Fact 13 is most useful when $\|E\|_2$ is tiny and the computation of A's eigenvalues is then decoupled into two smaller ones. In eigenvalue computations, we often seek unitary $[X_1\ X_2]$ such that

$$\begin{bmatrix} X_1^* \\ X_2^* \end{bmatrix} A[X_1\ X_2] = \begin{bmatrix} M & E^* \\ E & H \end{bmatrix}, \quad \begin{bmatrix} X_1^* \\ X_2^* \end{bmatrix} \widetilde{A}[X_1\ X_2] = \begin{bmatrix} M & 0 \\ 0 & H \end{bmatrix},$$

and $\|E\|_2$ is tiny. Since a unitarily similarity transformation does not alter eigenvalues, Fact 13 still applies.

6. [LL05] Consider the 2×2 Hermitian matrix

$$A = \begin{bmatrix} \alpha & \varepsilon \\ \varepsilon & \beta \end{bmatrix},$$

where $\alpha > \beta$ and $\varepsilon > 0$. It has two eigenvalues

$$\lambda_\pm = \frac{\alpha + \beta \pm \sqrt{(\alpha - \beta)^2 + 4\varepsilon^2}}{2},$$

and

$$0 < \begin{Bmatrix} \lambda_+ - \alpha \\ \beta - \lambda_- \end{Bmatrix} = \frac{2\varepsilon^2}{(\alpha - \beta) + \sqrt{(\alpha - \beta)^2 + 4\varepsilon^2}}.$$

The inequalities in Fact 13 become equalities for the example.

21.2 Singular Value Problems

The reader is referred to Section 5.6, Chapters 24 and 58 for more information on singular value decompositions.

Definitions:

$B \in \mathbb{C}^{m\times n}$ has a (first standard form) SVD $B = U\Sigma V^*$, where $U \in \mathbb{C}^{m\times m}$ and $V \in \mathbb{C}^{n\times n}$ are unitary, and $\Sigma = \operatorname{diag}(\sigma_1, \sigma_2, \ldots) \in \mathbb{R}^{m\times n}$ is leading diagonal (σ_j starts in the top-left corner) with all $\sigma_j \geq 0$.

Let $\operatorname{SV}(B) = \{\sigma_1, \sigma_2, \ldots, \sigma_{\min\{m,n\}}\}$, the set of B's singular values, and $\sigma_1 \geq \sigma_2 \geq \cdots \geq 0$, and let $\operatorname{SV}_{\text{ext}}(B) = \operatorname{SV}(B)$ unless $m > n$ for which $\operatorname{SV}_{\text{ext}}(B) = \operatorname{SV}(B) \bigcup \{0, \ldots, 0\}$ (additional $m - n$ zeros).

A vector–scalar–vector triplet $(\mathbf{u}, \sigma, \mathbf{v}) \in \mathbb{C}^m \times \mathbb{R} \times \mathbb{C}^n$ is a **singular-triplet** if $\mathbf{u} \neq 0$, $\mathbf{v} \neq 0$, $\sigma \geq 0$, and $B\mathbf{v} = \sigma\mathbf{u}$, $B^*\mathbf{u} = \sigma\mathbf{v}$.

B is perturbed to $\widetilde{B} = B + \Delta B$. *The same notation is adopted for* $\widetilde{B}$, *except all symbols with tildes.*

Facts:

1. [SS90, p. 204] (*Mirsky*) $\|\Sigma - \widetilde{\Sigma}\|_{\text{UI}} \leq \|\Delta B\|_{\text{UI}}$.
2. Let residuals $\mathbf{r} = B\widetilde{\mathbf{v}} - \widetilde{\mu}\widetilde{\mathbf{u}}$ and $\mathbf{s} = B^*\widetilde{\mathbf{u}} - \widetilde{\mu}\widetilde{\mathbf{v}}$, and $\|\widetilde{\mathbf{v}}\|_2 = \|\widetilde{\mathbf{u}}\|_2 = 1$.
   (a) [Sun98] The smallest error matrix ΔB (in the 2-norm), for which $(\widetilde{\mathbf{u}}, \widetilde{\mu}, \widetilde{\mathbf{v}})$ is an exact singular-triplet of $\widetilde{B} = B + \Delta B$, satisfies $\|\Delta B\|_2 = \varepsilon$, where $\varepsilon = \max\{\|\mathbf{r}\|_2, \|\mathbf{s}\|_2\}$.

   (b) $|\widetilde{\mu} - \mu| \leq \varepsilon$ for some singular value μ of B.

   (c) Let μ be the closest singular value in $\text{sv}_{\text{ext}}(B)$ to $\widetilde{\mu}$ and $(\mathbf{u}, \sigma, \mathbf{v})$ be the associated singular-triplet with $\|\mathbf{u}\|_2 = \|\mathbf{v}\|_2 = 1$, and let $\eta = \min|\widetilde{\mu} - \sigma|$ over all $\sigma \in \text{sv}_{\text{ext}}(B)$ and $\sigma \neq \mu$. If $\eta > 0$, then $|\widetilde{\mu} - \mu| \leq \varepsilon^2/\eta$, and [SS90, p. 260]

   $$\sqrt{\sin^2 \angle(\widetilde{\mathbf{u}}, \mathbf{u}) + \sin^2 \angle(\widetilde{\mathbf{v}}, \mathbf{v})} \leq \frac{\sqrt{\|\mathbf{r}\|_2^2 + \|\mathbf{s}\|_2^2}}{\eta}.$$

3. [LL05] Let

   $$B = \begin{bmatrix} B_1 & F \\ E & B_2 \end{bmatrix} \in \mathbb{C}^{m\times n}, \quad \widetilde{B} = \begin{bmatrix} B_1 & 0 \\ 0 & B_2 \end{bmatrix},$$

   where $B_1 \in \mathbb{C}^{k\times k}$, and set $\eta = \min|\mu - \nu|$ over all $\mu \in \text{sv}(B_1)$ and $\nu \in \text{sv}_{\text{ext}}(B_2)$, and $\varepsilon = \max\{\|E\|_2, \|F\|_2\}$. Then

   $$\max_j |\sigma_j - \widetilde{\sigma}_j| \leq \frac{2\varepsilon^2}{\eta + \sqrt{\eta^2 + 4\varepsilon^2}}.$$

4. [SS90, pp. 260–268] (*Wedin*) Let B, $\widetilde{B} \in \mathbb{C}^{m\times n}$ $(m \geq n)$ have decompositions

   $$\begin{bmatrix} U_1^* \\ U_2^* \end{bmatrix} B[V_1 \ V_2] = \begin{bmatrix} B_1 & 0 \\ 0 & B_2 \end{bmatrix}, \quad \begin{bmatrix} \widetilde{U}_1^* \\ \widetilde{U}_2^* \end{bmatrix} \widetilde{B}[\widetilde{V}_1 \ \widetilde{V}_2] = \begin{bmatrix} \widetilde{B}_1 & 0 \\ 0 & \widetilde{B}_2 \end{bmatrix},$$

   where $[U_1 \ U_2]$, $[V_1 \ V_2]$, $[\widetilde{U}_1 \ \widetilde{U}_2]$, and $[\widetilde{V}_1 \ \widetilde{V}_2]$ are unitary, and U_1, $\widetilde{U}_1 \in \mathbb{C}^{m\times k}$, V_1, $\widetilde{V}_1 \in \mathbb{C}^{n\times k}$. Set

   $$R = B\widetilde{V}_1 - \widetilde{U}_1\widetilde{B}_1, \quad S = B^*\widetilde{U}_1 - \widetilde{V}_1\widetilde{B}_1.$$

   (a) Let $\eta = \min|\widetilde{\mu} - \nu|$ over all $\widetilde{\mu} \in \text{sv}(\widetilde{B}_1)$ and $\nu \in \text{sv}_{\text{ext}}(B_2)$. If $\eta > 0$, then

   $$\sqrt{\|\sin\Theta(U_1, \widetilde{U}_1)\|_{\text{F}}^2 + \|\sin\Theta(V_1, \widetilde{V}_1)\|_{\text{F}}^2} \leq \frac{\sqrt{\|R\|_{\text{F}}^2 + \|S\|_{\text{F}}^2}}{\eta}.$$

   (b) If there are $\alpha \geq 0$ and $\eta > 0$ such that

   $$\widetilde{\mu} \geq \alpha + \eta \text{ for } \widetilde{\mu} \in \text{sv}(\widetilde{B}_1), \text{ and } \nu \leq \alpha \text{ for } \nu \in \text{sv}_{\text{ext}}(B_2),$$

   then

   $$\max\left\{\|\sin\Theta(U_1, \widetilde{U}_1)\|_{\text{UI}}, \ \|\sin\Theta(V_1, \widetilde{V}_1)\|_{\text{UI}}\right\} \leq \frac{\max\{\|R\|_{\text{UI}}, \ \|S\|_{\text{UI}}\}}{\eta}.$$

Examples:

1. Let
$$B = \begin{bmatrix} 3\cdot 10^{-3} & 1 \\ 2 & 4\cdot 10^{-3} \end{bmatrix}, \; \widetilde{B} = \begin{bmatrix} & 1 \\ 2 & \end{bmatrix} = [\mathbf{e}_2 \; \mathbf{e}_1] \begin{bmatrix} 2 & \\ & 1 \end{bmatrix} \begin{bmatrix} \mathbf{e}_1^T \\ \mathbf{e}_2^T \end{bmatrix}.$$
Then $\sigma_1 = 2.000012$, $\sigma_2 = 0.999988$, and $\widetilde{\sigma}_1 = 2$, $\widetilde{\sigma}_2 = 1$. Fact 1 gives
$$\max_{1\le j\le 2} |\sigma_j - \widetilde{\sigma}_j| \le 4\cdot 10^{-3}, \qquad \sqrt{\sum_{j=1}^{2} |\sigma_j - \widetilde{\sigma}_j|^2} \le 5\cdot 10^{-3}.$$
2. Let B be as in the previous example, and let $\widetilde{\mathbf{v}} = \mathbf{e}_1$, $\widetilde{\mathbf{u}} = \mathbf{e}_2$, $\widetilde{\mu} = 2$. Then $\mathbf{r} = B\widetilde{\mathbf{v}} - \widetilde{\mu}\widetilde{\mathbf{u}} = 3\cdot 10^{-3}\mathbf{e}_1$ and $\mathbf{s} = B^*\widetilde{\mathbf{u}} - \widetilde{\mu}\widetilde{\mathbf{v}} = 4\cdot 10^{-3}\mathbf{e}_2$. Fact 2 applies. Note that, without calculating $\mathrm{SV}(B)$, one may bound η needed for Fact 2(c) from below as follows. Since B has two singular values that are near 1 and $\widetilde{\mu} = 2$, respectively, with errors no bigger than $4\cdot 10^{-3}$, then $\eta \ge 2 - (1 + 4\cdot 10^{-3}) = 1 - 4\cdot 10^{-3}$.
3. Let B and $\widetilde{B}$ be as in Example 1. Fact 3 gives $\max_{1\le j\le 2} |\sigma_j - \widetilde{\sigma}_j| \le 1.6\cdot 10^{-5}$, a much better bound than by Fact 1.
4. Let B and $\widetilde{B}$ be as in Example 1. Note $\widetilde{B}$'s SVD there. Apply Fact 4 with $k = 1$ to give a similar bound as by Fact 2(c).
5. Since unitary transformations do not change singular values, Fact 3 applies to B, $\widetilde{B} \in \mathbb{C}^{m\times n}$ having decompositions
$$\begin{bmatrix} U_1^* \\ U_2^* \end{bmatrix} B[V_1 \; V_2] = \begin{bmatrix} B_1 & F \\ E & B_2 \end{bmatrix}, \; \begin{bmatrix} U_1^* \\ U_2^* \end{bmatrix} \widetilde{B}[V_1 \; V_2] = \begin{bmatrix} B_1 & 0 \\ 0 & B_2 \end{bmatrix},$$
where $[U_1 \; U_2]$ and $[V_1 \; V_2]$ are unitary and $U_1 \in \mathbb{C}^{m\times k}$, $V_1 \in \mathbb{C}^{n\times k}$.

21.3 Polar Decomposition

The reader is referred to Section 24.1 for definition and for more information on polar decompositions.

Definitions:

$B \in \mathbb{F}^{m\times n}$ is perturbed to $\widetilde{B} = B + \Delta B$, and their polar decompositions are
$$B = QH, \quad \widetilde{B} = \widetilde{Q}\widetilde{H} = (Q + \Delta Q)(H + \Delta H),$$
where $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$. ΔB *is restricted to* $\mathbb{F}$ *for* $B \in \mathbb{F}$.

Denote the singular values of B and $\widetilde{B}$ as $\sigma_1 \ge \sigma_2 \ge \cdots$ and $\widetilde{\sigma}_1 \ge \widetilde{\sigma}_2 \ge \cdots$, respectively.

The **condition numbers for the polar factors** in the Frobenius norm are defined as
$$\mathrm{cond}_{\mathbb{F}}(X) = \lim_{\delta\to 0} \sup_{\|\Delta B\|_{\mathrm{F}} \le \delta} \frac{\|\Delta X\|_{\mathrm{F}}}{\delta}, \quad \text{for } X = H \text{ or } Q.$$

B is **multiplicatively perturbed** to $\widetilde{B}$ if $\widetilde{B} = D_{\mathrm{L}}^* B D_{\mathrm{R}}$ for some $D_{\mathrm{L}} \in \mathbb{F}^{m\times m}$ and $D_{\mathrm{R}} \in \mathbb{F}^{n\times n}$.

B is said to be **graded** if it can be scaled as $B = GS$ such that G is "well-behaved" (i.e., $\kappa_2(G)$ is of modest magnitude), where S is a scaling matrix, often diagonal but not required so for the following facts. Interesting cases are when $\kappa_2(G) \ll \kappa_2(B)$.

Facts:

1. [CG00] The condition numbers $\mathrm{cond}_{\mathbb{F}}(Q)$ and $\mathrm{cond}_{\mathbb{F}}(H)$ are tabulated as follows, where $\kappa_2(B) = \sigma_1/\sigma_n$.

		$\mathbb{R}$	$\mathbb{C}$
Factor Q	$m = n$	$2/(\sigma_{n-1} + \sigma_n)$	$1/\sigma_n$
	$m > n$	$1/\sigma_n$	$1/\sigma_n$
Factor H	$m \geq n$	$\dfrac{\sqrt{2(1 + \kappa_2(B)^2)}}{1 + \kappa_2(B)}$	

2. [Kit86] $\|\Delta H\|_{\mathrm{F}} \leq \sqrt{2}\|\Delta B\|_{\mathrm{F}}$.
3. [Li95] If $m = n$ and $\mathrm{rank}(B) = n$, then
$$\|\Delta Q\|_{\mathrm{UI}} \leq \frac{2}{\sigma_n + \widetilde{\sigma}_n}\|\Delta B\|_{\mathrm{UI}}.$$
4. [Li95], [LS02] If $\mathrm{rank}(B) = n$, then
$$\|\Delta Q\|_{\mathrm{UI}} \leq \left(\frac{2}{\sigma_n + \widetilde{\sigma}_n} + \frac{1}{\max\{\sigma_n, \widetilde{\sigma}_n\}}\right)\|\Delta B\|_{\mathrm{UI}},$$
$$\|\Delta Q\|_{\mathrm{F}} \leq \frac{2}{\sigma_n + \widetilde{\sigma}_n}\|\Delta B\|_{\mathrm{F}}.$$
5. [Mat93] If $B \in \mathbb{R}^{n\times n}$, $\mathrm{rank}(B) = n$, and $\|\Delta B\|_2 < \sigma_n$, then
$$\|\Delta Q\|_{\mathrm{UI}} \leq -\frac{2\|\Delta B\|_{\mathrm{UI}}}{|\!|\!|\Delta B|\!|\!|_2}\ln\left(1 - \frac{|\!|\!|\Delta B|\!|\!|_2}{\sigma_n + \sigma_{n-1}}\right),$$
where $|\!|\!|\cdot|\!|\!|_2$ is the *Ky Fan 2-norm*, i.e., the sum of the first two largest singular values. (See Section 24.3.)
6. [LS02] If $B \in \mathbb{R}^{n\times n}$, $\mathrm{rank}(B) = n$, and $\|\Delta B\|_2 < \sigma_n + \widetilde{\sigma}_n$, then
$$\|\Delta Q\|_{\mathrm{F}} \leq \frac{4}{\sigma_{n-1} + \sigma_n + \widetilde{\sigma}_{n-1} + \widetilde{\sigma}_n}\|\Delta B\|_{\mathrm{F}}.$$
7. [Li97] Let B and $\widetilde{B} = D_{\mathrm{L}}^* B D_{\mathrm{R}}$ having full column rank. Then
$$\|\Delta Q\|_{\mathrm{F}} \leq \sqrt{\|I - D_{\mathrm{L}}^{-1}\|_{\mathrm{F}}^2 + \|D_{\mathrm{L}} - I\|_{\mathrm{F}}^2} + \sqrt{\|I - D_{\mathrm{R}}^{-1}\|_{\mathrm{F}}^2 + \|D_{\mathrm{R}} - I\|_{\mathrm{F}}^2}.$$
8. [Li97], [Li05] Let $B = GS$ and $\widetilde{B} = \widetilde{G}S$ and assume that G and B have full column rank. If $\|\Delta G\|_2\|G^\dagger\|_2 < 1$, then
$$\|\Delta Q\|_{\mathrm{F}} \leq \gamma\,\|G^\dagger\|_2\|\Delta G\|_{\mathrm{F}},$$
$$\|(\Delta H)S^{-1}\|_{\mathrm{F}} \leq \left(\gamma\,\|G^\dagger\|_2\|G\|_2 + 1\right)\|\Delta G\|_{\mathrm{F}},$$
where $\gamma = \sqrt{1 + (1 - \|G^\dagger\|_2\|\Delta G\|_2)^{-2}}$.

Examples:

1. Take both B and $\widetilde{B}$ to have orthonormal columns to see that some of the inequalities above on ΔQ are attainable.

2. Let
$$B = \frac{1}{\sqrt{2}}\begin{bmatrix} 2.01 & 502 \\ -1.99 & -498 \end{bmatrix} = \frac{1}{\sqrt{2}}\begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}\begin{bmatrix} 10^{-2} & 2 \\ 2 & 5\cdot 10^{2} \end{bmatrix}$$
and
$$\widetilde{B} = \begin{bmatrix} 1.4213 & 3.5497\cdot 10^{2} \\ -1.4071 & -3.5214\cdot 10^{2} \end{bmatrix}$$
obtained by rounding each entry of B to have five significant decimal digits. $B = QH$ can be read off above and $\widetilde{B} = \widetilde{Q}\widetilde{H}$ can be computed by $\widetilde{Q} = \widetilde{U}\widetilde{V}^*$ and $\widetilde{H} = \widetilde{V}\widetilde{\Sigma}\widetilde{V}^*$, where $\widetilde{B}$'s SVD is $\widetilde{U}\widetilde{\Sigma}\widetilde{V}^*$. One has
$$\mathrm{SV}(B) = \{5.00\cdot 10^{2}, 2.00\cdot 10^{-3}\},\ \mathrm{SV}(\widetilde{B}) = \{5.00\cdot 10^{2}, 2.04\cdot 10^{-3}\}$$
and

$\|\Delta B\|_2$	$\|\Delta B\|_F$	$\|\Delta Q\|_2$	$\|\Delta Q\|_F$	$\|\Delta H\|_2$	$\|\Delta H\|_F$
$3\cdot 10^{-3}$	$3\cdot 10^{-3}$	$2\cdot 10^{-6}$	$3\cdot 10^{-6}$	$2\cdot 10^{-3}$	$2\cdot 10^{-3}$

Fact 2 gives $\|\Delta H\|_F \le 3\cdot 10^{-3}$ and Fact 6 gives $\|\Delta Q\|_F \le 10^{-5}$.

3. [Li97] and [Li05] have examples on the use of inequalities in Facts 7 and 8.

21.4 Generalized Eigenvalue Problems

The reader is referred to Section 56.1 for more information on generalized eigenvalue problems.

Definitions:

Let $A, B \in \mathbb{C}^{m\times n}$.

A **matrix pencil** is a family of matrices $A - \lambda B$, parameterized by a (complex) number λ.

The associated **generalized eigenvalue problem** is to find the nontrivial solutions of the equations
$$A\mathbf{x} = \lambda B\mathbf{x} \quad \text{and/or} \quad \mathbf{y}^*A = \lambda\mathbf{y}^*B,$$
where $\mathbf{x} \in \mathbb{C}^n$, $\mathbf{y} \in \mathbb{C}^m$, and $\lambda \in \mathbb{C}$.

$A - \lambda B$ is **regular** if $m = n$ and $\det(A - \lambda B) \neq 0$ for some $\lambda \in \mathbb{C}$.

In what follows, all pencils in question are assumed regular.

An eigenvalue λ is conveniently represented by a nonzero number pair, so-called a **generalized eigenvalue** $\langle\alpha, \beta\rangle$, interpreted as $\lambda = \alpha/\beta$. $\beta = 0$ corresponds to eigenvalue infinity.

A **generalized eigenpair** of $A - \lambda B$ refers to $(\langle\alpha,\beta\rangle, \mathbf{x})$ such that $\beta A\mathbf{x} = \alpha B\mathbf{x}$, where $\mathbf{x} \neq 0$ and $|\alpha|^2 + |\beta|^2 > 0$. A **generalized eigentriplet** of $A - \lambda B$ refers to $(\mathbf{y}, \langle\alpha,\beta\rangle, \mathbf{x})$ such that $\beta A\mathbf{x} = \alpha B\mathbf{x}$ and $\beta\mathbf{y}^*A = \alpha\mathbf{y}^*B$, where $\mathbf{x} \neq 0$, $\mathbf{y} \neq 0$, and $|\alpha|^2 + |\beta|^2 > 0$.

For a simple generalized eigenvalue $\langle\alpha,\beta\rangle$, the quantity
$$\mathrm{cond}(\langle\alpha,\beta\rangle) = \frac{\|\mathbf{x}\|_2\|\mathbf{y}\|_2}{\sqrt{|\mathbf{y}^*A\mathbf{x}|^2 + |\mathbf{y}^*B\mathbf{x}|^2}}$$
is its **individual condition number**, where $(\mathbf{y}, \langle\alpha,\beta\rangle, \mathbf{x})$ is the associated generalized eigentriplet of $A - \lambda B$.

$A - \lambda B$ is perturbed to $\widetilde{A} - \lambda\widetilde{B} = (A + \Delta A) - \lambda(B + \Delta B)$.

Let $\sigma(A, B) = \{\langle\alpha_1,\beta_1\rangle, \langle\alpha_2,\beta_2\rangle, \ldots, \langle\alpha_n,\beta_n\rangle\}$ be the set of the generalized eigenvalues of $A - \lambda B$, and set $Z = [A,\ B] \in \mathbb{C}^{2n\times n}$.

$A - \lambda B$ is **diagonalizable** if it is equivalent to a diagonal pencil, i.e., there are nonsingular $X, Y \in \mathbb{C}^{n\times n}$ such that $Y^*AX = \Lambda$, $Y^*BX = \Omega$, where $\Lambda = \operatorname{diag}(\alpha_1, \alpha_2, \ldots, \alpha_n)$ and $\Omega = \operatorname{diag}(\beta_1, \beta_2, \ldots, \beta_n)$.

$A - \lambda B$ is a **definite pencil** if both A and B are Hermitian and

$$\gamma(A, B) = \min_{\mathbf{x}\in\mathbb{C}^n, \|\mathbf{x}\|_2=1} |\mathbf{x}^*A\mathbf{x} + i\mathbf{x}^*B\mathbf{x}| > 0.$$

The same notation is adopted for $\widetilde{A} - \lambda\widetilde{B}$, *except all symbols with tildes.*

The **chordal distance** between two nonzero pairs $\langle\alpha, \beta\rangle$ and $\langle\widetilde{\alpha}, \widetilde{\beta}\rangle$ is

$$\chi\big(\langle\alpha, \beta\rangle, \langle\widetilde{\alpha}, \widetilde{\beta}\rangle\big) = \frac{|\widetilde{\beta}\alpha - \widetilde{\alpha}\beta|}{\sqrt{|\alpha|^2 + |\beta|^2}\sqrt{|\widetilde{\alpha}|^2 + |\widetilde{\beta}|^2}}.$$

Facts:

1. [SS90, p. 293] Let $(\mathbf{y}, \langle\alpha, \beta\rangle, \mathbf{x})$ be a generalized eigentriplet of $A - \lambda B$, where $\langle\alpha, \beta\rangle$ is simple. $[\Delta A,\ \Delta B]$ changes $\langle\alpha, \beta\rangle = \langle\mathbf{y}^*A\mathbf{x}, \mathbf{y}^*B\mathbf{x}\rangle$ to
$$\langle\widetilde{\alpha}, \widetilde{\beta}\rangle = \langle\alpha, \beta\rangle + \langle\mathbf{y}^*(\Delta A)\mathbf{x}, \mathbf{y}^*(\Delta B)\mathbf{x}\rangle + O(\varepsilon^2),$$
where $\varepsilon = \|[\Delta A,\ \Delta B]\|_2$, and $\chi\big(\langle\alpha, \beta\rangle, \langle\widetilde{\alpha}, \widetilde{\beta}\rangle\big) \le \operatorname{cond}(\langle\alpha, \beta\rangle)\,\varepsilon + O(\varepsilon^2)$.
2. [SS90, p. 301], [Li88] If $A - \lambda B$ is diagonalizable, then
$$\max_i \min_j \chi\big(\langle\alpha_i, \beta_i\rangle, \langle\widetilde{\alpha}_j, \widetilde{\beta}_j\rangle\big) \le \kappa_2(X)\|\sin\Theta(Z^*, \widetilde{Z}^*)\|_2.$$
3. [Li94, Lemma 3.3] (**Sun**)
$$\|\sin\Theta(Z^*, \widetilde{Z}^*)\|_{\text{UI}} \le \frac{\|Z - \widetilde{Z}\|_{\text{UI}}}{\max\{\sigma_{\min}(Z),\ \sigma_{\min}(\widetilde{Z})\}},$$
where $\sigma_{\min}(Z)$ is Z's smallest singular value.
4. The quantity $\gamma(A, B)$ is the minimum distance of the numerical range $W(A + iB)$ to the origin for definite pencil $A - \lambda B$.
5. [SS90, p. 316] Suppose $A - \lambda B$ is a definite pencil. If $\widetilde{A}$ and $\widetilde{B}$ are Hermitian and $\|[\Delta A,\ \Delta B]\|_2 < \gamma(A, B)$, then $\widetilde{A} - \lambda\widetilde{B}$ is also a definite pencil and there exists a permutation τ of $\{1, 2, \ldots, n\}$ such that
$$\max_{1\le j\le n} \chi\big(\langle\alpha_j, \beta_j\rangle, \langle\widetilde{\alpha}_{\tau(j)}, \widetilde{\beta}_{\tau(j)}\rangle\big) \le \frac{\|[\Delta A,\ \Delta B]\|_2}{\gamma(A, B)}.$$
6. [SS90, p. 318] Definite pencil $A - \lambda B$ is always diagonalizable: $X^*AX = \Lambda$ and $X^*BX = \Omega$, and with real spectra. Facts 7 and 10 apply.
7. [Li03] Suppose $A - \lambda B$ and $\widetilde{A} - \lambda\widetilde{B}$ are diagonalizable with real spectra, i.e.,
$$Y^*AX = \Lambda,\ Y^*BX = \Omega \quad \text{and} \quad \widetilde{Y}^*\widetilde{A}\widetilde{X} = \widetilde{\Lambda},\ \widetilde{Y}^*\widetilde{B}\widetilde{X} = \widetilde{\Omega},$$
and all $\langle\alpha_j, \beta_j\rangle$ and all $\langle\widetilde{\alpha}_j, \widetilde{\beta}_j\rangle$ are real. Then the following statements hold, where
$$\Xi = \operatorname{diag}(\chi(\langle\alpha_1, \beta_1\rangle, \langle\widetilde{\alpha}_{\tau(1)}, \widetilde{\beta}_{\tau(1)}\rangle), \ldots, \chi(\langle\alpha_n, \beta_n\rangle, \langle\widetilde{\alpha}_{\tau(n)}, \widetilde{\beta}_{\tau(n)}\rangle))$$
for some permutation τ of $\{1, 2, \ldots, n\}$ (possibly depending on the norm being used). In all cases, the constant factor $\pi/2$ can be replaced by 1 for the 2-norm and the Frobenius norm.

(a) $\|\Xi\|_{\text{UI}} \leq \frac{\pi}{2}\sqrt{\kappa_2(X)\kappa_2(\widetilde{X})}\|\sin\Theta(Z^*, \widetilde{Z}^*)\|_{\text{UI}}$.

(b) If all $|\alpha_j|^2 + |\beta_j|^2 = |\widetilde{\alpha}_j|^2 + |\widetilde{\beta}_j|^2 = 1$ in their eigendecompositions, then $\|\Xi\|_{\text{UI}} \leq \frac{\pi}{2}\sqrt{\|X\|_2\|Y^*\|_2\|\widetilde{X}\|_2\|\widetilde{Y}^*\|_2}\|[\Delta A,\ \Delta B]\|_{\text{UI}}$.

8. Let residuals $\mathbf{r} = \widetilde{\beta}A\widetilde{\mathbf{x}} - \widetilde{\alpha}B\widetilde{\mathbf{x}}$ and $\mathbf{s}^* = \widetilde{\beta}\widetilde{\mathbf{y}}^*A - \widetilde{\alpha}\widetilde{\mathbf{y}}^*B$, where $\|\widetilde{\mathbf{x}}\|_2 = \|\widetilde{\mathbf{y}}\|_2 = 1$. The smallest error matrix $[\Delta A,\ \Delta B]$ in the 2-norm, for which $(\widetilde{\mathbf{y}}, \langle\widetilde{\alpha}, \widetilde{\beta}\rangle, \widetilde{\mathbf{x}})$ is an exact generalized eigentriplet of $\widetilde{A} - \lambda\widetilde{B}$, satisfies $\|[\Delta A,\ \Delta B]\|_2 = \varepsilon$, where $\varepsilon = \max\{\|\mathbf{r}\|_2, \|\mathbf{s}\|_2\}$, and $\chi\big(\langle\alpha,\beta\rangle, \langle\widetilde{\alpha},\widetilde{\beta}\rangle\big) \leq \text{cond}(\langle\widetilde{\alpha},\widetilde{\beta}\rangle)\,\varepsilon + O(\varepsilon^2)$ for some $\langle\alpha,\beta\rangle \in \sigma(A,B)$.
9. [BDD00, p. 128] Suppose A and B are Hermitian and B is positive definite, and let residual $\mathbf{r} = A\widetilde{\mathbf{x}} - \widetilde{\mu}B\widetilde{\mathbf{x}}$ and $\|\widetilde{\mathbf{x}}\|_2 = 1$.

   (a) For some eigenvalue μ of $A - \lambda B$,

   $$|\widetilde{\mu} - \mu| \leq \frac{\|\mathbf{r}\|_{B^{-1}}}{\|\widetilde{\mathbf{x}}\|_B} \leq \|B^{-1}\|_2\|\mathbf{r}\|_2,$$

   where $\|\mathbf{z}\|_M = \sqrt{\mathbf{z}^*M\mathbf{z}}$.

   (b) Let μ be the closest eigenvalue to $\widetilde{\mu}$ among all eigenvalues of $A - \lambda B$ and $\mathbf{x}$ its associated eigenvector with $\|\mathbf{x}\|_2 = 1$, and let $\eta = \min|\widetilde{\mu} - \nu|$ over all other eigenvalues $\nu \neq \mu$ of $A - \lambda B$. If $\eta > 0$, then

   $$|\widetilde{\mu} - \mu| \leq \frac{1}{\eta}\cdot\left(\frac{\|\mathbf{r}\|_{B^{-1}}}{\|\widetilde{\mathbf{x}}\|_B}\right)^2 \leq \|B^{-1}\|_2^2\frac{\|\mathbf{r}\|_2^2}{\eta},$$
   $$\sin\angle(\widetilde{\mathbf{x}}, \mathbf{x}) \leq \|B^{-1}\|_2\sqrt{2\kappa_2(B)}\,\frac{\|\mathbf{r}\|_2}{\eta}.$$

10. [Li94] Suppose $A - \lambda B$ and $\widetilde{A} - \lambda\widetilde{B}$ are diagonalizable and have eigendecompositions

   $$\begin{bmatrix} Y_1^* \\ Y_2^* \end{bmatrix} A[X_1,\ X_2] = \begin{bmatrix} \Lambda_1 & \\ & \Lambda_2 \end{bmatrix}, \begin{bmatrix} Y_1^* \\ Y_2^* \end{bmatrix} B[X_1,\ X_2] = \begin{bmatrix} \Omega_1 & \\ & \Omega_2 \end{bmatrix},$$

   $$X^{-1} = [W_1,\ W_2]^*,$$

   and the same for $\widetilde{A} - \lambda\widetilde{B}$ except all symbols with tildes, where $X_1, Y_1, W_1 \in \mathbb{C}^{n\times k}$, $\Lambda_1, \Omega_1 \in \mathbb{C}^{k\times k}$. Suppose $|\alpha_j|^2 + |\beta_j|^2 = |\widetilde{\alpha}_j|^2 + |\widetilde{\beta}_j|^2 = 1$ for $1 \leq j \leq n$ in the eigendecompositions, and set $\eta = \min\chi\big(\langle\alpha,\beta\rangle, \langle\widetilde{\alpha},\widetilde{\beta}\rangle\big)$ taken over all $\langle\alpha,\beta\rangle \in \sigma(\Lambda_1, \Omega_1)$ and $\langle\widetilde{\alpha},\widetilde{\beta}\rangle \in \sigma(\widetilde{\Lambda}_2, \widetilde{\Omega}_2)$. If $\eta > 0$, then

   $$\left\|\sin\Theta(X_1, \widetilde{X}_1)\right\|_{\text{F}} \leq \frac{\|X_1^\dagger\|_2\|\widetilde{W}_2^\dagger\|_2}{\eta}\left\|\widetilde{Y}_2^*(\widetilde{Z} - Z)\begin{bmatrix} X_1 & \\ & X_1 \end{bmatrix}\right\|_{\text{F}}.$$

   Under a stronger separation condition between $\sigma(\Lambda_1, \Omega_1)$ and $\sigma(\widetilde{\Lambda}_2, \widetilde{\Omega}_2)$, bounds in terms of any unitarily invariant norm are also available.

21.5 Generalized Singular Value Problems

Definitions:

Let $A \in \mathbb{C}^{m\times n}$ and $B \in \mathbb{C}^{\ell\times n}$. A matrix pair $\{A, B\}$ is an (m, ℓ, n)-**Grassmann matrix pair** if $\operatorname{rank}\left(\begin{bmatrix} A \\ B \end{bmatrix}\right) = n$.

In what follows, all matrix pairs are (m, ℓ, n)-Grassmann matrix pairs.

A pair $\langle \alpha, \beta\rangle$ is a **generalized singular value** of $\{A, B\}$ if

$$\det(\beta^2 A^* A - \alpha^2 B^* B) = 0,\ \langle \alpha, \beta\rangle \neq \langle 0, 0\rangle,\ \alpha,\ \beta \geq 0,$$

i.e., $\langle \alpha, \beta\rangle = \langle \sqrt{\mu}, \sqrt{\nu}\rangle$ for some generalized eigenvalue $\langle \mu, \nu\rangle$ of matrix pencil $A^*A - \lambda B^*B$.

Generalized Singular Value Decomposition (GSVD) of $\{A, B\}$:

$$U^* A X = \Sigma_A, \quad V^* B X = \Sigma_B,$$

where $U \in \mathbb{C}^{m\times m}$, $V \in \mathbb{C}^{\ell\times\ell}$ are unitary, $X \in \mathbb{C}^{n\times n}$ is nonsingular, $\Sigma_A = \operatorname{diag}(\alpha_1, \alpha_2, \cdots)$ is **leading diagonal** (α_j starts in the top left corner), and $\Sigma_B = \operatorname{diag}(\cdots, \beta_{n-1}, \beta_n)$ is **trailing diagonal** (β_j ends in the bottom-right corner), α_j, $\beta_j \geq 0$ and $\alpha_j^2 + \beta_j^2 = 1$ for $1 \leq j \leq n$. (Set some $\alpha_j = 0$ and some $\beta_j = 0$, if necessary.)

$\{A, B\}$ is perturbed to $\{\widetilde{A}, \widetilde{B}\} = \{A + \Delta A, B + \Delta B\}$.

Let $\operatorname{SV}(A, B) = \{\langle \alpha_1, \beta_1\rangle, \langle \alpha_2, \beta_2\rangle, \ldots, \langle \alpha_n, \beta_n\rangle\}$ be the set of the generalized singular values of $\{A, B\}$, and set $Z = \begin{bmatrix} A \\ B \end{bmatrix} \in \mathbb{C}^{(m+\ell)\times n}$.

The same notation is adopted for $\{\widetilde{A}, \widetilde{B}\}$, except all symbols with tildes.

Facts:

1. If $\{A, B\}$ is an (m, ℓ, n)-Grassmann matrix pair, then $A^*A - \lambda B^*B$ is a definite matrix pencil.
2. [Van76] The GSVD of an (m, ℓ, n)-Grassmann matrix pair $\{A, B\}$ exists.
3. [Li93] There exist permutations τ and ω of $\{1, 2, \ldots, n\}$ such that

$$\max_{1\leq j\leq n} \chi\big(\langle \alpha_i, \beta_i\rangle, \langle \widetilde{\alpha}_{\tau(i)}, \widetilde{\beta}_{\tau(i)}\rangle\big) \leq \|\sin\Theta(Z, \widetilde{Z})\|_2,$$

$$\sqrt{\sum_{j=1}^{n}\Big[\chi\big(\langle \alpha_i, \beta_i\rangle, \langle \widetilde{\alpha}_{\omega(i)}, \widetilde{\beta}_{\omega(i)}\rangle\big)\Big]^2} \leq \|\sin\Theta(Z, \widetilde{Z})\|_{\mathrm{F}}.$$

4. [Li94, Lemma 3.3] (**Sun**)

$$\|\sin\Theta(Z, \widetilde{Z})\|_{\mathrm{UI}} \leq \frac{\|Z - \widetilde{Z}\|_{\mathrm{UI}}}{\max\{\sigma_{\min}(Z),\ \sigma_{\min}(\widetilde{Z})\}},$$

   where $\sigma_{\min}(Z)$ is Z's smallest singular value.

5. [Pai84] If $\alpha_i^2 + \beta_i^2 = \widetilde{\alpha}_i^2 + \widetilde{\beta}_i^2 = 1$ for $i = 1, 2, \ldots, n$, then there exists a permutation ϖ of $\{1, 2, \ldots, n\}$ such that

$$\sqrt{\sum_{j=1}^{n}\Big[(\alpha_j - \widetilde{\alpha}_{\varpi(j)})^2 + (\beta_j - \widetilde{\beta}_{\varpi(j)})^2\Big]} \leq \min_{Q \text{ unitary}} \|Z_0 - \widetilde{Z}_0 Q\|_{\mathrm{F}},$$

   where $Z_0 = Z(Z^*Z)^{-1/2}$ and $\widetilde{Z}_0 = \widetilde{Z}(\widetilde{Z}^*\widetilde{Z})^{-1/2}$.

6. [Li93], [Sun83] Perturbation bounds on generalized singular subspaces (those spanned by one or a few columns of U, V, and X in GSVD) are also available, but it is quite complicated.

21.6 Relative Perturbation Theory for Eigenvalue Problems

Definitions:

Let scalar $\widetilde{\alpha}$ be an approximation to α, and $1 \le p \le \infty$.

Define **relative distances** between α and $\widetilde{\alpha}$ as follows. For $|\alpha|^2 + |\widetilde{\alpha}|^2 \ne 0$,

$$\begin{aligned} d(\alpha, \widetilde{\alpha}) &= \left| \frac{\widetilde{\alpha}}{\alpha} - 1 \right| = \frac{|\widetilde{\alpha} - \alpha|}{|\alpha|}, && \text{(classical measure)} \\ \varrho_p(\alpha, \widetilde{\alpha}) &= \frac{|\widetilde{\alpha} - \alpha|}{\sqrt[p]{|\alpha|^p + |\widetilde{\alpha}|^p}}, && \text{([Li98])} \\ \zeta(\alpha, \widetilde{\alpha}) &= \frac{|\widetilde{\alpha} - \alpha|}{\sqrt{|\alpha\widetilde{\alpha}|}}, && \text{([BD90], [DV92])} \\ \varsigma(\alpha, \widetilde{\alpha}) &= |\ln(\widetilde{\alpha}/\alpha)|, \quad \text{for } \widetilde{\alpha}\alpha > 0, && \text{([LM99a], [Li99b])} \end{aligned}$$

and $d(0,0) = \varrho_p(0,0) = \zeta(0,0) = \varsigma(0,0) = 0$.

$A \in \mathbb{C}^{n\times n}$ is **multiplicatively perturbed** to $\widetilde{A}$ if $\widetilde{A} = D_{\mathrm{L}}^* A D_{\mathrm{R}}$ for some D_{L}, $D_{\mathrm{R}} \in \mathbb{C}^{n\times n}$.

Denote $\sigma(A) = \{\lambda_1, \lambda_2, \ldots, \lambda_n\}$ and $\sigma(\widetilde{A}) = \{\widetilde{\lambda}_1, \widetilde{\lambda}_2, \ldots, \widetilde{\lambda}_n\}$.

$A \in \mathbb{C}^{n\times n}$ is said to be **graded** if it can be scaled as $A = S^*HS$ such that H is "well-behaved" (i.e., $\kappa_2(H)$ is of modest magnitude), where S is a scaling matrix, often diagonal but not required so for the facts below. Interesting cases are when $\kappa_2(H) \ll \kappa_2(A)$.

Facts:

1. [Bar00] $\varrho_p(\,\cdot\,,\,\cdot\,)$ is a metric on $\mathbb{C}$ for $1 \le p \le \infty$.
2. Let $A, \widetilde{A} = D^*AD \in \mathbb{C}^{n\times n}$ be Hermitian, where D is nonsingular.
   (a) [HJ85, p. 224] (**Ostrowski**) There exists t_j, satisfying

   $$\lambda_{\min}(D^*D) \le t_j \le \lambda_{\max}(D^*D),$$

   such that $\widetilde{\lambda}_j^{\uparrow} = t_j \lambda_j^{\uparrow}$ for $j = 1, 2, \ldots, n$ and, thus,

   $$\max_{1\le j\le n} d(\lambda_j^{\uparrow}, \widetilde{\lambda}_j^{\uparrow}) \le \|I - D^*D\|_2.$$

   (b) [LM99], [Li98]

   $$\begin{aligned} \|\mathrm{diag}\left(\varsigma(\lambda_1^{\uparrow}, \widetilde{\lambda}_1^{\uparrow}), \ldots, \varsigma(\lambda_n^{\uparrow}, \widetilde{\lambda}_n^{\uparrow})\right)\|_{\mathrm{UI}} &\le \|\ln(D^*D)\|_{\mathrm{UI}}, \\ \|\mathrm{diag}\left(\zeta(\lambda_1^{\uparrow}, \widetilde{\lambda}_1^{\uparrow}), \ldots, \zeta(\lambda_n^{\uparrow}, \widetilde{\lambda}_n^{\uparrow})\right)\|_{\mathrm{UI}} &\le \|D^* - D^{-1}\|_{\mathrm{UI}}. \end{aligned}$$

3. [Li98], [LM99] Let $A = S^*HS$ be a positive semidefinite Hermitian matrix, perturbed to $\widetilde{A} = S^*(H + \Delta H)S$. Suppose H is positive definite and $\|H^{-1/2}(\Delta H)H^{-1/2}\|_2 < 1$, and set

   $$M = H^{1/2}SS^*H^{1/2}, \quad \widetilde{M} = DMD,$$

where $D = \left[I + H^{-1/2}(\Delta H)H^{-1/2}\right]^{1/2} = D^*$. Then $\sigma(A) = \sigma(M)$ and $\sigma(\widetilde{A}) = \sigma(\widetilde{M})$, and the inequalities in Fact 2 hold with D here. Note that

$$\|D - D^{-1}\|_{\text{UI}} \leq \frac{\|H^{-1/2}(\Delta H)H^{-1/2}\|_{\text{UI}}}{\sqrt{1 - \|H^{-1/2}(\Delta H)H^{-1/2}\|_2}}$$
$$\leq \frac{\|H^{-1}\|_2}{\sqrt{1 - \|H^{-1}\|_2\|\Delta H\|_2}}\,\|\Delta H\|_{\text{UI}}.$$

4. [BD90], [VS93] Suppose A and $\widetilde{A}$ are Hermitian, and let $|A| = (A^2)^{1/2}$ be the positive semidefinite square root of A^2. If there exists $0 \leq \delta < 1$ such that

$$|\mathbf{x}^*(\Delta A)\mathbf{x}| \leq \delta \mathbf{x}^*|A|\mathbf{x} \quad \text{for all } \mathbf{x} \in \mathbb{C}^n,$$

then either $\widetilde{\lambda}_j^{\uparrow} = \lambda_j^{\uparrow} = 0$ or $1 - \delta \leq \widetilde{\lambda}_j^{\uparrow}/\lambda_j^{\uparrow} \leq 1 + \delta$.

5. [Li99a] Let Hermitian A, $\widetilde{A} = D^*AD$ have decompositions

$$\begin{bmatrix} X_1^* \\ X_2^* \end{bmatrix} A[X_1\ X_2] = \begin{bmatrix} A_1 & \\ & A_2 \end{bmatrix}, \quad \begin{bmatrix} \widetilde{X}_1^* \\ \widetilde{X}_2^* \end{bmatrix} \widetilde{A}[\widetilde{X}_1\ \widetilde{X}_2] = \begin{bmatrix} \widetilde{A}_1 & \\ & \widetilde{A}_2 \end{bmatrix},$$

where $[X_1\ X_2]$ and $[\widetilde{X}_1\ \widetilde{X}_2]$ are unitary and $X_1, \widetilde{X}_1 \in \mathbb{C}^{n\times k}$.

(a) Let $\eta_2 = \min\limits_{\mu\in\sigma(A_1),\,\widetilde{\mu}\in\sigma(\widetilde{A}_2)} \varrho_2(\mu, \widetilde{\mu}) > 0$. If $\eta_2 > 0$, then

$$\|\sin\Theta(X_1, \widetilde{X}_1)\|_{\text{F}} \leq \frac{\sqrt{\|(I - D^{-1})X_1\|_{\text{F}}^2 + \|(I - D^*)X_1\|_{\text{F}}^2}}{\eta_2}.$$

(b) If there are $\alpha \geq 0$ and $\delta > 0$ such that either

$$\sigma(A_1) \subseteq [-\alpha, \alpha],\ \sigma(\widetilde{A}_2) \subset (-\infty, -\alpha - \delta] \cup [\alpha + \delta, \infty)$$

or

$$\sigma(A_1) \subset (-\infty, -\alpha - \delta] \cup [\alpha + \delta, \infty),\ \sigma(\widetilde{A}_2) \subseteq [-\alpha, \alpha],$$

then

$$\|\sin\Theta(X_1, \widetilde{X}_1)\|_{\text{UI}} \leq \frac{\sqrt[q]{\|(I - D^{-1})X_1\|_{\text{UI}}^q + \|(I - D^*)X_1\|_{\text{UI}}^q}}{\varrho_p(\alpha, \alpha + \delta)},$$

where $1/p + 1/q = 1$.

6. Let $A = S^*HS$ be a positive semidefinite Hermitian matrix, perturbed to $\widetilde{A} = S^*(H + \Delta H)S$, having decompositions, in notation, the same as in Fact 5. Suppose H is positive definite and $\|H^{-1/2}(\Delta H)H^{-1/2}\|_2 < 1$, and let

$$D = \left[I + H^{-1/2}(\Delta H)H^{-1/2}\right]^{1/2}.$$

(a) [Li99a], [Li99b] Let $\eta_\zeta = \min\limits_{\mu\in\sigma(A_1),\,\widetilde{\mu}\in\sigma(\widetilde{A}_2)} \zeta(\mu, \widetilde{\mu})$ and $\eta_\varsigma = \min\limits_{\mu\in\sigma(A_1),\,\widetilde{\mu}\in\sigma(\widetilde{A}_2)} \varsigma(\mu, \widetilde{\mu})$. If $\eta_\zeta > 0$ (and thus $\eta_\varsigma > 0$, too), then

$$\|\sin\Theta(X_1, \widetilde{X}_1)\|_{\text{F}} \leq \frac{\|D - D^{-1}\|_{\text{F}}}{\eta_\zeta}, \quad \|\sin\Theta(X_1, \widetilde{X}_1)\|_{\text{UI}} \leq \frac{\pi}{2} \cdot \frac{\|D - D^{-1}\|_{\text{UI}}}{\eta_\varsigma}.$$

(b) [Li99a] If $\sigma(A_1)$ and $\sigma(\widetilde{A}_2)$ are separated as in Fact 5(b), then

$$\|\sin\Theta(X_1,\widetilde{X}_1)\|_{\text{UI}} \le \frac{\|D-D^{-1}\|_{\text{UI}}}{\zeta(\alpha,\alpha+\delta)}.$$

Examples:

1. [DK90], [EI95] Let A be a real symmetric tridiagonal matrix with zero diagonal and off-diagonal entries $b_1, b_2, \dots, b_{n-1}$. Suppose $\widetilde{A}$ is identical to A except for its off-diagonal entries which change to $\beta_1 b_1, \beta_2 b_2, \dots, \beta_{n-1} b_{n-1}$, where all β_i are real and supposedly close to 1. Then $\widetilde{A} = DAD$, where $D = \operatorname{diag}(d_1, d_2, \dots, d_n)$ with

$$d_{2k} = \frac{\beta_1\beta_3\cdots\beta_{2k-1}}{\beta_2\beta_4\cdots\beta_{2k-2}}, \quad d_{2k+1} = \frac{\beta_2\beta_4\cdots\beta_{2k}}{\beta_1\beta_3\cdots\beta_{2k-1}}.$$

Let $\beta = \prod_{j=1}^{n-1}\max\{\beta_j, 1/\beta_j\}$. Then $\beta^{-1}I \le D^2 \le \beta I$, and Fact 2 and Fact 5 apply. Now if all $1-\varepsilon \le \beta_j \le 1+\varepsilon$, then $(1-\varepsilon)^{n-1} \le \beta^{-1} \le \beta \le (1+\varepsilon)^{n-1}$.

2. Let $A = SHS$ with $S = \operatorname{diag}(1, 10, 10^2, 10^3)$, and

$$A = \begin{bmatrix} 1 & 1 & & \\ 1 & 10^2 & 10^2 & \\ & 10^2 & 10^4 & 10^4 \\ & & 10^4 & 10^6 \end{bmatrix}, \quad H = \begin{bmatrix} 1 & 10^{-1} & & \\ 10^{-1} & 1 & 10^{-1} & \\ & 10^{-1} & 1 & 10^{-1} \\ & & 10^{-1} & 1 \end{bmatrix}.$$

Suppose that each entry A_{ij} of A is perturbed to $A_{ij}(1+\delta_{ij})$ with $|\delta_{ij}| \le \varepsilon$. Then $|(\Delta H)_{ij}| \le \varepsilon|H_{ij}|$ and thus $\|\Delta H\|_2 \le 1.2\varepsilon$. Since $\|H^{-1}\|_2 \le 10/8$, Fact 3 implies

$$\zeta(\lambda_j^{\uparrow}, \widetilde{\lambda}_j^{\uparrow}) \le 1.5\varepsilon/\sqrt{1-1.5\varepsilon} \approx 1.5\varepsilon.$$

21.7 Relative Perturbation Theory for Singular Value Problems

Definitions:

$B \in \mathbb{C}^{m\times n}$ is **multiplicatively perturbed** to $\widetilde{B}$ if $\widetilde{B} = D_{\text{L}}^* B D_{\text{R}}$ for some $D_{\text{L}} \in \mathbb{C}^{m\times m}$ and $D_{\text{R}} \in \mathbb{C}^{n\times n}$.

Denote the singular values of B and $\widetilde{B}$ as

$$\text{sv}(B) = \{\sigma_1, \sigma_2, \dots, \sigma_{\min\{m,n\}}\}, \quad \text{sv}(\widetilde{B}) = \{\widetilde{\sigma}_1, \widetilde{\sigma}_2, \dots, \widetilde{\sigma}_{\min\{m,n\}}\}.$$

B is said to be (highly) **graded** if it can be scaled as $B = GS$ such that G is "well-behaved" (i.e., $\kappa_2(G)$ is of modest magnitude), where S is a scaling matrix, often diagonal but not required so for the facts below. Interesting cases are when $\kappa_2(G) \ll \kappa_2(B)$.

Facts:

1. Let B, $\widetilde{B} = D_{\text{L}}^* B D_{\text{R}} \in \mathbb{C}^{m\times n}$, where D_{L} and D_{R} are nonsingular.

   (a) [EI95] For $1 \le j \le n$, $\dfrac{\sigma_j}{\|D_{\text{L}}^{-1}\|_2\|D_{\text{R}}^{-1}\|_2} \le \widetilde{\sigma}_j \le \sigma_j\, \|D_{\text{L}}\|_2\|D_{\text{R}}\|_2$.

   (b) [Li98], [LM99]

$$\begin{aligned}&\|\mathrm{diag}\left(\zeta(\sigma_1,\widetilde{\sigma}_1),\ldots,\zeta(\sigma_n,\widetilde{\sigma}_n)\right)\|_{\mathrm{UI}}\\&\le\frac{1}{2}\|D_{\mathrm{L}}^*-D_{\mathrm{L}}^{-1}\|_{\mathrm{UI}}+\frac{1}{2}\|D_{\mathrm{R}}^*-D_{\mathrm{R}}^{-1}\|_{\mathrm{UI}}.\end{aligned}$$

2. [Li99a] Let B, $\widetilde{B}=D_{\mathrm{L}}^*BD_{\mathrm{R}}\in\mathbb{C}^{m\times n}$ $(m\ge n)$ have decompositions

$$\begin{bmatrix}U_1^*\\U_2^*\end{bmatrix}B[V_1\ V_2]=\begin{bmatrix}B_1&0\\0&B_2\end{bmatrix},\quad\begin{bmatrix}\widetilde{U}_1^*\\\widetilde{U}_2^*\end{bmatrix}\widetilde{B}[\widetilde{V}_1\ \widetilde{V}_2]=\begin{bmatrix}\widetilde{B}_1&0\\0&\widetilde{B}_2\end{bmatrix},$$

where $[U_1\ U_2]$, $[V_1\ V_2]$, $[\widetilde{U}_1\ \widetilde{U}_2]$, and $[\widetilde{V}_1\ \widetilde{V}_2]$ are unitary, and U_1, $\widetilde{U}_1\in\mathbb{C}^{m\times k}$, V_1, $\widetilde{V}_1\in\mathbb{C}^{n\times k}$.

(a) Let $\eta_2=\min\varrho_2(\mu,\widetilde{\mu})$ over all $\mu\in\mathrm{SV}(B_1)$ and $\widetilde{\mu}\in\mathrm{SV}_{\mathrm{ext}}(\widetilde{B}_2)$. If $\eta_2>0$, then

$$\begin{aligned}&\sqrt{\|\sin\Theta(U_1,\widetilde{U}_1)\|_{\mathrm{F}}^2+\|\sin\Theta(V_1,\widetilde{V}_1)\|_{\mathrm{F}}^2}\\&\le\frac{1}{\eta_2}\left[\|(I-D_{\mathrm{L}}^*)U_1\|_{\mathrm{F}}^2+\|(I-D_{\mathrm{L}}^{-1})U_1\|_{\mathrm{F}}^2\right.\\&\qquad\left.+\|(I-D_{\mathrm{R}}^*)V_1\|_{\mathrm{F}}^2+\|(I-D_{\mathrm{R}}^{-1})V_1\|_{\mathrm{F}}^2\right]^{1/2}.\end{aligned}$$

(b) If there are $\alpha\ge 0$ and $\delta>0$ such that

$$\widetilde{\mu}\ge\alpha+\delta\text{ for }\widetilde{\mu}\in\mathrm{SV}(\widetilde{B}_1),\text{ and }\nu\le\alpha\text{ for }\nu\in\mathrm{SV}_{\mathrm{ext}}(B_2),$$

then

$$\begin{aligned}&\max\left\{\|\sin\Theta(U_1,\widetilde{U}_1)\|_{\mathrm{UI}},\ \|\sin\Theta(V_1,\widetilde{V}_1)\|_{\mathrm{UI}}\right\}\\&\le\frac{1}{\eta_p}\max\left\{\sqrt[q]{\|(I-D_{\mathrm{R}}^{-1})V_1\|_{\mathrm{UI}}^q+\|(I-D_{\mathrm{L}}^*)U_1\|_{\mathrm{UI}}^q},\right.\\&\qquad\qquad\left.\sqrt[q]{\|(I-D_{\mathrm{L}}^{-1})U_1\|_{\mathrm{UI}}^q+\|(I-D_{\mathrm{R}}^*)V_1\|_{\mathrm{UI}}^q}\right\}.\end{aligned}$$

where $\eta_p=\varrho_p(\alpha,\alpha+\delta)$ and $1/p+1/q=1$.

3. [Li98], [Li99a], [LM99] Let $B=GS$ and $\widetilde{B}=\widetilde{G}S$ be two $m\times n$ matrices, where $\mathrm{rank}(G)=n$, and let $\Delta G=\widetilde{G}-G$. Then $\widetilde{B}=DB$, where $D=I+(\Delta G)G^{\uparrow}$. Fact 1 and Fact 2 apply with $D_{\mathrm{L}}=D$ and $D_{\mathrm{R}}=I$. Note that

$$\|D^*-D^{-1}\|_{\mathrm{UI}}\le\left(1+\frac{1}{1-\|(\Delta G)G^{\uparrow}\|_2}\right)\frac{\|(\Delta G)G^{\uparrow}\|_{\mathrm{UI}}}{2}.$$

Examples:

1. [BD90], [DK90], [EI95] B is a real bidiagonal matrix with diagonal entries $a_1,a_2,\ldots,a_n$ and off-diagonal (the one above the diagonal) entries are $b_1,b_2,\ldots,b_{n-1}$. $\widetilde{B}$ is the same as B, except for its diagonal entries, which change to $\alpha_1a_1,\alpha_2a_2,\ldots,\alpha_na_n$, and its off-diagonal entries, which change to $\beta_1b_1,\beta_2b_2,\ldots,\beta_{n-1}b_{n-1}$. Then $\widetilde{B}=D_{\mathrm{L}}^*BD_{\mathrm{R}}$ with

$$D_{\mathrm{L}} = \operatorname{diag}\left(\alpha_1, \frac{\alpha_1\alpha_2}{\beta_1}, \frac{\alpha_1\alpha_2\alpha_3}{\beta_1\beta_2}, \ldots\right),$$
$$D_{\mathrm{R}} = \operatorname{diag}\left(1, \frac{\beta_1}{\alpha_1}, \frac{\beta_1\beta_2}{\alpha_1\alpha_2}, \ldots\right).$$

Let $\alpha = \prod_{j=1}^{n} \max\{\alpha_j, 1/\alpha_j\}$ and $\beta = \prod_{j=1}^{n-1} \max\{\beta_j, 1/\beta_j\}$. Then

$$(\alpha\beta)^{-1} \le \left(\|D_{\mathrm{L}}^{-1}\|_2 \|D_{\mathrm{R}}^{-1}\|_2\right)^{-1} \le \|D_{\mathrm{L}}\|_2 \|D_{\mathrm{R}}\|_2 \le \alpha\beta,$$

and Fact 1 and Fact 2 apply. Now if all $1-\varepsilon \le \alpha_i,\ \beta_j \le 1+\varepsilon$, then $(1-\varepsilon)^{2n-1} \le (\alpha\beta)^{-1} \le (\alpha\beta) \le (1+\varepsilon)^{2n-1}$.

2. Consider block partitioned matrices

$$B = \begin{bmatrix} B_{11} & B_{12} \\ 0 & B_{22} \end{bmatrix},$$
$$\widetilde{B} = \begin{bmatrix} B_{11} & 0 \\ 0 & B_{22} \end{bmatrix} = B \begin{bmatrix} I & -B_{11}^{-1}B_{12} \\ 0 & I \end{bmatrix} = BD_{\mathrm{R}}.$$

By Fact 2, $\zeta(\sigma_j, \widetilde{\sigma}_j) \le \frac{1}{2}\|B_{11}^{-1}B_{12}\|_2$. Interesting cases are when $\|B_{11}^{-1}B_{12}\|_2$ is tiny enough to be treated as zero and so $\mathrm{SV}(\widetilde{B})$ approximates $\mathrm{SV}(B)$ well. This situation occurs in computing the SVD of a bidiagonal matrix.

Matrices are like living beings: though following a simple and uniform building plan, they occur in unbelievable diversity, each having features we should treat with caution on the one hand and nice peculiarities we could take advantage of on the other. Working with matrices is therefore associating oneself with individuals of special types. A chapter like this requires making a selection from many types, and we decided to focus our attention on a few important classes of structured matrices. Even within our narrow selection, we encounter a huge variety of topics and deep theorems, which caused us to make another short-list. Thus, the following is a record reflecting our subjective taste, and we are well aware that our compilation is highly incomplete.

22.1 Circulant Matrices

Circulant matrices are very special Toeplitz matrices and hence deserve their own section.

Definitions:

Given $a_0, a_1, a_2, \dots, a_{n-1} \in \mathbb{C}$, the **circulant matrix** with first column $[a_0, a_1, a_2, \dots, a_{n-1}]^\top$ is the matrix

$$\operatorname{circ}(a_0, a_1, a_2, \dots, a_{n-1}) := \begin{bmatrix} a_0 & a_{n-1} & a_{n-2} & \dots & a_1 \\ a_1 & a_0 & a_{n-1} & \dots & a_2 \\ a_2 & a_1 & a_0 & \dots & a_3 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n-1} & a_{n-2} & a_{n-3} & \dots & a_0 \end{bmatrix}.$$

The **n-cycle matrix** C_n is the $n \times n$ circulant matrix with ones along the subdiagonal and in the upper right corner and zeros elsewhere, that is,

$$C_n := \operatorname{circ}(0, 1, 0, \dots, 0) = \begin{bmatrix} 0 & 0 & \dots & 0 & 1 \\ 1 & 0 & 0 & & 0 \\ \vdots & 1 & 0 & \ddots & \vdots \\ 0 & & \ddots & \ddots & 0 \\ 0 & 0 & \dots & 1 & 0 \end{bmatrix}.$$

Let $\omega_n := \exp(2\pi i/n)$. The matrix

$$F_n := \frac{1}{\sqrt{n}}\left[\omega_n^{(j-1)(k-1)}\right]_{j,k=1}^{n} = \frac{1}{\sqrt{n}}\begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n & \omega_n^2 & \dots & \omega_n^{n-1} \\ 1 & \omega_n^2 & \omega_n^4 & \dots & \omega_n^{2(n-1)} \\ \vdots & \vdots & \vdots & & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{2(n-1)} & \dots & \omega_n^{(n-1)(n-1)} \end{bmatrix} \tag{22.1}$$

is called the **Fourier matrix** of order n.

Facts:

1. $\operatorname{circ}(a_0, a_1, a_2, \dots, a_{n-1})^* = \operatorname{circ}(\,\overline{a_0}, \overline{a_{n-1}}, \overline{a_{n-2}}, \dots, \overline{a_1}\,)$.
2. $C_n^n = I_n$ and $C_n^{-1} = C_n^{n-1} = C_n^\top$.
3. [Dav79, p. 67] An $n \times n$ matrix A is a circulant if and only if $C_n A C_n^\top = A$.
4. [Dav79, p. 68] Every circulant matrix can be expressed as a polynomial in C_n:
$$\operatorname{circ}(a_0, a_1, a_2, \dots, a_{n-1}) = a_0 I_n + a_1 C_n + a_2 C_n^2 + \dots + a_{n-1} C_n^{n-1}.$$
5. [Dav79, p. 33] The matrix F_n is unitary,
$$F_n^{-1} = F_n^* = (1/\sqrt{n})\,\left[\overline{\omega}_n^{(j-1)(k-1)}\right]_{j,k=1}^{n}.$$
6. [MP72] The characteristic polynomial of the Fourier matrix is
$$\det(\lambda I - F_n) = (\lambda - 1)^{\lfloor (n+4)/4 \rfloor}(\lambda + 1)^{\lfloor (n+2/4 \rfloor}(\lambda - i)^{\lfloor (n+1)/4 \rfloor}(\lambda + i)^{\lfloor (n-1)/4 \rfloor},$$
where $\lfloor p \rfloor$ denotes the integral part of p (greatest integer function of p).
7. [Dav79, p. 72] Circulant matrices are unitarily diagonalizable. To be more specific, letting $a(z) := a_0 + a_1 z + \dots + a_{n-1} z^{n-1}$, we have the following:
   (a) $\operatorname{circ}(a_0, a_1, a_2, \dots, a_{n-1}) = F_n^* \operatorname{diag}[a(1), a(\omega_n), a(\omega_n^2), \dots, a(\omega_n^{n-1})]\, F_n$,
   (b) the eigenvalues of $\operatorname{circ}(a_0, a_1, a_2, \dots, a_{n-1})$ are $a(\omega_n^j)$ $(j = 0, 1, \dots, n-1)$,
   (c) the complex conjugate of the jth column of the matrix F_n, that is, the column $(1/\sqrt{n})\,[1, \overline{\omega}_n^j, \overline{\omega}_n^{2j}, \dots, \overline{\omega}_n^{(n-1)j}]^\top$ is a normalized eigenvector for $a(\omega_n^j)$.
8. [Dav79, p. 68] If A and B are circulant matrices, then $AB = BA$. Circulant matrices are in particular normal.

Examples:

1. Here are a 4×4 circulant matrix A and the Fourier matrix F_4:
$$A = \begin{bmatrix} 1 & 4 & 3 & 2 \\ 2 & 1 & 4 & 3 \\ 3 & 2 & 1 & 4 \\ 4 & 3 & 2 & 1 \end{bmatrix}, \quad F_4 = \frac{1}{2}\begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & i & -1 & -i \\ 1 & -1 & 1 & -1 \\ 1 & -i & -1 & i \end{bmatrix}.$$
We have $a(z) = 1 + 2z + 3z^2 + 4z^3$ and hence the eigenvalues of A are
$$\{a(1), a(i), a(-1), a(-i)\} = \{10, -2 - 2\,i, -2, -2 + 2\,i\}.$$
The normalized eigenvectors delivered by the complex conjugates of the columns of F_4 are
$$\frac{1}{2}[1, 1, 1, 1]^\top, \quad \frac{1}{2}[1, -i - 1, i]^\top, \quad \frac{1}{2}[1, -1, 1, -1]^\top, \quad \frac{1}{2}[1, i, -1, -i]^\top.$$

2. By Fact 6, the matrix F_4 has the eigenvalue 1 with multiplicity 2 and the two simple eigenvalues -1 and i.

22.2 Toeplitz Matrices

Definitions:

An $n \times n$ **Toeplitz matrix** is a matrix of the form

$$T_n := [a_{i-j}]_{i,j=0}^{n-1} = \begin{bmatrix} a_0 & a_{-1} & a_{-2} & \cdots & a_{-(n-1)} \\ a_1 & a_0 & a_{-1} & \cdots & a_{-(n-2)} \\ a_2 & a_1 & a_0 & \cdots & a_{-(n-3)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n-1} & a_{n-2} & a_{n-3} & \cdots & a_0 \end{bmatrix}. \tag{22.2}$$

(We sometimes index the entries of an $n \times n$ matrix A starting with 0, denoted as $A = [a_{ij}]_{i,j=0}^{n-1}$, and sometimes in the more customary way starting at 1, denoted as $A = [a_{ij}]_{i,j=1}^{n}$. In each case the indexing is identified.)

Frequently it is convenient to think of T_n as the principal $n \times n$ truncation of the infinite Toeplitz matrix

$$T := [a_{i-j}]_{i,j=0}^{\infty} = \begin{bmatrix} a_0 & a_{-1} & a_{-2} & \cdots \\ a_1 & a_0 & a_{-1} & \cdots \\ a_2 & a_1 & a_0 & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix}, \tag{22.3}$$

The entries a_k are complex numbers. If the function $a(z) := \sum_{k=-\infty}^{\infty} a_k z^k$ is well defined for $z = e^{i\theta}$ on the complex unit circle $\mathbb{T}$, it is referred to as the **symbol** of the matrix (22.3), and in that case the matrices (22.2) and (22.3) are denoted by $T_n(a)$ and $T(a)$, respectively.

The **Toeplitz Bezoutian** associated with two vectors $\mathbf{u} := [u_j]_{j=0}^{n}$ and $\mathbf{v} := [v_j]_{j=0}^{n}$ in $\mathbb{C}^{n+1}$ is the $n \times n$ matrix

$$\mathrm{Bez}(\mathbf{u},\mathbf{v}) := \begin{bmatrix} u_0 & & \\ \vdots & \ddots & \\ u_{n-1} & \cdots & u_0 \end{bmatrix} \begin{bmatrix} v_n & \cdots & v_1 \\ & \ddots & \vdots \\ & & v_n \end{bmatrix} - \begin{bmatrix} v_0 & & \\ \vdots & \ddots & \\ v_{n-1} & \cdots & v_0 \end{bmatrix} \begin{bmatrix} u_n & \cdots & u_1 \\ & \ddots & \vdots \\ & & u_n \end{bmatrix}.$$

This is in general not a Toeplitz matrix; the attribute Toeplitz is rather needed to distinguish Toeplitz Bezoutians from Hankel Bezoutians, which will be defined in Section 22.3. The **generating polynomial** of a matrix $B = [b_{ij}]_{i,jj=0}^{n-1}$ is the polynomial of two variables defined by $B(t,s) := \sum_{i,j=0}^{n-1} b_{ij} t^i s^j$.

Let l^2 be the Hilbert space of all square-summable complex sequences $(x_k)_{k=1}^{\infty}$ as in Fact 5.1.5 and define the operators P_n and W_n on l^2 by

$$P_n : (x_1, x_2, \ldots) \mapsto (x_1, x_2, \ldots, x_n, 0, 0, \ldots), \tag{22.4}$$

$$W_n : (x_1, x_2, \ldots) \mapsto (x_n, x_{n-1}, \ldots, x_1, 0, 0, \ldots). \tag{22.5}$$

The spectral norm of a square matrix A is henceforth denoted by $\|A\|$, and the (spectral) condition number of an invertible square matrix A is $\kappa(A) := \|A\|\|A^{-1}\|$. We put $\kappa(A) := \infty$ if A is not invertible.

The set of continuous functions $\mathbb{T} \to \mathbb{C}$ is denoted by $C(\mathbb{T})$. We let $L^p(\mathbb{T})$ $(1 \le p \le \infty)$ stand for the usual Lebesgue spaces of complex-valued functions on $\mathbb{T}$. The norm of $f \in L^\infty(\mathbb{T})$ is defined by $\|f\|_\infty := \operatorname{ess\,sup}\{|a(z)| : z \in \mathbb{T}\}$, that is, $\|f\|_\infty$ is the infimum of all positive numbers m such that $|f(z)| \le m$ for almost all $z \in \mathbb{T}$.

We refer to Fact 23.2.1 for the definition of the Hausdorff metric.

Facts:

Most of the following facts can be found in [HR84], [HR10] (algebraic and computational issues) and [BS99], [BG05] (asymptotic properties). Sometimes a reference is provided for historical reasons.

1. $T_n(a) + T_n(b) = T_n(a+b)$, $T_n(\lambda a) = \lambda T_n(a)$ $(\lambda \in \mathbb{C})$.
2. $T_n(a)^\top = T_n(\tilde{a})$ and $T_n(a)^* = T_n(\overline{a})$ where $\tilde{a}(z) := a(\overline{z})$ and $\overline{a}(z) := \overline{a(z)}$ for $z \in \mathbb{T}$, the bar denoting complex conjugation.
3. [BH63] Suppose $a \in L^\infty(\mathbb{T})$. The matrices $T_n(a)$ are Hermitian for all $n \ge 1$ if and only if $a(z) \in \mathbb{R}$ for almost all $z \in \mathbb{T}$, and the matrices $T_n(a)$ are normal for all $n \ge 1$ if and only if there is a straight line $l \subset \mathbb{C}$ such that $a(z) \in l$ for almost all $z \in \mathbb{T}$.
4. [BH63], [BS99, p. 46] Let $M \subset \mathbb{C}$ be a convex set such that $a(z) \in M$ for almost all $z \in \mathbb{T}$. Then, for every $n \ge 1$, the eigenvalues of $T_n(a)$ are all located in M.
5. $\operatorname{Bez}(\mathbf{u}, \mathbf{v})^\top = \operatorname{Bez}(\tilde{\mathbf{v}}, \tilde{\mathbf{u}})$ where $\tilde{\mathbf{v}} := [v_{n-j}]_{j=0}^n$, $\tilde{\mathbf{u}} := [u_{n-j}]_{j=0}^n$.
6. [HR84, p. 32], [HR10, p. 41] A matrix $B = [b_{ij}]_{i,j=0}^{n-1}$ is a Toeplitz Bezoutian if and only if there exist polynomials $g(x) = g_0 + \cdots + g_n x^n$ and $h(x) = h_0 + \cdots + h_n x^n$ such that the generating polynomial is $B(t,s) = (g(t)h(s^{-1})s^n - h(t)g(s^{-1})s^n)/(1-ts)$.
7. [Lan74], [HR84, p. 36] (Lander's theorem) An invertible matrix is a Toeplitz Bezoutian if and only if it is the inverse of a Toeplitz matrix.
8. [HR10, p. 54] (Heinig and Rost's theorem) Suppose the matrix $T_n(a)$ is invertible. Denote by $\partial T_n(a)$ the $(n-1) \times (n+1)$ Toeplitz matrix which results from $T_n(a)$ by deleting the first row and adding a last column, taking the entry $a_{-(n-1)}$ from the original matrix,
$$\partial T_n(a) := \begin{bmatrix} a_1 & a_0 & \dots & a_{-(n-1)} \\ a_2 & a_1 & \dots & a_{-(n-2)} \\ \vdots & \vdots & & \vdots \\ a_{n-1} & a_{n-2} & \dots & a_{-1} \end{bmatrix}.$$
Then the null space of $\partial T_n(a)$ in $\mathbb{C}^{n+1}$ has the dimension 2. If $\{\mathbf{u}, \mathbf{v}\}$ is any basis in this null space, then there exists a nonzero constant c such that $T_n(a)^{-1} = c \operatorname{Bez}(\mathbf{u}, \mathbf{v})$.
9. [Tre64], [GS72], [HR84, p. 21] (Gohberg-Sementsul-Trench formula) Let $T_n(a)$ be invertible and let $\mathbf{x} = [x_j]_{j=0}^{n-1}$ and $\mathbf{y} = [y_j]_{j=0}^{n-1}$ be the solutions of the equations $T_n(a)\mathbf{x} = [1, 0, \dots, 0]^\top$ and $T_n(a)\mathbf{y} = [0, \dots, 0, 1]^\top$. If $x_0 \neq 0$, then the vectors $\mathbf{u} := \begin{bmatrix} \mathbf{x} \\ 0 \end{bmatrix} \in \mathbb{C}^{n+1}$ and $\mathbf{v} := \begin{bmatrix} 0 \\ \mathbf{y} \end{bmatrix} \in \mathbb{C}^{n+1}$ form a basis in the null space of $\partial T_n(a)$, and the equality $T_n(a)^{-1} = c \operatorname{Bez}(\mathbf{u}, \mathbf{v})$ becomes
$$T_n(a)^{-1} = \frac{1}{x_0} \begin{bmatrix} x_0 & & \\ \vdots & \ddots & \\ x_{n-1} & \dots & x_0 \end{bmatrix} \begin{bmatrix} y_{n-1} & \dots & y_0 \\ & \ddots & \vdots \\ & & y_{n-1} \end{bmatrix} - \frac{1}{x_0} \begin{bmatrix} y_{-1} & & \\ \vdots & \ddots & \\ y_{n-2} & \dots & y_{-1} \end{bmatrix} \begin{bmatrix} x_n & \dots & x_1 \\ & \ddots & \vdots \\ & & x_n \end{bmatrix}$$
with $x_n := 0$ and $y_{-1} := 0$.
10. [HR84, p. 17] (Heinig's formula) Suppose $T_n(a)$ is invertible and $\mathbf{x} = [x_i]_{i=0}^{n-1}$ and $\mathbf{q} = [q_i]_{i=0}^{n-1}$ are the solutions of the equations
$$T_n(a)\mathbf{x} = [1, 0, \dots, 0]^\top, \quad T_n(a)\mathbf{q} = [-a_{-n}, -a_{-(n-1)}, \dots, -a_{-1}]^\top,$$

where a_{-n} may be chosen arbitrarily. Then the two vectors $\mathbf{u} := \begin{bmatrix}\mathbf{x}\\0\end{bmatrix} \in \mathbb{C}^{n+1}$ and $\mathbf{v} := \begin{bmatrix}\mathbf{q}\\1\end{bmatrix} \in \mathbb{C}^{n+1}$ constitute a basis in the null space of $\partial T_n(a)$ and we have $T_n(a)^{-1} = \operatorname{Bez}(\mathbf{u}, \mathbf{v})$. Note that this formula does not require any additional condition such as $x_0 \neq 0$.

11. [BS99, p. 39](Baxter-Gohberg-Feldman theorem) If $a \in C(\mathbb{T})$, then the following are equivalent:

    (i) the matrices $T_n(a)$ are invertible for all sufficiently large n, say $n \geq n_0$, and there is a constant $M < \infty$ such that $\|T_n(a)^{-1}\| \leq M$ for all $n \geq n_0$;

    (ii) the function a has no zeros on $\mathbb{T}$ and its winding number about the origin is zero, that is, the curve $a(\mathbb{T})$ is homotopic to a point in $\mathbb{C} \setminus \{0\}$.
12. [Toe11](Toeplitz's theorem, from 1911 and not from 2011) The sequence $(\|T_n(a)\|)_{n=1}^{\infty}$ is monotonically nondecreasing. It remains bounded if and only if the symbol a is a function in $L^\infty(\mathbb{T})$, in which case the norms $\|T_n(a)\|$ converge to $\|a\|_\infty$.
13. [BG05, p. 122] We have $\|\underline{\sigma}_n a\|_\infty \leq \|T_n(a)\| \leq \|\overline{\sigma}_n a\|_\infty$ with

    $$(\underline{\sigma}_n a)(e^{i\theta}) := \sum_{|k|\leq n-1} a_k \left(1 - \frac{|k|}{n}\right) e^{ik\theta}, \quad (\overline{\sigma}_n a)(e^{i\theta}) := \sum_{|k|\leq n-1} a_k e^{ik\theta}.$$
14. The matrices $T_n(a)$ $(n \geq 1)$ are all banded with fixed bandwidth $2m+1$ if and only if the symbol a is a Laurent polynomial of the form $a(z) = \sum_{k=-m}^{m} a_k z^k$.
15. [RT92] (Condition numbers) Let a be a Laurent polynomial. If a does not have zeros on $\mathbb{T}$ but the winding number of a about the origin is nonzero, then the condition numbers $\kappa(T_n(a))$ grow at least exponentially to infinity, that is, there are constants $C > 0$ and $\alpha > 0$ such that $Ce^{\alpha n} \leq \kappa(T_n(a)) \leq \infty$ for all $n \geq 1$.
16. [BS99, pp. 19 and 40] (Products) If $T_n(a)$ and $T_n(b)$ are both upper-triangular or both lower-triangular, then $T_n(a)T_n(b) = T_n(ab)$. In general, the product of two Toeplitz matrices is not a Toeplitz matrix. However, if a and b are in $L^\infty(\mathbb{T})$ and at least one of the two functions belongs to $C(\mathbb{T})$, then

    $$T_n(a)T_n(b) = T_n(ab) + P_n K P_n + W_n L W_n + E_n$$

    where K and L are compact operators on l^2 and $\|E_n\| \to 0$ as $n \to \infty$. Here P_n and W_n are given by Eqs. (22.4) and (22.5).
17. [BS99, p. 42] (Asymptotics of the inverse) Let a be a function in $C(\mathbb{T})$ without zeros on $\mathbb{T}$ and with winding number zero about the origin and let n_0 be as in Fact 11(i). Then, for $n \geq n_0$,

    $$T_n(a)^{-1} = T_n(a^{-1}) + P_n K' P_n + W_n L' W_n + E'_n$$

    where K' and L' are compact operators on l^2 and $\|E'_n\| \to 0$ as $n \to \infty$.
18. [BG05, p. 35] (Tridiagonal Toeplitz matrices) Let $a(e^{i\theta}) = a_{-1}e^{-i\theta} + a_0 + a_1 e^{i\theta}$ and suppose $a_{-1} \neq 0$ and $a_1 \neq 0$. Fix any value $\alpha = \sqrt{a_{-1}/a_1}$, put $\sqrt{a_1/a_{-1}} := 1/\alpha$, and then define $\sqrt{a_1 a_{-1}} := a_1\alpha$.

    (a) The eigenvalues of $T_n(a)$ are

    $$\lambda_j = a_0 + 2\sqrt{a_1 a_{-1}} \cos\frac{\pi j}{n+1} \quad (j = 1, \ldots, n).$$

    (b) The eigenvector for λ_j (which is unique up to a scalar multiple) is

    $$\mathbf{x}_j = [x_1^{(j)}, \ldots, x_n^{(j)}]^\top \quad \text{with} \quad x_k^{(j)} = \left(\sqrt{\frac{a_1}{a_{-1}}}\right)^k \sin\frac{k\pi j}{n+1} \quad (k = 1, \ldots, n).$$

(c) The curve $a(\mathbb{T})$ is an ellipse, the eigenvalues of $T_n(a)$ all lie on the line segment between the two foci of the ellipse, and the set of the eigenvalues converges to this segment in the Hausdorff metric as n goes to infinity.

19. [TZ02] (Avram-Parter theorem) If $a \in L^1(\mathbb{T})$, then the singular values of $T_n(a)$ are asymptotically distributed as the values of $|a(e^{i\theta})|$ in the following sense. Denoting the singular values of $T_n(a)$ by $s_j(T_n(a))$ $(j = 1, \ldots, n)$, we have

$$\lim_{n\to\infty} \frac{1}{n} \sum_{j=1}^{n} f(s_j(T_n(a))) = \frac{1}{2\pi} \int_0^{2\pi} f(|a(e^{i\theta})|)\, d\theta$$

for every $f \in C^\infty(\mathbb{R})$ with compact support. If $a \in C(\mathbb{T})$, then the set of the singular values of $T_n(a)$ converges to the segment $[0, \|a\|_\infty]$ in the Hausdorff metric as $n \to \infty$.

20. [TZ02] (First Szegő limit theorem) If $a \in L^1(\mathbb{T})$ is real-valued, then the matrices $T_n(a)$ are Hermitian and their eigenvalues are asymptotically distributed as the values of $a(e^{i\theta})$. To be more precise, if we denote the eigenvalues of $T_n(a)$ by $\lambda_j(T_n(a))$ $(j = 1, \ldots, n)$, then

$$\lim_{n\to\infty} \frac{1}{n} \sum_{j=1}^{n} f(\lambda_j(T_n(a))) = \frac{1}{2\pi} \int_0^{2\pi} f(a(e^{i\theta}))\, d\theta$$

for every $f \in C^\infty(\mathbb{R})$ with compact support. If $a \in L^\infty(\mathbb{T})$ is a piecewise continuous and real-valued function, then the set of the eigenvalues of $T_n(a)$ converges to the convex hull of the essential range of a in the Hausdorff metric as $n \to \infty$.

21. [BG05, p. 274] (Schmidt-Spitzer theorem) Let $a(e^{i\theta}) = \sum_{k=-p}^{q} a_k e^{ik\theta}$ be a Laurent polynomial with $p \geq 1$, $q \geq 1$, $a_{-p}a_q \neq 0$. Given $\lambda \in \mathbb{C}$, label the $p + q$ roots $z_j(\lambda)$ of the algebraic equation $\sum_{k=-p}^{q} a_k z^{p+k} - \lambda z^p = 0$ so that $|z_1(\lambda)| \leq |z_2(\lambda)| \leq \cdots \leq |z_{p+q}(\lambda)|$. The set $\Lambda(a) := \{\lambda \in \mathbb{C} : |z_p(\lambda)| = |z_{p+1}(\lambda)|\}$ is connected and a finite union of analytic arcs, and the set of the eigenvalues of $T_n(a)$ converges to $\Lambda(a)$ in the Hausdorff metric as n goes to infinity.

22. [BS99, Chap. 3] Pseudospectra of Toeplitz matrices are much better behaved than spectra. See Section 23.2.

Examples:

1. [BS99, p. 153] If $a(z) = z$, then $T_n(a)$ and $T(a)$ are the Toeplitz matrices with ones on the subdiagonal and zeros elsewhere. The set of eigenvalues of $T_n(a)$ is the singleton $\{0\}$, whereas the spectrum of $T(a)$, that is, the set of all $\lambda \in \mathbb{C}$ for which $T(a) - \lambda I$ has no bounded inverse on l^2, is the closed unit disk in the complex plane. Thus, the spectral properties of $T_n(a)$ for $n \to \infty$ are in general in no obvious way related to those of $T_n(a)$. To understand these properties, one needs Facts 21 and 22, for example.

2. The Toeplitz matrices $A_n := [1/(j-k)]_{j,k=0}^{n-1}$ (with $1/0 := 0$) are skew-symmetric. The symbol is

$$a(e^{i\theta}) = \sum_{k\neq 0} \frac{1}{k} e^{ik\theta} = i(\pi - \theta), \quad \theta \in (0, 2\pi).$$

This is a bounded and piecewise continuous function. For the symmetric Toeplitz matrices $B_n := [1/|j-k|]_{j,k=0}^{n-1}$ (again with $1/0 := 0$), we get the symbol

$$b(e^{i\theta}) = \sum_{k\neq 0} \frac{1}{|k|} e^{ik\theta} = -\log(2 - 2\cos\theta), \quad \theta \in (0, 2\pi),$$

which is a function in $L^1(\mathbb{T}) \setminus L^\infty(\mathbb{T})$. By Fact 12, $\|A_n\| \to \pi$ and $\|B_n\| \to \infty$ as $n \to \infty$. Finally, let $\beta \in \mathbb{C} \setminus \mathbb{Z}$ and consider $A_n(\beta) := [1/(j-k-\beta)]_{j,k=0}^{n-1}$. For $\beta = \pm 1/2$, these matrices are known as the *Hilbert Toeplitz matrices.* The symbol is the bounded and piecewise continuous function

$$a_\beta(e^{i\theta}) = \frac{\pi e^{i\pi(1-\beta)}}{\sin(\pi\beta)}\, e^{i\beta\theta}, \quad \theta \in (0, 2\pi).$$

Anew by Toeplitz's theorem, $\|A_n(\beta)\| = \|T_n(a_\beta)\| \to \pi/|\sin(\pi\beta)|$ as $n \to \infty$.

3. Let the symbol $a(e^{i\theta})$ be 1 for $\theta \in (0, \pi)$ and -1 for $\theta \in (\pi, 2\pi)$. Then $T_n(a)$ is the Hermitian $n \times n$ Toeplitz matrix whose first row is

$$\frac{2}{\pi i}\left[0\,,-\frac{1}{1}\,,0\,,-\frac{1}{3}\,,0\,,-\frac{1}{5}\,,0\,\ldots\right].$$

The eigenvalues of $T_n(a)$ all lie in $(-1, 1)$. By Fact 20, the set of the eigenvalues of $T_n(a)$ converges in the Hausdorff metric to $[-1, 1]$ as $n \to \infty$. Equivalently, for every $\lambda \in [-1, 1]$ there exists a sequence $\{\lambda_1, \lambda_2, \lambda_3, \ldots\}$ such that λ_n is an eigenvalue of $T_n(a)$ and $\lambda_n \to \lambda$. On the other hand, from Fact 20 we also deduce that for each $\varepsilon \in (0, 1)$,

$$\frac{1}{n} \sum_{\lambda_j(T_n(a)) \in (-1,-1+\varepsilon]} 1 \to \frac{1}{2}, \qquad \frac{1}{n} \sum_{\lambda_j(T_n(a)) \in [1-\varepsilon,1)} 1 \to \frac{1}{2}.$$

Thus, although eventually the eigenvalues of $T_n(a)$ fill $[-1, 1]$ densely, nearly half of the eigenvalues cluster near -1 and almost half of them cluster near 1. Such behavior of eigenvalues (or singular values) is also known as *Moler's phenomenon.*

22.3 Hankel Matrices

Definitions:

An $n \times n$ **Hankel matrix** is a matrix of the form

$$H_n = [a_{i+j+1}]_{i,j=0}^{n-1} = \begin{bmatrix} a_1 & a_2 & a_3 & \cdots & a_n \\ a_2 & a_3 & a_4 & \cdots & a_{n+1} \\ a_3 & a_4 & a_5 & \cdots & a_{n+2} \\ \vdots & \vdots & \vdots & ⋰ & \vdots \\ a_n & a_{n+1} & a_{n+2} & \cdots & a_{2n-1} \end{bmatrix}. \tag{22.6}$$

Given complex numbers $(a_k)_{k=-\infty}^{\infty}$, we define two infinite Hankel matrices by

$$H := \begin{bmatrix} a_1 & a_2 & a_3 & \cdots \\ a_2 & a_3 & \cdots & \\ a_3 & \cdots & & \\ \cdots & & & \end{bmatrix}, \quad \tilde{H} := \begin{bmatrix} a_{-1} & a_{-2} & a_{-3} & \cdots \\ a_{-2} & a_{-3} & \cdots & \\ a_{-3} & \cdots & & \\ \cdots & & & \end{bmatrix}. \tag{22.7}$$

If the function $a(z) := \sum_{k=-\infty}^{\infty} a_k z^z$ is well defined for $z \in \mathbb{T}$, it is again referred to as the **symbol**. In that case, the matrices in (22.7) are written as $H(a)$ and $H(\tilde{a})$, while the matrix (22.6) is denoted by $H_n(a)$.

Clearly, the matrices $H(a)$ and $H_n(a)$ do not depend on the numbers a_k with $k \leq 0$, and if $a(z) = a_0 + a_1 z + \cdots + a_n z^n$ is a polynomial, then

$$H_n(a) = \begin{bmatrix} a_1 & a_2 & \cdots & a_n \\ a_2 & ⋰ & ⋰ & 0 \\ \vdots & ⋰ & ⋰ & \vdots \\ a_n & 0 & \cdots & 0 \end{bmatrix}.$$

In the case where $a(z) = z^n$, the matrix $H_n(a)$ has ones on the counter-diagonal and zeros elsewhere. This matrix is called the **anti-identity matrix** and we denote it by R_n.

With a polynomial $f(z) = f_0 + f_1 z + \cdots + f_n z^n$, we associate the two vectors $\mathbf{f} := [f_j]_{j=0}^n$ and $\tilde{\mathbf{f}} := [f_{n-j}]_{j=0}^n$. An $n \times n$ matrix B is called a **Hankel Bezoutian** if $R_n B$ is a Toeplitz Bezoutian.

The **companion matrix** of a polynomial $a(z) = a_0 + a_1 + \cdots + a_n z^n$ with $a_n \neq 0$ is the $n \times n$ matrix

$$C(a) := \begin{bmatrix} 0 & 0 & 0 & \dots & 0 & -a_0/a_n \\ 1 & 0 & 0 & \dots & 0 & -a_1/a_n \\ 0 & 1 & 0 & \dots & 0 & -a_2/a_n \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & -a_{n-1}/a_n \end{bmatrix}. \tag{22.8}$$

In what follows we need some basic notions from measure and integration theory. We recommend [Rud87, Chap. I and Def. 3.6] as a very readable introduction.

A set $E \subset \mathbb{R}$ is called a **Borel set** if it can be obtained from the set of all open subsets of $\mathbb{R}$ by applying at most countably many intersections, unions, or passages to complements. The set of all Borel sets is denoted by $\mathcal{B}$.

A **Borel measure** is a countably additive function $\mu : \mathcal{B} \to [0, \infty]$. Because in the literature one also encounters real-valued or complex-valued measures, we emphasize that the Borel measures considered in this chapter are supposed to be non-negative.

The **support** of a Borel measure μ is the smallest Borel set E such that $\mu(\mathbb{R} \setminus E) = 0$.

A **probability measure** is a Borel measure μ satisfying $\mu(\mathbb{R}) = 1$.

A function $f : \mathbb{R} \to \mathbb{C}$ is called $\mathcal{B}$-measurable if the preimage of every open subset of $\mathbb{C}$ is a Borel set.

We denote by $L^2(\mathbb{R}, d\mu(x))$ the usual **Lebesgue space** of all $\mathcal{B}$-measurable functions $f : \mathbb{R} \to \mathbb{C}$ for which the Lebesgue integral $\int_{\mathbb{R}} |f(x)|^2 d\mu(x)$ is finite.

Every point $p \in \mathbb{R}$ defines a point measure by the rule $\mu(E) = 1$ if $p \in E$ and $\mu(E) = 0$ if $p \notin E$. Traditionally one writes $d\mu(x) = \delta(x - p)dx$ if μ is meant to be this point measure. Accordingly, if μ is a weighted sum of point measures, one writes $d\mu(x) = \sum w_k \delta(x - p_k)dx$.

If $c : \mathbb{R} \to [0, \infty]$ is a $\mathcal{B}$-measurable function and μ is defined by $\mu(E) = \int_E c(x)dx$, one writes $d\mu(x) = c(x)dx$.

The matrix H appearing in Eq. (22.7) is said to be generated by a Borel measure measure μ on $\mathbb{R}$ if $a_k = \int_{\mathbb{R}} x^{k-1}\, d\mu(x)$ for all $k \geq 1$. In that case we denote H_n in Eq. (22.6) by $H_n[d\mu]$.

Facts:

We refer again again to [HR84], [HR10], [BS99] as background texts.

1. [HR10, p. 47] An $n \times n$ matrix B is a Hankel Bezoutian if and only if there are $\mathbf{u} = [u_j]_{j=0}^n \in \mathbb{C}^{n+1}$ and $\mathbf{v} = [v_j]_{j=0}^n \in \mathbb{C}^{n+1}$ such that
$$B = R_n \mathrm{Bez}(\mathbf{u}, \mathbf{v}) := \begin{bmatrix} u_{n-1} \dots & u_0 \\ \vdots & \iddots \\ u_0 & \end{bmatrix} \begin{bmatrix} v_n \dots & v_1 \\ \ddots & \vdots \\ & v_n \end{bmatrix} - \begin{bmatrix} v_{n-1} \dots & v_0 \\ \vdots & \iddots \\ v_0 & \end{bmatrix} \begin{bmatrix} u_n \dots & u_1 \\ \ddots & \vdots \\ & u_n \end{bmatrix}.$$
2. [HR84, pp. 22 and 36], [HR10, p. 51] An $n \times n$ matrix H_n is a Hankel matrix if and only if $H_n R_n$ is a Toeplitz matrix. Facts 22.2.7 to 22.2.10 therefore immediately yield results on the inverses of Hankel matrices. In particular, an invertible matrix is the inverse of a Hankel matrix if and only if it is a Hankel Bezoutian.
3. [HR84, p. 32] A matrix $B = [b_{ij}]_{i,j=0}^{n-1}$ is a Hankel Bezoutian if and only if there exist polynomials $g(z) = g_0 + \cdots + g_n z^n$ and $h(z) = h_0 + \cdots + h_n z^n$ such that the generating polynomial of B is $B(t, s) = (g(t)h(s) - h(t)g(s))/(t - s)$. In that case, $B = R_n \mathrm{Bez}(\tilde{\mathbf{g}}, \tilde{\mathbf{h}})$.

4. [Dym06, pp. 455–456], [HR84, p. 40], [HR10, p. 67] If $g(z) = g_0 + \cdots + g_n z^n$ and $h(z) = h_0 + \cdots + h_n z^n$ are two nonzero polynomials with $g_n \neq 0$, then
   (a) (Barnett's identity) $\text{Bez}(\mathbf{h}, \mathbf{g}) R_n = h(C(g)) H_n(g)$,
   (b) the dimension of the null space of $\text{Bez}(\tilde{\mathbf{h}}, \tilde{\mathbf{g}}) = \text{Bez}(\mathbf{g}, \mathbf{h})^\top$ is equal to the number of common zeros of the polynomials, counting multiplicities.
5. [HR88], [HR10, p. 100] If the sum of an $n \times n$ Toeplitz matrix and an $n \times n$ Hankel matrix is invertible, then the inverse is a so-called *Toeplitz-plus-Hankel Bezoutian*, that is, its generating function is of the form $\sum_{m=1}^{4} g_m(t) h_m(s)/((1 - ts)(t - s))$ with eight polynomials g_m, h_m of degree at most $n + 2$.
6. [BS99, pp. 13 and 19], [Nik02, pp. 214 and 217] The Nehari (Hartman, Kronecker) theorem says that the matrix H in Eq. (22.7) defines a bounded (compact, finite-rank) operator on l^2 if and only if there is a function a in $L^\infty(\mathbb{T})$ (in $C(\mathbb{T})$, in the rational functions without poles on $\mathbb{T}$) such that $H = H(a)$.
7. [Wid76], [BS99, p. 40] Here is a refinement of Fact 22.2.16. If $a, b \in L^\infty(\mathbb{T})$, then
$$T_n(a) T_n(b) = T_n(ab) - P_n H(a) H(\tilde{b}) P_n - W_n H(\tilde{a}) H(b) W_n,$$
where P_n and W_n are as in Eqs. (22.4) and (22.5).
8. [BO00], [BW06] Let $a \in C(\mathbb{T})$ be N times continuously differentiable ($N \geq 1$) and suppose a has no zeros on $\mathbb{T}$ and winding number zero about the origin. Let $\log a \in C(\mathbb{T})$ be any continuous logarithm of a and let $\log a(e^{i\theta}) = \sum_{k=-\infty}^{\infty} (\log a)_k e^{ik\theta}$ be the Fourier series of $\log a$. Put $G(a) := \exp(\log a)_0$,
$$a_-(e^{i\theta}) := \exp \sum_{k=1}^{\infty} (\log a)_{-k} e^{-ik\theta}, \quad a_+(e^{i\theta}) := \exp \sum_{k=0}^{\infty} (\log a)_k e^{ik\theta}.$$
Then $a = G(a) a_- a_+$. This is called the normalized *Wiener-Hopf factorization* of the function a. Let further $b := a_- a_+^{-1}$, $c := a_+ a_-^{-1}$, and let $Q_n := I - P_n$, that is, Q_n is the projection on $\ell^2(\mathbb{N})$ which sends $\{x_n\}_{n=1}^{\infty}$ to $\{0, \ldots, 0, x_{n+1}, \ldots\}$.
   (a) (Borodin-Okounkov formula) The operator $H(b) H(\tilde{c})$ is a trace class operator, the operator $I - H(b) H(\tilde{c})$ is invertible, and
$$\det T_n(a) = G(a)^n \, \frac{\det(I - Q_n H(b) H(\tilde{c}) Q_n)}{\det(I - H(b) H(\tilde{c}))} \quad \text{for all} \quad n \geq 1.$$
   (b) (Strong Szegő limit theorem) For every $\delta > 0$,
$$\det T_n(a) = G(a)^n E(a) \Big(1 + O\big(1/n^{2N-1-\delta}\big)\Big) \quad \text{as} \quad n \to \infty$$
   where $E(a) := 1/\det(I - H(b) H(\tilde{c})) = \exp \sum_{k=1}^{\infty} k (\log a)_k (\log a)_{-k}$.
9. [Nik02, p. 310] (Hamburger's theorem) Let $a_1, a_2, \ldots$ be real numbers. The Hankel matrices (22.6) are positive semidefinite for all $n \geq 1$ if and only if there is a Borel measure μ on $\mathbb{R}$ such that $H_n = H_n[d\mu]$ for all $n \geq 1$.
10. [GS58, Sect. 6.3] [Fas96] (First Szegő limit theorem for Hankel matrices) Let $d\mu(x) = w(x)\, dx$ where w is a real-valued function with support in $[-1, 1]$ which belongs to L^∞ on $[-1, 1]$. Then the eigenvalues of $H_n[d\mu]$ are asymptotically distributed as the values of $w(\cos\theta)$ for $\theta \in (0, \pi)$; that is, if we denote the eigenvalues of $H_n[d\mu]$ by $\lambda_j(H_n[d\mu])$ ($j = 1, \ldots, n$), then for every $f \in C^\infty(\mathbb{R})$ with compact support,
$$\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} f(\lambda_j(H_n[d\mu])) = \frac{1}{\pi} \int_0^\pi f(w(\cos\theta))\, d\theta.$$

11. [BCW01] Suppose $d\mu(x) = u(x)e^{-x}x^{\nu}dx$ where $\nu \geq -1/2$, u is a positive C^{∞} function on $[0, \infty)$ such that $x^n(d/dx)^m(u(x)-1)$ is bounded on $[0, \infty)$ for all integers $n, m \geq 0$, and let $u(x)$ be zero for $x < 0$. Then
$$\det H_n[d\mu] = \exp\Big(n^2 \log n + c_2 n^2 + c_3 n \log n + c_4 n + c_5\sqrt{n} + c_6 \log n + c_7 + o(1)\Big)$$
where $c_2 = -3/2$, $c_3 = \nu$, $c_4 = -\nu + \log 2\pi$, $c_6 = \nu^2 - 1/6$, and c_5, c_7 are constants which depend on u and can be explicitly computed.
12. [WW66] Let $d\mu(x) = w(x)\,dx$ with a function w which is supported in a finite segment $[a, b]$, is positive almost everywhere on $[a, b]$, and satisfies
$$\int_a^b \frac{\log w(x)}{\sqrt{(x-a)(b-x)}}\,dx > -\infty.$$
Then the smallest eigenvalue of $H_n[d\mu]$ is $\rho\sqrt{n}\,q^n(1 + o(1))$ as $n \to \infty$, where $\rho > 0$ and $0 < q < 1$ can be explicitly determined.
13. [Bec00] (Condition numbers) Hankel matrices may be very ill-conditioned. To have a precise sample result, consider the real and positive semidefinite Hankel matrices $H_n[d\mu]$. For a subset I of $\mathbb{R}$, put
$$\Gamma_n^H(I) = \inf\{\kappa(H_n[d\mu]) : \operatorname{supp}\mu \subseteq I\}.$$
Also, let $\alpha := 1 + \sqrt{2}$. Then for every $n \geq 1$,
$$\frac{\alpha^{2n-2}}{8n} \leq \Gamma_n^H([-1, 1]) \leq n\alpha^{2n-2}, \quad \frac{\alpha^{4n-4}}{8n} \leq \Gamma_n^H([0, 1]) \leq (2n-1)\alpha^{4n-4}.$$

Examples:

1. [WW66], [CL99] (More results by Szegő) If $w(x)$ is the characteristic function of $[-1, 1]$ or $[0, 1]$, then the smallest eigenvalue of $H_n[w(x)\,dx]$ is
$$2^{9/4}\pi^{3/2}\sqrt{n}(\sqrt{2}-1)^{2n+1}(1 + o(1)) \quad \text{and} \quad 2^{15/4}\pi^{3/2}\sqrt{n}(\sqrt{2}-1)^{4n}(1 + o(1)),$$
respectively. If $w(x) = e^{-x}$ with support on $[0, \infty)$ or $w(x) = e^{-x^2}$ on $\mathbb{R}$, then the smallest eigenvalue of $H_n[w(x)\,dx]$ is
$$2^{13/4}\pi^{3/2}\,n^{1/4}\exp(1-2\sqrt{2n-2})(1+o(1)) \text{ and } 2^{7/2}\pi^{3/2}\,n^{1/4}\exp(1-4\sqrt{n-1})(1+o(1)),$$
respectively.
2. The *Hilbert Hankel matrices* $H_n := [1/(j+k+1)]_{j,k=0}^{n-1}$ are $H_n[d\mu]$ with $d\mu(x) = dx$ supported on $[0, 1]$: $a_k = 1/k = \int_0^1 x^{k-1}\,dx$. According to Example 1,
$$\|H_n^{-1}\| = \frac{1}{2^{15/4}\pi^{3/2}}\,\frac{(1+\sqrt{2})^{4n}}{\sqrt{n}}\,(1 + o(1)).$$
Since $1 \leq \|H_n\| \leq \pi$, this strengthens Fact 13.

22.4 Vandermonde Matrices

Definitions:

The **Vandermonde matrix** $V(\mathbf{x})$ generated by $\mathbf{x} := [x_1, x_2, \ldots, x_n]^\top \in \mathbb{C}^n$ is the $n \times n$ matrix

$$V_n := V(\mathbf{x}) := [x_i^{j-1}]_{i,j=1}^n = \begin{bmatrix} 1 & x_1 & x_1^2 & \dots & x_1^{n-1} \\ 1 & x_2 & x_2^2 & \dots & x_2^{n-1} \\ \vdots & \vdots & \vdots & & \vdots \\ 1 & x_n & x_n^2 & \dots & x_n^{n-1} \end{bmatrix}.$$

We associate the polynomial $p(z) := \prod_{i=1}^n (z - x_i) =: p_0 + p_1 z + \ldots + z^n$ with this matrix.

Let $L_j^{\mathbf{x}}(z) = a_0^{(j)} + \cdots + a_{n-1}^{(j)} z^{n-1}$ be the jth **Lagrange interpolation polynomial** determined by the nodes $x_1, \ldots, x_n$, that is, $L_j^{\mathbf{x}}(x_j) = 1$ and $L_j^{\mathbf{x}}(x_i) = 0$ for $i \neq j$.

Facts:

1. [Pra94, p. 3] $\det V_n = \prod_{j>k}(x_j - x_k)$.
2. [Fie84] For $i = 1, \ldots, n$, put $f_i(z) := \prod_{j \neq i}(z - x_j) =: f_{i1} + f_{i2} z + \cdots + f_{in} z^{n-1}$ and denote by $W_n(\mathbf{x})$ the $n \times n$ matrix whose ith row is $[f_{i1}, f_{i2}, \ldots, f_{in}]$. Also, let $D_n(\mathbf{x}) := \operatorname{diag}[f_1(x_1), \ldots, f_n(x_n)]$. Then $V_n(\mathbf{x}) W_n(\mathbf{x})^\top = D_n(\mathbf{x})$. It follows that if $\det V_n(\mathbf{x}) \neq 0$, then the jth column of $V_n(\mathbf{x})^{-1}$ equals $[a_0^{(j)}, \ldots, a_{n-1}^{(j)}]^\top$, where the numbers $a_i^{(j)}$ are the coefficients of the Lagrange interpolation polynomial $L_j^{\mathbf{x}}(z)$.
3. [Tra66], [HR84, p. 157] (Structure of the inverse) If $\det V_n \neq 0$, then $V_n^{-1} = H_n V_n^\top D_n^{-1}$ where $D_n := \operatorname{diag}[p'(x_1), \ldots, p'(x_n)]$ and H_n is the Hankel matrix $H_n(p)$, that is,

$$H_n(p) := \begin{bmatrix} p_1 & p_2 & \dots & p_{n-1} & 1 \\ p_2 & p_3 & \dots & 1 & 0 \\ \vdots & \vdots & \iddots & \vdots & \vdots \\ p_{n-1} & 1 & \dots & 0 & 0 \\ 1 & 0 & \dots & 0 & 0 \end{bmatrix}.$$

   A generalization to the case of confluent Vandermonde matrices is in [LR04].
4. [LR04], [SA89] Vandermonde matrices diagonalize companion matrices, that is, if, in accordance with Eq. (22.8),

$$C(p) := \begin{bmatrix} 0 & 0 & 0 & \dots & 0 & -p_0 \\ 1 & 0 & 0 & \dots & 0 & -p_1 \\ 0 & 1 & 0 & \dots & 0 & -p_2 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & -p_{n-1} \end{bmatrix},$$

   then $V_n C(p) = \operatorname{diag}[x_1, \ldots, x_n]\, V_n$ or, equivalently, $C(p)^\top V_n^\top = V_n^\top \operatorname{diag}[x_1, \ldots, x_n]$. If some of the numbers $x_1, \ldots, x_n$ coincide, the Jordan canonical form of $C(p)$ can be obtained through confluent Vandermonde matrices; see [Bra64].
5. The product $V_n^* V_n$ is a (positive semidefinite) Hankel matrix.
6. [Bec00] (Condition numbers) Vandermonde matrices are notoriously ill-conditioned. Given a subset I of $\mathbb{R}$, put $\Gamma_n^V(I) := \inf\{\kappa(V(x_1, \ldots, x_n)) : x_1, \ldots, x_n \in I\}$. Then for every $n \geq 2$,

$$\frac{\eta_n}{\sqrt{n}} \leq \Gamma_n^V(\mathbb{R}) \leq \Gamma_n^V([-1,1]) \leq \eta_n n, \quad \frac{\delta_n}{\sqrt{n}} \leq \Gamma_n^V([0,\infty)) \leq \Gamma_n^V([0,1]) \leq \delta_n n$$

   where $\eta_n := \sqrt{2}(1+\sqrt{2})^{n-2}$ and $\delta_n := (1+\sqrt{2})^{2n-2} + (1+\sqrt{2})^{-(2n-2)}$.

Examples:

1. The Fourier matrix F_n given by Eq. (22.1) is $\frac{1}{\sqrt{n}}V(1, \omega_n, \ldots, \omega_n^{n-1})$.
2. In Wilkinson [Wil65, p. 372], many years before the triumphant success of computers, we already see

$$\kappa(V_{20}(1/20, 2/20, \ldots, 20/20)) \geq 2^{45}, \quad \kappa(V_{20}(1/2, 1/2^2, \ldots, 1/2^{20})) \geq 2^{171}.$$

22.5 Cauchy Matrices

Definitions:

A **Cauchy matrix** is a matrix of the form

$$C(\mathbf{a}, \mathbf{b}) := \left[\frac{1}{a_i - b_j}\right]_{i,j=1}^{n}$$

where $\mathbf{a} := [a_1, \ldots, a_n]^\top$ and $\mathbf{b} := [b_1, \ldots, b_n]^\top$ are vectors in $\mathbb{C}^n$ such that $a_j \neq b_k$ for all j, k.

Facts:

1. [Pra94, p. 3] The determinant of a Cauchy matrix is

$$\det C(\mathbf{a}, \mathbf{b}) = \frac{\prod_{j>k}(a_j - a_k)(b_k - b_j)}{\prod_{j,k}(a_j - b_k)}.$$

2. [Sch59] If $\det C(\mathbf{a}, \mathbf{b}) \neq 0$, then the i, j entry of the inverse of $C(\mathbf{a}, \mathbf{b})$ is

$$[C(\mathbf{a}, \mathbf{b})^{-1}]_{ij} = (a_j - b_i) L_j^{\mathbf{a}}(b_i) L_i^{\mathbf{b}}(a_j)$$

where $L_1^{\mathbf{a}}(x), \ldots, L_n^{\mathbf{a}}(x)$ and $L_1^{\mathbf{b}}(x), \ldots, L_n^{\mathbf{b}}(x)$ are the Lagrange interpolation polynomials associated with the nodes $\mathbf{a} = [a_1, \ldots, a_n]^\top$ and $\mathbf{b} = [b_1, \ldots, b_n]^\top$, respectively.
3. [FHR93] Let $h(z) := \prod_{j=1}^{n}(z - b_j) =: h_0 + h_1 z + \cdots + z^n$ and put

$$H_n(h) := \begin{bmatrix} h_1 & \ldots & 1 \\ \vdots & \iddots & \vdots \\ 1 & \ldots & 0 \end{bmatrix}, \quad D_n := \operatorname{diag}[h(a_1), \ldots, h(a_n)].$$

Then $D_n\, C(\mathbf{a}, \mathbf{b}) = V_n(\mathbf{a}) H_n(h) V_n(\mathbf{b})^\top$.
4. [FHR93] If $\det C(\mathbf{a}, \mathbf{b}) \neq 0$, then $C(\mathbf{a}, \mathbf{b})^{-1} = -D_{1,n}\, C(\mathbf{a}, \mathbf{b})^\top D_{2,n}$, where

$$D_{1,n} := \operatorname{diag}\left[\frac{g(b_i)}{h'(b_i)}\right]_{i=1}^{n}, \quad D_{2,n} := \operatorname{diag}\left[\frac{h(a_i)}{g'(a_i)}\right]_{i=1}^{n}$$

with $g(z) := \prod_{j=1}^{n}(z - a_j)$ and $h(z) := \prod_{j=1}^{n}(z - b_j)$.
5. [AR10], [GKO95], [Hb97], [Pan01, p. 8] Let A be an invertible $n \times n$ matrix. Suppose we have two $n \times n$ matrices M, N such that $MA - AN = \sum_{k=1}^{\nu} \mathbf{g}_k \mathbf{h}_k^\top$ with vectors $\mathbf{g}_k, \mathbf{h}_k \in \mathbb{C}^n$. Suppose further that $M = U^{-1} D(\mathbf{a}) U$ and $N = V^{-1} D(\mathbf{b}) V$, where $D(\mathbf{w}) := \operatorname{diag}[w_1, \ldots, w_n]$ for a vector $\mathbf{w} = [w_1, \ldots, w_n]^\top \in \mathbb{C}^n$. Then if $a_j \neq b_k$ for all j, k,

$$\mathcal{A} := UAV^{-1} = \sum_{k=1}^{\nu} D(U\mathbf{g}_k)C(\mathbf{a},\mathbf{b})D(V^{-\top}\mathbf{h}_k). \tag{22.9}$$

Matrices which may be represented in the form of the sum in Eq. (22.9) are said to be *Cauchy-like*. The Cauchy-like structure is preserved under Gaussian elimination with pivoting. The linear system $A\mathbf{x} = \mathbf{y}$ is equivalent to the two systems $\mathcal{A}\mathbf{z} = U\mathbf{y}$, $V\mathbf{x} = \mathbf{z}$, and a system with the Cauchy-like matrix in Eq. (22.9) may be solved fast and stably using only the data $U\mathbf{g}_k, V^{-\top}\mathbf{h}_k, \mathbf{a}, \mathbf{b}$.

Examples:

1. For $\mathbf{a} = [1,2,3]^T$ and $\mathbf{b} = [-1,0,-2]^T$,

$$C(\mathbf{a},\mathbf{b}) = \begin{bmatrix} \frac{1}{2} & 1 & \frac{1}{3} \\ \frac{1}{3} & \frac{1}{2} & \frac{1}{4} \\ \frac{1}{4} & \frac{1}{3} & \frac{1}{5} \end{bmatrix}, \quad C(\mathbf{a},\mathbf{b})^{-1} = \begin{bmatrix} -36 & 192 & -180 \\ 9 & -36 & 30 \\ 30 & -180 & 180 \end{bmatrix}$$

It is straightforward to verify Fact 2 for this matrix. For example,

$$L_1^{\mathbf{a}}(x) = \frac{x^2}{2} - \frac{5x}{2} + 3,\;\; L_1^{\mathbf{a}}(b_1) = 6,\;\; L_1^{\mathbf{b}}(x) = -x^2 - 2x,\;\; L_1^{\mathbf{b}}(a_1) = -3,\;\; a_1 - b_1 = 2,$$

and $(a_1 - b_1)L_1^{\mathbf{a}}(b_1)L_1^{\mathbf{b}}(a_1) = -36 = [C(\mathbf{a},\mathbf{b})^{-1}]_{11}$.

2. Let us check Fact 3 for $C(\mathbf{a},\mathbf{b})$ as in the previous example. We have $g(z) = (z-1)(z-2)(z-3)$ and $g'(z) = (z-2)(z-3) + (z-1)(z-3) + (z-1)(z-2)$, which gives

$$g(b_1) = -24,\;\; g(b_2) = -6,\;\; g(b_3) = -60,\;\; g'(a_1) = 2,\;\; ,g'(a_2) = -1,\;\; g'(a_3) = 2.$$

Analogously,

$$h(a_1) = 6,\;\; h(a_2) = 24, h(a_3) = 60,\;\; h'(b_1) = -1,\;\; h'(b_2) = 2,\;\; h'(b_3) = 2.$$

Therefore, $D_{1,3} = \mathrm{diag}[24,-3,-30]$ and $D_{2,3} = \mathrm{diag}[3,-24,30]$. It follows that the matrix $D_{1,3}C(\mathbf{a},\mathbf{b})^\top D_{2,3}$ is

$$\begin{bmatrix} 24 & & \\ & -3 & \\ & & -30 \end{bmatrix} \begin{bmatrix} \frac{1}{2} & \frac{1}{3} & \frac{1}{4} \\ 1 & \frac{1}{2} & \frac{1}{3} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \end{bmatrix} \begin{bmatrix} 3 & & \\ & -24 & \\ & & 30 \end{bmatrix},$$

and this is indeed minus the matrix $C(\mathbf{a},\mathbf{b})^{-1}$ of the preceding example.

22.6 Loewner Matrices

Definitions:

A matrix of the form

$$L(\mathbf{a},\mathbf{b},\mathbf{c},\mathbf{d}) := \left[\frac{c_i - d_j}{a_i - b_j}\right]_{i,j=1}^{n}$$

is called a **Loewner matrix**.[1]

Facts:

1. [Vav84] If the matrix $L(\mathbf{a},\mathbf{b},\mathbf{c},\mathbf{d})$ is invertible, then
$$L(\mathbf{a},\mathbf{b},\mathbf{c},\mathbf{d})^{-1} = D_{3,n}\, L(\mathbf{a},\mathbf{b},\mathbf{f},\mathbf{g})^\top D_{4,n}$$
with certain diagonal matrices $D_{3,n}, D_{4,n}$ and certain $\mathbf{f},\mathbf{g} \in \mathbb{C}^n$. The construction of $D_{3,n}, D_{4,n}, \mathbf{f}, \mathbf{g}$ is described in [Vav84].
2. [Fie84] The sets of all $n \times n$ Hankel matrices and of all $n \times n$ Loewner matrices $L(\mathbf{a},\mathbf{b},\mathbf{c},\mathbf{d})$ with fixed $\mathbf{a},\mathbf{b}$ are both linear spaces of the dimension $2n-1$. There is a close relation between these two spaces. Let
$$H_n := [h_{j+k+1}]_{j,k=0}^{n-1} = \begin{bmatrix} h_1 & h_2 & \dots & h_n \\ h_2 & & \iddots & \vdots \\ \vdots & \iddots & & \vdots \\ h_n & \dots & \dots & h_{2n-1} \end{bmatrix}$$
be a Hankel matrix. For $\mathbf{a},\mathbf{b} \in \mathbb{C}^n$, define $W_n(\mathbf{a})$ and $W_n(\mathbf{b})$ as in Fact 22.4.2. Then $W_n(\mathbf{a})H_nW_n(\mathbf{b}) = L(\mathbf{a},\mathbf{b},\mathbf{c},\mathbf{d})$ with $\mathbf{c}$ and $\mathbf{d}$ given by
$$\begin{bmatrix} \mathbf{c} \\ \mathbf{d} \end{bmatrix} = W_{2n}\left(\begin{bmatrix} \mathbf{a} \\ \mathbf{b} \end{bmatrix}\right) [h_1, h_2, \dots, h_{2n-1}, \xi]^\top,$$
where $\xi \in \mathbb{C}$ can be chosen arbitrarily.
3. [Loe34] [BhS09] (Loewner's theorem) Let $f : (0,\infty) \to (0,\infty)$ be a continuously differentiable function such that $\lim_{x\to 0+} f(x) = 0$. Put $f(0) := 0$. We denote by $(0,\infty)^n$ the set of all vectors $\mathbf{p} = [p_1,\dots,p_n]^\top$ with $p_j \in (0,\infty)$ $(j = 1,\dots,n)$. For $\mathbf{p} \in (0,\infty)^n$, put
$$L_n^f(\mathbf{p}) := L(\mathbf{p},\mathbf{p},f(\mathbf{p}),f(\mathbf{p})) := \left[\frac{f(p_i)-f(p_j)}{p_i-p_j}\right]_{i,j=1}^n$$
with the convention that the ii entry is $f'(p_i)$. The function f is said to be *operator monotone* on $[0,\infty)$ if $f(A) \succeq f(B)$ whenever A and B are positive semidefinite matrices satisfying $A \succeq B$; here $\succeq$ is the Loewner ordering (see Section 9.5). Loewner's theorem says that the function f is operator monotone on $[0,\infty)$ if and only if the matrices $L_n^f(\mathbf{p})$ are positive semidefinite for all $n \in \mathbb{N}$ and all $\mathbf{p} \in (0,\infty)^n$. The matrices $L_n^f(\mathbf{p})$ are in particular all positive semidefinite for $f(t) = t^r$ with $0 < r \le 1$.

Examples:

1. We consider Fact 2 for $n = 1$, that is, for $H_1 = [h_1]$, $\mathbf{a} = [a]$, $\mathbf{b} = [b]$. In that case, $W_1(\mathbf{a}) = W_1(\mathbf{b}) = [1]$ by convention. The matrix $W_2\left(\left[\begin{smallmatrix}\mathbf{a}\\ \mathbf{b}\end{smallmatrix}\right]\right)$ results from $f_1(z) = -b + z$ and $f_2(z) = -a + z$ and hence equals $\left[\begin{smallmatrix}-b & 1\\ -a & 1\end{smallmatrix}\right]$. This gives
$$\begin{bmatrix} \mathbf{c} \\ \mathbf{d} \end{bmatrix} = \begin{bmatrix} c \\ d \end{bmatrix} = \begin{bmatrix} -b & 1 \\ -a & 1 \end{bmatrix} \begin{bmatrix} h_1 \\ \xi \end{bmatrix} = \begin{bmatrix} \xi - bh_1 \\ \xi - ah_1 \end{bmatrix}.$$

---

[1] Loewner was born in Bohemia, and the original version of his name is **Löwner**.

Consequently,

$$L(\mathbf{a},\mathbf{b},\mathbf{c},\mathbf{d}) = \left[\frac{c-d}{a-b}\right] = \left[\frac{\xi - bh_1 - (\xi - ah_1)}{a-b}\right] = [h_1],$$

which indeed coincides with $W_1(\mathbf{a})H_1W_1(\mathbf{b}) = [h_1]$.

2. Let $\mathbf{q} := [q_1, \ldots, q_n]^\top$ with $q_j > 0$. Put $p_j = q_j^2$. In the special case where $f(t) = t^{1/2}$, Fact 3 then implies that the Cauchy matrices

$$C(\mathbf{q}, -\mathbf{q}) = \left[\frac{1}{q_i + q_j}\right]_{i,j=1}^n = \left[\frac{p_i^{1/2} - p_j^{1/2}}{p_i - p_j}\right]_{i,j=1}^n$$

are positive semidefinite for all $n \geq 1$. Taking $q_j = j - 1/2$, we see in particular that the Hankel matrices $[1/(i+j+1)]_{i,j=0}^{n-1}$ are all positive semidefinite. This follows also from Fact 22.3.9 and Example 22.3.2.

22.7 Jacobi Matrices

Definitions:

Real tridiagonal matrices of the form

$$\mathcal{J}_n := \begin{bmatrix} a_0 & b_0 & & & \\ c_0 & a_1 & b_1 & & \\ & c_1 & a_2 & \ddots & \\ & & \ddots & \ddots & b_{n-2} \\ & & & c_{n-2} & a_{n-1} \end{bmatrix}, \quad \mathcal{J} := \begin{bmatrix} a_0 & b_0 & & \\ c_0 & a_1 & b_1 & \\ & c_1 & a_2 & \ddots \\ & & \ddots & \ddots & \ddots \end{bmatrix}$$

are called finite and infinite **Jacobi matrices**, respectively, if $b_j c_j > 0$ for $j \geq 0$.

Facts:

1. [VK84, p. 134] Given a finite Jacobi matrix $\mathcal{J}_n$, there exists an invertible diagonal matrix D_n such that $D_n \mathcal{J}_n D_n^{-1}$ is a symmetric Jacobi matrix with positive subdiagonal and superdiagonal entries.
2. [VK84, p. 135] The eigenvalues of a finite Jacobi matrix are real and simple.
3. [GK02, Chap. II] [VBM07, Vol. I, p. 42] (Gantmacher and Krein's theorem) An invertible symmetric matrix $S_n = [s_{ij}]_{i,j=1}^n$ is the inverse of an invertible symmetric finite Jacobi matrix if and only if there are $u_1, \ldots, u_n, v_1, \ldots, v_n \in \mathbb{R}$ such that $s_{ij} = u_i v_j$ for $i \leq j$.
4. Finite Jacobi matrices of the form

$$\mathcal{H}_n := \begin{bmatrix} a_0 & -1 & & & \\ -1 & a_1 & -1 & & \\ & -1 & a_2 & \ddots & \\ & & \ddots & \ddots & -1 \\ & & & -1 & a_{n-1} \end{bmatrix} = T_n(\sigma) + \mathrm{diag}[a_0, \ldots, a_{n-1}]$$

are called *discrete Hamiltonians.* Here $\sigma(z) = -z - z^{-1}$. For $z = e^{i\theta}$ on the unit circle, we get $\sigma(z) = -2\cos\theta$.

(a) [Special case of Fact 22.2.18] The Toeplitz matrix $T_n(\sigma)$ is one version of a so-called *discrete Laplacian.* Its eigenvalues are $\lambda_j = -2\cos(\pi j/(n+1))$, $j = 1, \ldots, n$.

(b) [BG05, Sec. 14], [TE05, Chap. 36] The presence of the so-called *discrete potential* $\operatorname{diag}[a_0, \ldots, a_{n-1}]$ may yield eigenvalues outside the segment $[-2, 2]$. If exactly one of the numbers $a_0, \ldots, a_{n-1}$ is nonzero and λ is an eigenvalue of $\mathcal{H}_n$, then the corresponding eigenvector is extended for $|\lambda| < 2$ and localized for $|\lambda| > 2$; see [BG05, p. 339] for the result and the pertinent definitions. That the same phenomenon happens for general potentials is the problem of *Anderson localization.*

(c) [VK84, p. 141] If all principal minors of $\mathcal{H}_n$ are nonzero, then $\mathcal{H}_n = L_n D_n L_n^\top$ where, with $\beta_1 := 1/a_0$ and $\beta_i := 1/(a_{i-1} - \beta_{i-1})$ for $i = 2, \ldots, n$, the matrices D_N and L_N are given by

$$D_n := \operatorname{diag}[1/\beta_1, \ldots, 1/\beta_n], \quad L_n := \begin{bmatrix} 1 & & & \\ -\beta_1 & 1 & & \\ & \ddots & \ddots & \\ & & -\beta_{n-1} & 1 \end{bmatrix}.$$

5. [Dei99, p. 14] The infinite symmetric Jacobi matrix

$$\mathcal{J} := \begin{bmatrix} a_0 & b_0 & & \\ b_0 & a_1 & b_1 & \\ & b_1 & a_2 & \ddots \\ & & \ddots & \ddots & \ddots \end{bmatrix}, \quad b_j > 0 \tag{22.10}$$

defines a bounded operator on l^2 if and only if the sequences (a_n) and (b_n) are bounded.

6. [Dei99, pp. 14–19] Let $\mathcal{J}$ be the infinite matrix (22.10) and suppose $\mathcal{J}$ generates a bounded operator on l^2. Then $\mathcal{J} - \lambda I$ has a bounded inverse on l^2 for $\lambda \in \mathbb{C} \setminus \mathbb{R}$ and there exists a unique Borel probability measure μ with compact support on $\mathbb{R}$ such that the $0, 0$ entry of the matrix $(\mathcal{J} - \lambda I)^{-1}$ is given by

$$[(\mathcal{J} - \lambda I)^{-1}]_{00} = \int_{\mathbb{R}} \frac{d\mu(x)}{x - \lambda} \quad (\lambda \in \mathbb{C} \setminus \mathbb{R}).$$

The measure μ is called the *spectral measure* of $\mathcal{J}$. The operator induced by $\mathcal{J}$ on l^2 is unitarily similar to the operator of multiplication by x on $L^2(\mathbb{R}, d\mu(x))$.

7. [Dei99, pp. 14–19] Let μ be a Borel probability measure with compact support on $\mathbb{R}$ and suppose the support of μ is not a finite set. Let $p_0(x), p_1(x), p_2(x), \ldots$ denote the normalized orthogonal polynomials in $L^2(\mathbb{R}, d\mu(x))$ with positive leading coefficient. For $k \geq 0$, put

$$a_k := \int_{\mathbb{R}} x p_k^2(x)\, d\mu(x), \quad b_k := \int_{\mathbb{R}} x p_{k+1}(x) p_k(x)\, d\mu(x).$$

Then we have the recursion formulas $xp_0(x) = b_0 p_1(x) + a_0 p_0(x)$ and

$$xp_k(x) = b_k p_{k+1}(x) + a_k p_k(x) + b_{k-1} p_{k-1}(x) \quad (k \geq 1).$$

The matrix (22.10) formed with these a_k and b_k has the spectral measure μ.

8. [Dei99, pp. 23–24] Let $\mathcal{J}_n$ be the finite symmetric Jacobi matrix

$$\mathcal{J}_n := \begin{bmatrix} a_0 & b_0 & & & \\ b_0 & a_1 & b_1 & & \\ & b_1 & a_2 & \ddots & \\ & & \ddots & \ddots & b_{n-2} \\ & & & b_{n-2} & a_{n-1} \end{bmatrix}, \quad b_j > 0. \tag{22.11}$$

Let Λ_n be the diagonal matrix of the eigenvalues of $\mathcal{J}_n$ and let $U_n = [u_{jk}]_{j,k=0}^{n-1}$ be the associated orthogonal matrix of eigenvectors, so that the equality $\mathcal{J}_n U_n = U_n \Lambda_n$ holds. Then $u_{0k} \neq 0$ for $k = 0, \ldots, n-1$ and

$$[(\mathcal{J}_n - \lambda I)^{-1}]_{00} = \sum_{k=0}^{n-1} \frac{u_{0k}^2}{\lambda_k - \lambda} = \int_{\mathbb{R}} \frac{d\mu(x)}{x - \lambda} \quad (\lambda \in \mathbb{C} \setminus \{\lambda_1, \ldots, \lambda_n\})$$

with the measure $d\mu(x) := \sum_{k=0}^{n-1} u_{0k}^2 \delta(x - \lambda_k) dx$, which is referred to as the *spectral measure* of the finite Jacobi matrix (22.11). Conversely, given a probability measure $d\mu(x) := \sum_{k=0}^{n-1} \mu_k \delta(x - \lambda_k) dx$ with distinct λ_k and $\mu_k > 0$ for all k, let $p_0(x), p_1(x), \ldots, p_{n-1}(x)$ be the normalized orthogonal polynomials in $L^2(\mathbb{R}, d\mu(x))$ with positive leading coefficient and define the numbers a_k ($k = 0, \ldots, n-1$) and b_k ($k = 0, \ldots, n-2$) as in Fact 7. Then the analogues of the recursion formulas of that fact hold. The spectral measure of the matrix (22.11) built with these a_k and b_k is exactly μ.
9. [Dei99, pp. 52–56] The roots of the orthogonal polynomial $p_k(x)$ constructed in Fact 7 coincide with the eigenvalues of the matrix $\mathcal{J}_k$ defined by (22.11) for every $k \geq 1$, and the roots of the orthogonal polynomial $p_k(x)$ constructed in Fact 8 are the eigenvalues of the matrix $\mathcal{J}_k$ defined by Eq. (22.11) for every $1 \leq k \leq n-1$.

Examples:

1. Consider the matrices

$$\mathcal{J}_3 = \begin{bmatrix} 1 & 2 & 0 \\ 2 & 3 & 1 \\ 0 & 1 & 1 \end{bmatrix}, \quad \mathcal{J}_3^{-1} = \begin{bmatrix} -1 & 1 & -1 \\ 1 & -\frac{1}{2} & \frac{1}{2} \\ -1 & \frac{1}{2} & \frac{1}{2} \end{bmatrix}.$$

Clearly, $\mathcal{J}_3$ is a Jacobi matrix, and letting $\mathcal{J}_3^{-1} =: [s_{ij}]_{i,j=1}^3$, we have $s_{ij} = u_i v_j$ for $i \leq j$ with $[u_1, u_2, u_3] = [1, -\frac{1}{2}, -\frac{1}{2}]$ and $[v_1, v_2, v_3] = [-1, 1, -1]$.
2. Let $\mathcal{J}$ be the infinite Jacobi matrix (22.10) with $a_j = 0$ and $b_j = 1$. If $\lambda = iy$ with $y > 0$, then

$$[(\mathcal{J} - iyI)^{-1}]_{00} = i\left(\frac{\sqrt{y^2+4}}{2} - \frac{y}{2}\right). \tag{22.12}$$

Indeed, the infinite system $(\mathcal{J} - iyI)[\xi_0, \xi_1, \ldots]^\top = [1, 0, \ldots]^\top$ is equivalent to the equations

$$-iy\xi_0 + \xi_1 = 1, \quad \xi_{n+2} - iy\xi_{n+1} + \xi_n = 0 \ (n \geq 0),$$

and the difference equation yields $\xi_n = Aq_-^n + Bq_+^n$ with $q_\pm := i(y/2 \pm \sqrt{y^2+4}/2)$. Since $|q_+| > 1$, it follows that $\xi_n = Aq_-^n$, and the first equation $-iy\xi_0 + \xi_1 = 1$ finally gives

$A = 1/(q_- - iy) = -q_-$, whence $\xi_0 = -q_-$. Taking into account that the right-hand side of Eq. (22.12) is

$$\frac{iy}{2\pi}\int_{-2}^{2}\frac{\sqrt{4-x^2}}{x^2+y^2}\,dx = \frac{1}{2\pi}\int_{-2}^{2}\frac{\sqrt{4-x^2}\,(x+iy)}{x^2+y^2}\,dx = \frac{1}{2\pi}\int_{-2}^{2}\frac{\sqrt{4-x^2}}{x-iy}\,dx,$$

we see that the spectral measure is $d\mu(x) = (2\pi)^{-1}\sqrt{4-x^2}\,dx$, $x \in [-2,2]$. The corresponding orthogonal polynomials are $p_k(x) = U_k(x/2)$ where U_k is the kth Chebyshev polynomial of the second kind, $U_k(\cos\theta) := \sin((k+1)\theta)/\sin\theta$.

3. Let $n = 3$ and $\mathcal{J}_3$ be the matrix (22.11) with $a_j = 0$ and $b_j = 1$. In that case

$$[(\mathcal{J}_3 - \lambda I)^{-1}]_{00} = \frac{1-\lambda^2}{2\lambda-\lambda^3} = \frac{1}{2}\,\frac{1}{0-\lambda} + \frac{1}{4}\,\frac{1}{\sqrt{2}-\lambda} + \frac{1}{4}\,\frac{1}{-\sqrt{2}-\lambda},$$

which implies that the spectral measure is

$$d\mu(x) = \frac{1}{2}\delta(x)\,dx + \frac{1}{4}\delta(x-\sqrt{2})\,dx + \frac{1}{4}\delta(x+\sqrt{2})\,dx.$$

The associate orthogonal polynomials $p_k(x)$ ($k = 0,1,2$) are $U_k(x/2)$ as in the previous example; that is, $p_0(x) = 1$, $p_1(x) = x$, $p_2(x) = x^2 - 1$.

22.8 There is More

As already said, the above is an extremely narrow selection of what is known about matrices of special types. Many types of structured matrices, including Toeplitz, Hankel, Vandermonde, and Cauchy matrices, can be treated by employing the happy circumstance that they have small displacement rank. See, for example, Chapter 62 and the books [HR84], [BP94], [Pan01]. We could only touch lightly the business of semiseparable matrices (Fact 22.7.3) and refer to the thesis [Van04] and the two books [VBM07] for more. Quasiseparable matrices are generalizations of semiseparable matrices and another hot topic of present-day research. See, for example, [BEG08]. Finally, a good deal of recent research is devoted to the block cases and the multivariate (= higher-dimensional) versions of the types of matrices we exhibited.

Acknowledgment

We thank Percy Deift and Karla Rost for reading parts of this chapter and making a series of useful comments.

References 23-17

Eigenvalues often provide great insight into the behavior of matrices, precisely explaining, for example, the *asymptotic* character of functions of matrices like A^k and e^{tA}. Yet many important applications produce matrices whose behavior cannot be explained by eigenvalues alone. In such circumstances further information can be gleaned from broader sets in the complex plane, such as the numerical range (see Chapter 25), the polynomial numerical hull [Nev93], [Gre02], and the subject of this chapter, pseudospectra.

The ε-pseudospectrum of a square matrix is a subset of the complex plane that always includes the spectrum, but can potentially contain points far from any eigenvalue. Unlike the spectrum, pseudospectra vary with choice of norm and, thus, for a given application one must take care to work in a physically appropriate norm. Unless otherwise noted, throughout this chapter we assume that $A \in \mathbb{C}^{n\times n}$ is a square matrix with complex entries, and that $\|\cdot\|$ denotes a vector space norm and the matrix norm it induces. When speaking of a norm associated with an inner product, we presume that adjoints and normal and unitary matrices are defined with respect to that inner product. All computational examples given here use the 2-norm.

For further details about theoretical aspects of this subject and the application of pseudospectra to a variety of problems, see [TE05]; for applications in control theory, see [HP05]; and for applications in perturbation theory, see [CCF96].

23.1 Fundamentals of Pseudospectra

Definitions:

The **ε-pseudospectrum** of a matrix $A \in \mathbb{C}^{n\times n}$, $\varepsilon > 0$, is the set

$$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : z \in \sigma(A+E) \text{ for some } E \in \mathbb{C}^{n\times n} \text{ with } \|E\| < \varepsilon\}.$$

(This definition is sometimes written with a weak inequality, $\|E\| \le \varepsilon$; for matrices the difference has little significance, but the strict inequality proves to be convenient for infinite-dimensional operators. See [Sha09] for a thorough discussion of these subtleties.)

If $\|A\mathbf{v} - z\mathbf{v}\| < \varepsilon\|\mathbf{v}\|$ for some $\mathbf{v} \neq 0$, then z is an **ε-pseudoeigenvalue** of A with corresponding **ε-pseudoeigenvector $\mathbf{v}$**.

For $A \in \mathbb{C}^{n\times n}$ and $z \notin \sigma(A)$, the **resolvent** of A at z is the matrix $(zI - A)^{-1}$.

Facts: [TE05]

1. Equivalent definitions. The set $\sigma_\varepsilon(A)$ can be equivalently defined as follows.
   (a) The subset of the complex plane bounded within the $1/\varepsilon$ level set of the norm of the resolvent:
   $$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : \|(zI - A)^{-1}\| > \varepsilon^{-1}\}, \tag{23.1}$$
   with the convention that $\|(zI - A)^{-1}\| = \infty$ when $zI - A$ is not invertible, i.e., when $z \in \sigma(A)$.
   (b) The set of all ε-pseudoeigenvalues of A:
   $$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : \|A\mathbf{v} - z\mathbf{v}\| < \varepsilon \text{ for some unit vector } \mathbf{v} \in \mathbb{C}^n\}.$$
2. For finite $\varepsilon > 0$, $\sigma_\varepsilon(A)$ is a bounded open set in $\mathbb{C}$ containing no more than n connected components, and $\sigma(A) \subset \sigma_\varepsilon(A)$. Each connected component must contain at least one eigenvalue of A.
3. Pseudospectral mapping theorems.
   (a) For any $\alpha, \gamma \in \mathbb{C}$ with $\gamma \neq 0$, $\quad \sigma_\varepsilon(\alpha I + \gamma A) = \alpha + \sigma_{\varepsilon/\gamma}(A)$.
   (b) [Lui03] Suppose f is a function analytic on $\sigma_\varepsilon(A)$ for some $\varepsilon > 0$, and define $\gamma(\varepsilon) = \sup_{\|E\| \leq \varepsilon} \|f(A + E) - f(A)\|$. Then $f(\sigma_\varepsilon(A)) \subseteq \sigma_{\gamma(\varepsilon)}(f(A))$. See [Lui03] for several more inclusions of this type.
4. Stability of pseudospectra. For any $\varepsilon > 0$ and E such that $\|E\| < \varepsilon$,
   $$\sigma_{\varepsilon - \|E\|}(A) \;\subseteq\; \sigma_\varepsilon(A + E) \;\subseteq\; \sigma_{\varepsilon + \|E\|}(A).$$
5. Properties of pseudospectra as $\varepsilon \to 0$.
   (a) If λ is a eigenvalue of A with index k, then there exist constants d and C such that $\|(zI - A)^{-1}\| \leq C|z - \lambda|^{-k}$ for all z such that $|z - \lambda| < d$.
   (b) Any two matrices with the same ε-pseudospectra for all $\varepsilon > 0$ have the same minimal polynomial.
6. Suppose $\|\cdot\|$ is the natural norm in an inner product space.
   (a) The matrix A is normal (see Section 8.2) if and only if $\sigma_\varepsilon(A)$ equals the union of open ε-balls about each eigenvalue for all $\varepsilon > 0$.
   (b) For any $A \in \mathbb{C}^{n \times n}$, $\sigma_\varepsilon(A^*) = \overline{\sigma_\varepsilon(A)}$.
7. [BLO03] Suppose $\|\cdot\|$ is the natural norm in an inner product space. The point $z = x + \mathrm{i}y$, $x, y \in \mathbb{R}$, is on the boundary of $\sigma_\varepsilon(A)$ provided $\mathrm{i}y$ is an eigenvalue of the Hamiltonian matrix
   $$\begin{bmatrix} xI - A^* & \varepsilon I \\ -\varepsilon I & A - xI \end{bmatrix}.$$
   This fact implies that the boundary of $\sigma_\varepsilon(A)$ cannot contain a segment of any vertical line or, substituting $e^{\mathrm{i}\theta}A$ for A, a segment of any straight line.
8. The following results provide lower and upper bounds on the ε-pseudospectrum; Δ_δ denotes the open unit ball of radius δ in $\mathbb{C}$, and $\kappa(X) = \|X\|\|X^{-1}\|$.
   (a) For all $\varepsilon > 0$, $\sigma(A) + \Delta_\varepsilon \subseteq \sigma_\varepsilon(A)$.
   (b) For any nonsingular $S \in \mathbb{C}^{n \times n}$ and all $\varepsilon > 0$,
   $$\sigma_{\varepsilon/\kappa(S)}(SAS^{-1}) \;\subseteq\; \sigma_\varepsilon(A) \;\subseteq\; \sigma_{\varepsilon\kappa(S)}(SAS^{-1}).$$

(c) (Bauer–Fike Theorems [BF60], [Dem97]) Let $\|\cdot\|$ denote a monotone norm. If A is diagonalizable, $A = V\Lambda V^{-1}$, then for all $\varepsilon > 0$,

$$\sigma_\varepsilon(A) \subseteq \sigma(A) + \Delta_{\varepsilon\kappa(V)}.$$

If $A \in \mathbb{C}^{n\times n}$ has n distinct eigenvalues $\lambda_1, \ldots, \lambda_n$, then for all $\varepsilon > 0$,

$$\sigma_\varepsilon(A) \subseteq \cup_{j=1}^{N}(\lambda_j + \Delta_{\varepsilon n\kappa(\lambda_j)}),$$

where $\kappa(\lambda_j)$ here denotes the eigenvalue condition number of λ_j (i.e., $\kappa(\lambda_j) = 1/|\widehat{\mathbf{v}}_j^*\mathbf{v}_j|$, where $\widehat{\mathbf{v}}_j$ and $\mathbf{v}_j$ are unit-length left and right eigenvectors of A corresponding to the eigenvalue λ_j).

(d) If $\|\cdot\|$ is the natural norm in an inner product space, then for any $\varepsilon > 0$, $\sigma_\varepsilon(A) \subseteq W(A) + \Delta_\varepsilon$, where $W(\cdot)$ denotes the numerical range (Chapter 25).

(e) If $\|\cdot\|$ is the natural norm in an inner product space and U is a unitary matrix, then $\sigma_\varepsilon(U^*AU) = \sigma_\varepsilon(A)$ for all $\varepsilon > 0$.

(f) If $\|\cdot\|$ is unitarily invariant, then $\sigma_\varepsilon(A) \subseteq \sigma(A) + \Delta_{\varepsilon+\mathrm{dep}(A)}$, where $\mathrm{dep}(\cdot)$ denotes Henrici's departure from normality (i.e., the norm of the off-diagonal part of the triangular factor in a Schur decomposition, minimized over all such decompositions).

(g) (Geršgorin Theorem for pseudospectra [ET01]) Using the induced matrix 2-norm, for any $\varepsilon > 0$,

$$\sigma_\varepsilon(A) \subseteq \cup_{j=1}^{n}(a_{jj} + \Delta_{r_j+\varepsilon\sqrt{n}}),$$

where $r_j = \sum_{k=1,k\neq j}^{n} |a_{jk}|$.

9. The following results bound $\sigma_\varepsilon(A)$ by pseudospectra of smaller matrices. Here $\|\cdot\|$ is the natural norm in an inner product space.

(a) [GL02] If A has the block form

$$A = \begin{bmatrix} B & C \\ D & E \end{bmatrix},$$

then

$$\sigma_\varepsilon(A) \ \subseteq\ \sigma_\delta(B) \cup \sigma_\delta(E),$$

where $\delta = (\varepsilon + \|D\|)\sqrt{1 + \|C\|/(\varepsilon + \|D\|)}$. Provided $\varepsilon > \|D\|$,

$$\sigma_\gamma(B) \cup \sigma_\gamma(E) \ \subseteq\ \sigma_\varepsilon(A),$$

where $\gamma = \varepsilon - \|D\|$.

(b) If the columns of $V \in \mathbb{C}^{n\times m}$ form a basis for an invariant subspace of A, and $\widehat{V} \in \mathbb{C}^{n\times m}$ is such that $\widehat{V}^*V = I$, then $\sigma_\varepsilon(\widehat{V}^*AV) \subseteq \sigma_\varepsilon(A)$. In particular, if the columns of U form an orthonormal basis for an invariant subspace of A, then $\sigma_\varepsilon(U^*AU) \subseteq \sigma_\varepsilon(A)$.

(c) [ET01] If $U \in \mathbb{C}^{n\times m}$ has orthonormal columns and $AU = UH + R$, then $\sigma(H) \subseteq \sigma_\varepsilon(A)$ for $\varepsilon = \|R\|$.

(d) (Arnoldi factorization) If $AU = [U\ \mathbf{u}]H$, where $H \in \mathbb{C}^{(m+1)\times m}$ is an upper Hessenberg matrix ($h_{jk} = 0$ if $j > k+1$) and the columns of $[U\ \mathbf{u}] \in \mathbb{C}^{n\times(m+1)}$ are orthonormal, then $\sigma_\varepsilon(H) \subseteq \sigma_\varepsilon(A)$. (The ε-pseudospectrum of a rectangular matrix is defined in Section 23.5.)

10. [LP08] The Lipschitz continuity of the pseudospectrum has been studied in detail, with identification of certain "resolvent critical" $z \in \mathbb{C}$ (including those points where components of the pseudospectra coalesce as ε increases) that can compromise continuity.

Examples:

The plots of pseudospectra that follow show the boundary of $\sigma_\varepsilon(A)$ for various values of ε, with the smallest values of ε corresponding to those boundaries closest to the eigenvalues. In all cases, $\|\cdot\|$ is the 2-norm.

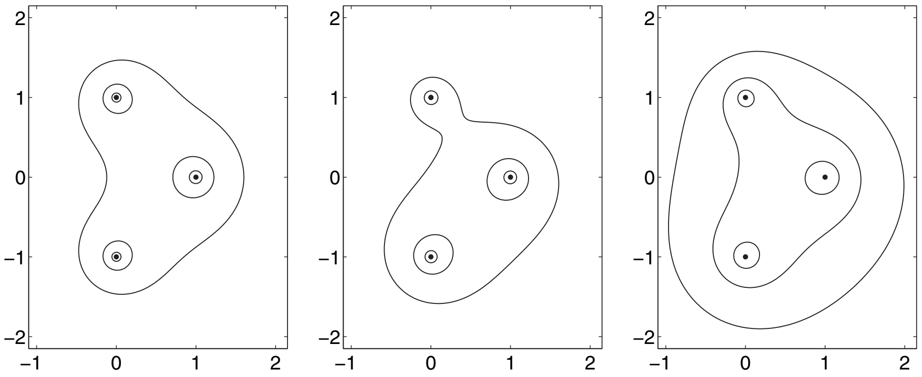

FIGURE 23.1 Spectra (solid dots) and ε-pseudospectra of the three matrices of Example 1, each with $\sigma(A) = \{1, \mathrm{i}, -\mathrm{i}\}$; $\varepsilon = 10^{-1}$, $10^{-1.5}$, 10^{-2}.

1. The following three matrices all have the same eigenvalues, $\sigma(A) = \{1, \pm\mathrm{i}\}$, yet their pseudospectra, shown in Figure 23.1, differ considerably:

$$\begin{bmatrix} 0 & -1 & 10 \\ 1 & 0 & 5 \\ 0 & 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} 0 & -1 & 10 \\ 1 & 0 & 5\mathrm{i} \\ 0 & 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} 2 & -5 & 10 \\ 1 & -2 & 5\mathrm{i} \\ 0 & 0 & 1 \end{bmatrix}.$$

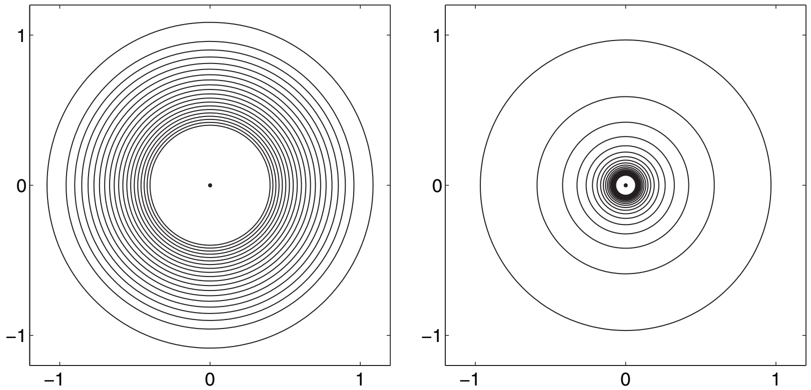

FIGURE 23.2 Spectra (solid dots) and ε-pseudospectra of the matrices in Example 2 for $\varepsilon = 10^{-1}$, $10^{-2}, \ldots, 10^{-20}$.

2. [RT92] For any matrix that is zero everywhere except the first superdiagonal, $\sigma_\varepsilon(A)$ consists of an open disk centered at zero whose radius depends on ε for all $\varepsilon > 0$. Figure 23.2 shows pseudospectra for two such examples of dimension $n = 50$:

$$\begin{bmatrix} 0 & 1 & & & \\ & 0 & 1 & & \\ & & \ddots & \ddots & \\ & & & 0 & 1 \\ & & & & 0 \end{bmatrix}, \quad \begin{bmatrix} 0 & 3 & & & \\ & 0 & 3/2 & & \\ & & \ddots & \ddots & \\ & & & 0 & 3/(n-1) \\ & & & & 0 \end{bmatrix}.$$

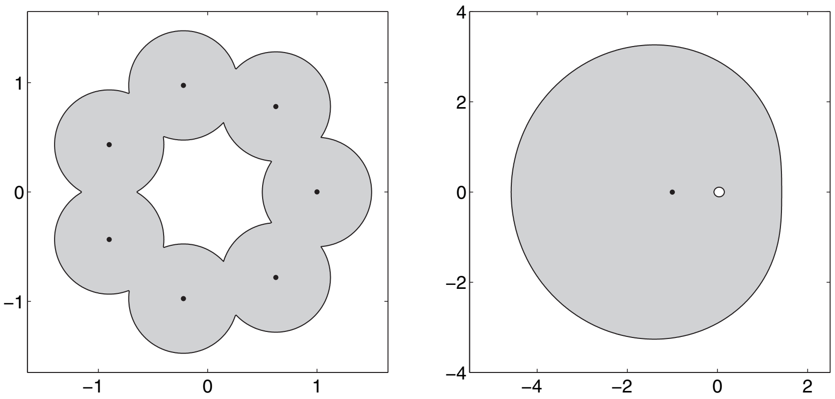

FIGURE 23.3 Spectra (solid dots) and ε-pseudospectra (gray regions) of the matrices in Example 3 for $\varepsilon = .5$ (left) and $\varepsilon = 10^{-3}$ (right). Both plotted pseudospectra are doubly connected.

Though these matrices have the same minimal polynomial, the pseudospectra differ considerably.

3. It is evident from Figure 23.1 that the components of $\sigma_\varepsilon(A)$ need not be convex. In fact, they need not be simply connected; that is, $\sigma_\varepsilon(A)$ can have "holes." This is illustrated in Figure 23.3 for the following examples, a circulant (hence, normal) matrix and a defective matrix constructed by Demmel [Dem87]:

$$\begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \qquad \begin{bmatrix} -1 & -100 & -10000 \\ 0 & -1 & -100 \\ 0 & 0 & -1 \end{bmatrix}.$$

23.2 Toeplitz Matrices

Given the rich variety of important applications in which Toeplitz matrices arise, we are fortunate that so much is now understood about their spectral properties. Nonnormal Toeplitz matrices are prominent examples of matrices whose eigenvalues provide only limited insight into system behavior. The spectra of infinite-dimensional Toeplitz matrices are easily characterized, and one would hope to use these results to approximate the spectra of more recalcitrant large, finite-dimensional examples. For generic problems, the spectra of finite-dimensional Toeplitz matrices do not converge to the spectrum of the corresponding infinite-dimensional Toeplitz operator. However, the ε-pseudospectra do converge in the $n \to \infty$ limit for all $\varepsilon > 0$, and, moreover, for banded Toeplitz matrices this convergence is especially striking as the resolvent grows exponentially with n in certain regions. Comprehensive references addressing the pseudospectra of Toeplitz matrices include the books [BS99] and [BG05]. For a generalization of these results to "twisted Toeplitz matrices," where the entries on each diagonal are samples of a smoothly varying function, see [TC04].

Definitions:

A **Toeplitz operator** is a singly infinite matrix with constant entries on each diagonal:

$$T = \begin{bmatrix} a_0 & a_{-1} & a_{-2} & a_{-3} & \cdots \\ a_1 & a_0 & a_{-1} & a_{-2} & \ddots \\ a_2 & a_1 & a_0 & a_{-1} & \ddots \\ a_3 & a_2 & a_1 & a_0 & \ddots \\ \vdots & \ddots & \ddots & \ddots & \ddots \end{bmatrix}$$

for $a_0, a_{\pm 1}, a_{\pm 2}, \ldots \in \mathbb{C}$.

Provided it is well defined for all z on the unit circle $\mathbb{T}$ in the complex plane, the function $a(z) = \sum_{k=-\infty}^{\infty} a_k z^k$ is called the **symbol** of T.

The set $a(\mathbb{T}) \subset \mathbb{C}$ is called the **symbol curve**.

Given a symbol a, the corresponding n-dimensional **Toeplitz matrix** takes the form

$$T_n = \begin{bmatrix} a_0 & a_{-1} & a_{-2} & \cdots & a_{1-n} \\ a_1 & a_0 & a_{-1} & \ddots & \vdots \\ a_2 & a_1 & a_0 & \ddots & a_{-2} \\ \vdots & \ddots & \ddots & \ddots & a_{-1} \\ a_{n-1} & \cdots & a_2 & a_1 & a_0 \end{bmatrix} \in \mathbb{C}^{n \times n}.$$

For a symbol $a(z) = \sum_{k=-\infty}^{\infty} a_k z^k$, the set $\{T_n\}_{n \geq 1}$ is called a **family of Toeplitz matrices**.

A family of Toeplitz matrices with symbol a is **banded** if there exists some $m \geq 0$ such that $a_{\pm k} = 0$ for all $k \geq m$.

Facts:

1. [Böt94] (Convergence of pseudospectra) Let $\|\cdot\|$ denote any p norm. If the symbol a is a continuous function on $\mathbb{T}$, then for all $\varepsilon > 0$,

$$\lim_{n \to \infty} \sigma_\varepsilon(T_n) \to \sigma_\varepsilon(T)$$

as $n \to \infty$, where T is the infinite-dimensional Toeplitz operator with symbol a acting on the space ℓ_p, and its ε-pseudospectrum is a natural generalization of the first definition in Section 23.1. The convergence of sets is understood in the Hausdorff sense [Hau91, p. 167], i.e., the distance between bounded sets $\Sigma_1, \Sigma_2 \subseteq \mathbb{C}$ is given by

$$d(\Sigma_1, \Sigma_2) = \max\left\{ \sup_{s_1 \in \Sigma_1} \inf_{s_2 \in \Sigma_2} |s_1 - s_2|, \quad \sup_{s_2 \in \Sigma_2} \inf_{s_1 \in \Sigma_1} |s_2 - s_1| \right\}.$$

2. [BS99] Provided the symbol a is a continuous function on $\mathbb{T}$, the spectrum $\sigma(T)$ of the infinite dimensional Toeplitz operator T on ℓ_p comprises $a(\mathbb{T})$ together with all points $z \in \mathbb{C} \setminus a(\mathbb{T})$ that $a(\mathbb{T})$ encloses with winding number

$$\frac{1}{2\pi \mathrm{i}} \int_{a(\mathbb{T})} \frac{1}{\zeta - z} \, d\zeta$$

nonzero. From the previous fact, we deduce that $\|(zI - T_n)^{-1}\| \to \infty$ as $n \to \infty$ if $z \in \sigma(T)$ and that, for any fixed $\varepsilon > 0$, there exists some $N \geq 1$ such that $\sigma(T) \subseteq \sigma_\varepsilon(T_n)$ for all $n \geq N$.

3. [RT92] (Exponential growth of the resolvent) If the family of Toeplitz matrices T_n is banded, then for any fixed $z \in \mathbb{C}$ such that the winding number of $a(\mathbb{T})$ with respect to z is nonzero, there exists some $\gamma > 1$ and $N \geq 1$ such that $\|(zI - T_n)^{-1}\| \geq \gamma^n$ for all $n \geq N$.

Examples:

1. Consider the family of Toeplitz matrices with symbol

$$a(t) = t - \tfrac{1}{2} - \tfrac{1}{16}t^{-1}.$$

For any dimension n, the spectrum $\sigma(T_n(a))$ is contained in the line segment $[-\frac{1}{2} - \frac{1}{2}\,\mathrm{i}, -\frac{1}{2} + \frac{1}{2}\,\mathrm{i}]$ in the complex plane. This symbol was selected so that $\sigma(A)$ falls in both the left half-plane and the unit disk, while even for relatively small values of ε, $\sigma_\varepsilon(A)$ contains both points in the right half-plane and points outside the unit disk for all but the smallest values of n; see Figure 23.4 for $n = 50$.

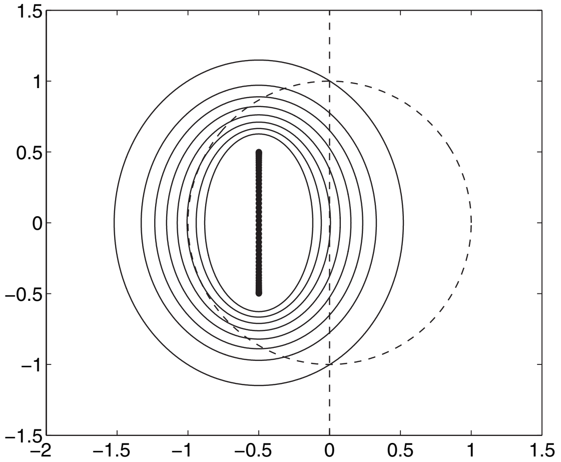

FIGURE 23.4 Spectrum (solid dots, so close they appear to be a thick line segment with real part $-1/2$) and ε-pseudospectra of the Toeplitz matrix T_{50} from Example 1; $\varepsilon = 10^{-1}, 10^{-3}, \ldots, 10^{-15}$. The dashed lines show the unit circle and the imaginary axis.

2. Pseudospectra of matrices with the symbols

$$a(t) = \mathrm{i}t^4 + t^2 + 2t + 5t^{-2} + \mathrm{i}t^{-5}$$

and

$$a(t) = 3\mathrm{i}t^4 + t + 3\mathrm{i}t^{-2}$$

are shown in Figure 23.5.

Applications:

1. [RT94] Discretization of the one-dimensional convection-diffusion equation

$$\nu u''(x) + u'(x) = f(x), \quad u(0) = u(1) = 0$$

for $x \in [0, 1]$ with second-order centered finite differences on a uniform grid with spacing $h = 1/(n+1)$ between grid points results in an $n \times n$ Toeplitz matrix with symbol

$$a(t) = \left(\frac{\nu}{h^2} + \frac{1}{2h}\right)t - \left(\frac{2\nu}{h^2}\right) + \left(\frac{\nu}{h^2} - \frac{1}{2h}\right)t^{-1}.$$

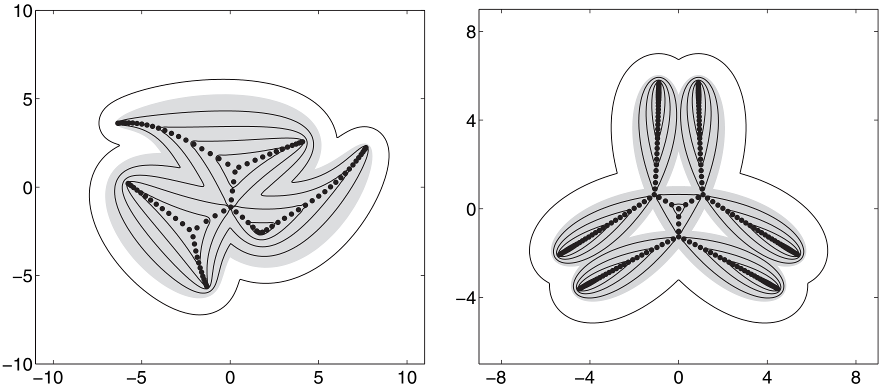

FIGURE 23.5 Spectra (solid dots) and ε-pseudospectra of Toeplitz matrices from Example 2 with the first symbol on the left ($n = 100$) and the second symbol on the right ($n = 200$), both with $\varepsilon = 10^0$, $10^{-2}, \ldots, 10^{-8}$. In each plot, the gray region is the spectrum of the underlying infinite dimensional Toeplitz operator.

On the right-most part of the spectrum, both the eigenvalues and pseudospectra of the discretization matrix converge to those of the underlying differential operator

$$\mathcal{L}u = \nu u'' + u'$$

whose domain is the space of functions that are square-integrable over $[0, 1]$ and satisfy the boundary conditions $u(0) = u(1) = 0$; see Figure 23.6. (The pseudospectra should be computed in a norm that approximates the $L^2(0, 1)$ norm on the uniform grid. In the language of Fact 23.4.7, using the trapezoid rule to approximate this norm yields a weight matrix $W = \mathrm{diag}(h, \ldots, h)$ that has no effect on the 2-norm pseudospectra.)

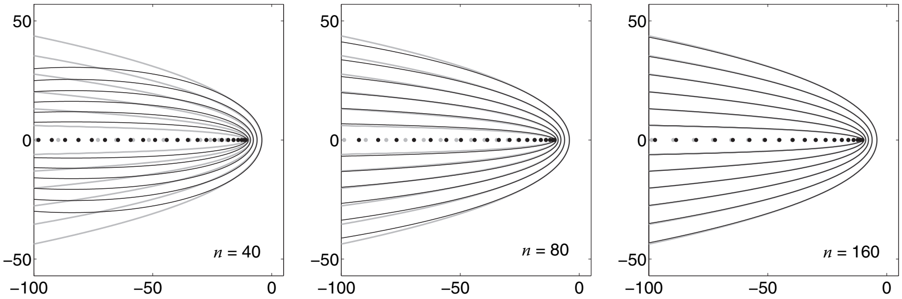

FIGURE 23.6 Spectra (solid dots) and ε-pseudospectra of Toeplitz matrices for the discretization of a convection–diffusion operator described in Application 1 with $\nu = 1/50$ and three values of n; $\varepsilon = 10^{-1}$, $10^{-2}, \ldots, 10^{-6}$. The gray dots and lines in each plot show eigenvalues and pseudospectra of the differential operator to which the matrix spectra and pseudospectra converge.

23.3 Behavior of Functions of Matrices

In practice, pseudospectra are most often used to investigate the behavior of a function of a matrix. Does the solution $\mathbf{x}(t) = e^{tA}\mathbf{x}(0)$ or $\mathbf{x}_k = A^k\mathbf{x}_0$ of the linear dynamical system $\mathbf{x}'(t) = A\mathbf{x}(t)$ or $\mathbf{x}_{k+1} = A\mathbf{x}_k$ grow or decay as $t, k \to \infty$? Eigenvalues provide an answer: If $\sigma(A)$ lies in the open unit disk or left half-plane, the solution must eventually decay.

However, the results described in this section show that if ε-pseudoeigenvalues of A extend well beyond the unit disk or left half-plane for small values of ε, then the system must exhibit transient growth for some initial states. While such growth is notable even for purely linear problems, it should spark special caution when observed for a dynamical system that arises from the linearization of a nonlinear system about a steady state based on the assumption that disturbances from that state are small in magnitude. This reasoning has been applied extensively in recent years in fluid dynamics; see, e.g., [TTR93].

Definitions:

The ***ε*-pseudospectral abscissa** of A measures the right-most extent of $\sigma_\varepsilon(A)$: $\alpha_\varepsilon(A) = \sup_{z\in\sigma_\varepsilon(A)} \operatorname{Re} z$.

The ***ε*-pseudospectral radius** of A measures the maximum magnitude in $\sigma_\varepsilon(A)$: $\rho_\varepsilon(A) = \sup_{z\in\sigma_\varepsilon(A)} |z|$.

Facts: [TE05, §§14–19]

1. For $\varepsilon > 0$, $\sup_{t\in\mathbb{R},t\geq 0} \|e^{tA}\| \geq \alpha_\varepsilon(A)/\varepsilon$.
2. For $\varepsilon > 0$, $\sup_{k\in\mathbb{N},k\geq 0} \|A^k\| \geq (\rho_\varepsilon(A)-1)/\varepsilon$.
3. For any function f that is analytic on the spectrum of A,
$$\|f(A)\| \geq \max_{\lambda\in\sigma(A)} |f(\lambda)|.$$
Equality holds when $\|\cdot\|$ is the natural norm in an inner product space in which A is normal.
4. In the special case of matrix exponentials e^{tA} and matrix powers A^k, this last fact implies that
$$\|e^{tA}\| \geq e^{t\alpha(A)}, \quad \|A^k\| \geq \rho(A)^k$$
for all $t \geq 0$ and integers $k \geq 0$, where $\alpha(A) = \max_{\lambda\in\sigma(A)} \operatorname{Re}\lambda$ is the spectral abscissa and $\rho(A) = \max_{\lambda\in\sigma(A)} |\lambda|$ is the spectral radius.
5. Let Γ_ε be a finite union of Jordan curves containing $\sigma_\varepsilon(A)$ in their collective interior for some $\varepsilon > 0$, and suppose f is a function analytic on Γ_ε and its interior. Then
$$\|f(A)\| \;\leq\; \frac{L_\varepsilon}{2\pi\varepsilon} \max_{z\in\Gamma_\varepsilon} |f(z)|,$$
where L_ε denotes the arc-length of Γ_ε.
6. In the special case of matrix exponentials e^{tA} and matrix powers A^k, this last fact implies that for all $t \geq 0$ and integers $k \geq 0$,
$$\|e^{tA}\| \;\leq\; \frac{L_\varepsilon}{2\pi\varepsilon} e^{t\alpha_\varepsilon(A)}, \quad \|A^k\| \;\leq\; \rho_\varepsilon(A)^{k+1}/\varepsilon.$$
In typical cases, larger values of ε give superior bounds for small t and k, while smaller values of ε yield more descriptive bounds for larger t and k; see Figure 23.7.
7. Suppose $z \in \mathbb{C}\setminus\sigma(A)$ with $a \equiv \operatorname{Re} z$ and $\varepsilon \equiv 1/\|(zI-A)^{-1}\|$. Provided $a > \varepsilon$, then for any fixed $\tau > 0$,
$$\sup_{0<t\leq\tau} \|e^{tA}\| \geq \frac{ae^{\tau a}}{a+\varepsilon(e^{\tau a}-1)}.$$
8. Suppose $z \in \mathbb{C}\setminus\sigma(A)$ with $a \equiv \operatorname{Re} z$ and $\varepsilon \equiv 1/\|(zI-A)^{-1}\|$, and that $\|e^{\tau A}\| \leq M$ for all $\tau > 0$ with $M \geq a/\varepsilon$. Then for any $t > 0$,
$$\|e^{tA}\| \geq e^{ta}(1-\varepsilon M/a) + \varepsilon M/a.$$

9. Suppose $z \in \mathbb{C} \setminus \sigma(A)$ with $r \equiv |z|$ and $\varepsilon \equiv 1/\|(zI - A)^{-1}\|$. Provided $r > 1 + \varepsilon$, then for any fixed integer $\kappa \geq 1$,

$$\sup_{0<k\leq\kappa} \|A^k\| \geq \frac{r^\kappa(r-1-\varepsilon) + \varepsilon r^{\kappa-1}}{(r-1-\varepsilon) + \varepsilon r^{\kappa-1}}.$$

10. Suppose $z \in \mathbb{C} \setminus \sigma(A)$ with $r \equiv |z|$ and $\varepsilon \equiv 1/\|(zI - A)^{-1}\|$, and that $\|A^\kappa\| \leq M$ for all integers $\kappa \geq 0$ with $M \geq (r-1)/\varepsilon$. Then for any integer $k \geq 0$,

$$\|A^k\| \geq r^k(r - 1 - \varepsilon M) + \varepsilon M.$$

11. For any $A \in \mathbb{C}^{n\times n}$,

$$\|A^k\| < e\,(k+1) \sup_{\varepsilon>0} \frac{\rho_\varepsilon(A) - 1}{\varepsilon}.$$

12. (Kreiss Matrix Theorem) For any $A \in \mathbb{C}^{n\times n}$,

$$\sup_{\varepsilon>0} \frac{\rho_\varepsilon(A) - 1}{\varepsilon} \;\leq\; \sup_{k\geq 0} \|A^k\| \;\leq\; e\,n \sup_{\varepsilon>0} \frac{\rho_\varepsilon(A) - 1}{\varepsilon}.$$

13. [GT93] There exist matrices A and B such that, in the induced 2-norm, $\sigma_\varepsilon(A) = \sigma_\varepsilon(B)$ for all $\varepsilon > 0$, yet $\|f(A)\|_2 \neq \|f(B)\|_2$ for some polynomial f; see Example 2. That is, even if the 2-norm of the resolvents of A and B are identical for all $z \in \mathbb{C}$, the norms of other matrix functions in A and B need not agree. (Curiously, if the *Frobenius* norm of the resolvents of A and B agree for all $z \in \mathbb{C}$, then $\|f(A)\|_F = \|f(B)\|_F$ for all polynomials f.)
14. [Ran07] Let $\alpha_2, \ldots, \alpha_m$ and $\beta_2, \ldots, \beta_m$ be any two submultiplicative sequences. (A sequence $s_2, \ldots, s_m$ is submultiplicative if $s_{j+k} \leq s_j s_k$ for all $j, k \in \{2, \ldots, m\}$ such that $j + k \leq m$.) There exist matrices A and B of dimension $n = 2m + 3$ that have identical 2-norm ε-pseudospectra for all $\varepsilon > 0$, yet $\|A^k\| = \alpha_k$ and $\|B^k\| = \beta_k$ for all $k = 2, \ldots, m$.
15. [RR11] There exist matrices with simple eigenvalues that have superidentical 2-norm pseudospectra (i.e., all singular values of the resolvents of A and B are identical for all complex $z \notin \sigma(A) = \sigma(B)$), yet $\|A^2\|_2 \neq \|B^2\|_2$; see Example 3.

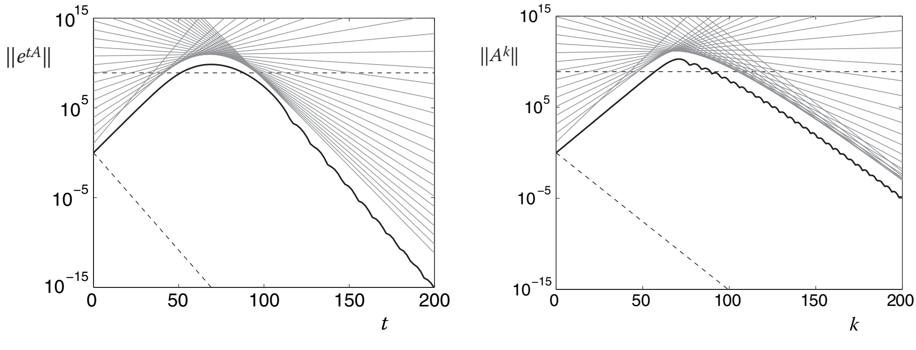

FIGURE 23.7 The functions $\|e^{tA}\|$ and $\|A^k\|$ exhibit transient growth before exponential decay for the Toeplitz matrix of dimension $n = 50$, whose pseudospectra were illustrated in Figure 23.4. The horizontal dashed lines show the lower bounds on maximal growth given in Facts 1 and 2, while the lower dashed lines show the lower bounds of Fact 4. The gray lines show the upper bounds in Fact 6 for $\varepsilon = 10^{-1}, 10^{-2}, \ldots, 10^{-28}$ (ordered by decreasing slope).

Examples:

1. Consider the tridiagonal Toeplitz matrix of dimension $n = 50$ from Example 23.2.1, whose pseudospectra were illustrated in Figure 23.4. Since all the eigenvalues of this matrix are contained in both the left half-plane and the unit disk, $e^{tA} \to 0$ as $t \to \infty$ and $A^k \to 0$ as $k \to \infty$. However, $\sigma_\varepsilon(A)$ extends far into the right half-plane and beyond the unit disk even for ε as small as 10^{-7}. Consequently, the lower bounds in Facts 1 and 2 guarantee that $\|e^{tA}\|$ and $\|A^k\|$ exhibit transient growth before their eventual decay; results such as Fact 6 limit the extent of the transient growth. These bounds are illustrated in Figure 23.7. (For a similar example involving a different matrix, see the "Transient" demonstration in [Wri02b].)
2. [GT93] The matrices

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \sqrt{2} \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \qquad B = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

   have the same 2-norm ε-pseudospectra for all $\varepsilon > 0$. However, $\|A\|_2 = \sqrt{2} > 1 = \|B\|_2$.
3. [RR11] The matrices

$$A = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 180 & -360 & 0 & 0 \\ -90 + 120\sqrt{5} & 180 + 60\sqrt{5} & 120\sqrt{5} & 0 \\ 450 & -180 & -360 & 216\sqrt{5} \end{bmatrix}$$

   and

$$B = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 120 & -360 & 0 & 0 \\ 45\sqrt{130} - 15\sqrt{26} & 45\sqrt{26} + 15\sqrt{130} & 120\sqrt{5} & 0 \\ 30\sqrt{130} & 10\sqrt{130} & 80\sqrt{5} & 216\sqrt{5} \end{bmatrix}$$

   have simple eigenvalues and superidentical 2-norm ε-pseudospectra for all $\varepsilon > 0$, yet $\|A^2\|_2 \neq \|B^2\|_2$.

Applications:

1. Fact 5 leads to a convergence result for the GMRES algorithm (Chapter 54), which constructs estimates $\mathbf{x}_k$ to the solution $\mathbf{x}$ of the linear system $A\mathbf{x} = \mathbf{b}$. The kth residual $\mathbf{r}_k = \mathbf{b} - A\mathbf{x}_k$ is bounded by

$$\frac{\|\mathbf{r}_k\|_2}{\|\mathbf{r}_0\|_2} \le \frac{L_\varepsilon}{2\pi\varepsilon} \min_{\substack{p \in \mathbb{C}[z;k] \\ p(0)=1}} \max_{z \in \Gamma_\varepsilon} |p(z)|,$$

   where $\mathbb{C}[z;k]$ denotes the set of polynomials of degree k or less, Γ_ε is a finite union of Jordan curves containing $\sigma_\varepsilon(A)$ in their collective interior for some $\varepsilon > 0$, and L_ε is the arc-length of Γ_ε.
2. For further examples of the use of pseudospectra to analyze matrix iterations and the stability of discretizations of differential equations, see [TE05, §§24–34].

23.4 Computation of Pseudospectra

This 2 describes techniques for computing and approximating pseudospectra, focusing primarily on the induced matrix 2-norm, the case most studied in the literature and for which very satisfactory algorithms exist. For further details, see [Tre99], [TE05, §§39–44], or [Wri02a].

Facts: [TE05]

1. There are two general approaches to computing pseudospectra, both based on the expression for $\sigma_\varepsilon(A)$ in Fact 23.1.1(a). The most widely used method computes the resolvent norm, $\|(zI - A)^{-1}\|_2$, on a grid of points in the complex plane and submits the results to a contour-plotting program; the second approach uses a curve-tracing algorithm to track the ε^{-1}-level curve of the resolvent norm [Brü96]. Both approaches exploit the fact that the 2-norm of the resolvent is the reciprocal of the minimum singular value of $zI - A$. A third approach, based on the characterization of $\sigma_\varepsilon(A)$ as the set of all ε-pseudoeigenvalues, *approximates* $\sigma_\varepsilon(A)$ by the union of the eigenvalues of $A + E$ for randomly generated $E \in \mathbb{C}^{n\times n}$ with $\|E\| < \varepsilon$.
2. For dense matrices A, the computation of the minimum singular value of $zI - A$ requires $\mathcal{O}(n^3)$ floating point operations for each distinct value of z. Hence, the contour-plotting approach to computing pseudospectra based on a grid of $m \times m$ points in the complex plane, implemented via the most naive method, requires $\mathcal{O}(m^2n^3)$ operations.
3. [Lui97] Improved efficiency is obtained through the use of iterative methods for computing the minimum singular value of the resolvent. The most effective methods (inverse iteration or the inverse Lanczos method) require matrix-vector products of the form $(zI - A)^{-1}\mathbf{x}$ at each iteration. For dense A, this approach requires $\mathcal{O}(n^3)$ operations per grid point. One can decrease this labor to $\mathcal{O}(n^2)$ by first reducing A to Schur form, $A = UTU^*$, and then noting that $\|(zI - A)^{-1}\|_2 = \|(zI - T)^{-1}\|_2$. Vectors of the form $(zI - T)^{-1}\mathbf{x}$ can be computed in $\mathcal{O}(n^2)$ operations since T is triangular. As the inverse iteration and inverse Lanczos methods typically converge to the minimum singular value in a small number of iterations at each grid point, the total complexity of the contour-plotting approach is $\mathcal{O}(n^3 + m^2n^2)$.
4. For large-scale problems (say, $n > 1000$), the cost of preliminary triangularization can be prohibitive. Several alternatives are available: Use sparse direct or iterative methods to compute $(zI - A)^{-1}\mathbf{x}$ at each grid point, or reduce the dimension of the problem by replacing A with a smaller matrix, such as the $(m+1)\times m$ upper Hessenberg matrix in an Arnoldi decomposition, or U^*AU, where the columns of $U \in \mathbb{C}^{n\times m}$ form an orthonormal basis for an invariant subspace corresponding to physically relevant eigenvalues, with $m \ll n$. As per results stated in Fact 23.1.9, the pseudospectra of these smaller matrices provide a lower bounds on the pseudospectra of A.
5. [Wri02b] EigTool is a freely available MATLAB package based on a highly efficient, robust implementation of the grid-based method with preliminary triangularization and inverse Lanczos iteration. For large-scale problems, EigTool uses ARPACK (Chapter 94), to compute a subspace that includes an invariant subspace associated with eigenvalues in a given region of the complex plane. The EigTool software, which was used to compute the pseudospectra shown throughout this 2, can be downloaded from `http://www.comlab.ox.ac.uk/pseudospectra/eigtool`.
6. Curve-tracing algorithms can also benefit from iterative computation of the resolvent norm, though the standard implementation requires both left and right singular vectors associated with the minimal singular value [Brü96]. Robust implementations require measures to ensure that all components of $\sigma_\varepsilon(A)$ have been located and to

handle cusps in the boundary; see, e.g., [BG01].

7. Software for computing 2-norm pseudospectra can be used to compute pseudospectra in any norm induced by an inner product. Suppose the inner product of $\mathbf{x}$ and $\mathbf{y}$ is given by $(\mathbf{x},\mathbf{y})_W = (W\mathbf{x},\mathbf{y})$, where $(\cdot,\cdot)$ denotes the Euclidean inner product and $W = LL^*$, where L^* denotes the conjugate transpose of L. Then the W-norm pseudospectra of A are equal to the 2-norm pseudospectra of L^*AL^{-*}.
8. For norms not associated with inner products, all known grid-based algorithms require $\mathcal{O}(n^3)$ operations per grid point, typically involving the explicit computation of the resolvent $(zI - A)^{-1}$. Higham and Tisseur [HT00] have proposed an efficient approach for approximating 1-norm pseudospectra using a norm estimator.
9. [BLO03],[MO05] There exist efficient algorithms, based on Fact 23.1.7, for computing the 2-norm pseudospectral radius and abscissa without first determining the entire pseudospectrum. Alternative algorithms that avoid dense matrix factorizations have been proposed to compute these quantities for large, sparse matrices [GO11].

23.5 Extensions

The previous sections address the standard formulation of the ε-pseudospectrum, the union of all eigenvalues of $A + E$ for a square matrix A and general complex perturbations E, with $\|E\| < \varepsilon$. Natural modifications restrict the structure of E or adapt the definition to more general eigenvalue problems. The former topic has attracted considerable attention in the control theory literature and is presented in detail in [HP05].

Definitions:

The **structured ε-pseudospectrum** of the matrix $A \in \mathbb{C}^{n\times n}$, for $\varepsilon > 0$, is the set

$$\sigma_\varepsilon^{\mathbb{S}}(A) = \{z \in \mathbb{C} : z \in \sigma(A+E) \text{ for some } E \in \mathbb{S},\ \|E\| < \varepsilon\},$$

where $\mathbb{S} \subseteq \mathbb{C}^{n\times n}$ comprises all matrices with some particular structure.

The **real structured ε-pseudospectrum** of $A \in \mathbb{R}^{n\times n}$ for $\varepsilon > 0$ is the set

$$\sigma_\varepsilon^{\mathbb{R}}(A) = \{z \in \sigma(A+E) : E \in \mathbb{R}^{n\times n}, \|E\| < \varepsilon\},$$

i.e., $\sigma_\varepsilon^{\mathbb{R}}(A)$ is the structured ε-pseudospectrum with $\mathbb{S} = \mathbb{R}$.

The **spectral value set** of the matrix triplet (A, B, C), $A \in \mathbb{C}^{n\times n}$, $B \in \mathbb{C}^{n\times m}$, $C \in \mathbb{C}^{p\times n}$, for $\varepsilon > 0$ is the set

$$\sigma_\varepsilon(A; B, C) = \{z \in \mathbb{C} : z \in \sigma(A + BEC) \text{ for some } E \in \mathbb{C}^{m\times p},\ \|E\| < \varepsilon\}.$$

The **ε-pseudospectrum of a rectangular matrix** $A \in \mathbb{C}^{n\times m}$ $(n \geq m)$ for $\varepsilon > 0$ is the set

$$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : (A+E)\mathbf{x} = z\widetilde{I}\mathbf{x} \text{ for some } \mathbf{x} \neq 0 \text{ and } \|E\| < \varepsilon\},$$

where $\widetilde{I}$ denotes the $n \times m$ matrix that has the $m \times m$ identity in the first m rows and is zero elsewhere.

[Ruh95] For $A \in \mathbb{C}^{n\times n}$ and invertible $B \in \mathbb{C}^{n\times n}$, the **$\varepsilon$-pseudospectrum of the matrix pencil** $A - \lambda B$ (or generalized eigenvalue problem $A\mathbf{x} = \lambda B\mathbf{x}$) for $\varepsilon > 0$ is the set

$$\sigma_\varepsilon(A, B) = \sigma_\varepsilon(B^{-1}A).$$

[TH01] The **ε-pseudospectrum of the matrix polynomial** $P(\lambda)$ (or polynomial eigenvalue problem $P(\lambda)\mathbf{x} = \mathbf{0}$), where $P(\lambda) = A_0 + A_1\lambda + \cdots + \lambda^d A_d$ and $\varepsilon > 0$, is the set

$$\begin{aligned}\sigma_\varepsilon(P) = \{z \in \mathbb{C} : z \in \sigma(P+E) &\text{ for some}\\ &E(\lambda) = E_0 + \lambda E_1 + \cdots + \lambda^d E_d,\ \|E_j\| \leq \varepsilon\alpha_j, \quad j = 0, \ldots, d\},\end{aligned}$$

for nonnegative $\alpha_0, \ldots, \alpha_d$. For most applications, one would either take $\alpha_j = 1$ for all j, or $\alpha_j = \|A_j\|$. (This definition differs considerably from the one given for the pseudospectrum of a matrix pencil. In particular, when $d = 1$ the present definition *does not* reduce to the above definition for the pencil; see Fact 6 below.)

[MGW06] The **ε-pseudospectrum of the nonlinear eigenvalue problem** $F(\lambda)\mathbf{x} = \mathbf{0}$ and $\varepsilon > 0$ is the set

$$\begin{aligned}\sigma_\varepsilon(F) = \{z \in \mathbb{C} : z \in \sigma(F + E) \text{ for some} \\ E(\lambda) = f_0(\lambda)E_0 + \cdots + f_d(\lambda)E_d,\ \|E\|_{\text{glob}} \le \varepsilon\},\end{aligned}$$

where

$$F(z) = \sum_{j=0}^{d} A_j f_j(z),$$

for matrices $A_j \in \mathbb{C}^{n\times n}$ and entire functions $f_j : \mathbb{C} \to \mathbb{C}$, $j = 0, \ldots, d$, and, e.g.,

$$\|E\|_{\text{glob}} = \left\| \begin{bmatrix} w_0\|E_0\| \\ \vdots \\ w_d\|E_d\| \end{bmatrix} \right\|_p$$

for some vector p-norm, $p \in [1, \infty]$, and weights $w_0, \ldots, w_d$. (A point $\lambda \in \mathbb{C}$ is in $\sigma(F)$ provided there exists some nonzero $\mathbf{x} \in \mathbb{C}^n$ such that $F(\lambda)\mathbf{x} = \mathbf{0}$.) Such pseudospectra have been used to analyze delay differential equations, in which case one or more of the functions f_j are exponentials. (This definition subsumes the earlier one for matrix polynomials, taking $f_j(z) = z^j$, $w_j = 1/\alpha_j$, and $p = \infty$, provided all weights $\alpha_j > 0$.)

Facts:

1. [Rum06] In the definition of the structured ε-pseudospectrum $\sigma_\varepsilon^{\mathbb{S}}(A)$, the set $\mathbb{S}$ is often taken to preserve some structure found in A itself, e.g., sparsity pattern, Toeplitz structure, nonnegativity, stochasticity, etc. Such structured pseudospectra can be difficult to compute or approximate. However, if $\mathbb{S}$ comprises one of a distinguished list of structures (complex symmetric, persymmetric, circulant, Toeplitz, symmetric Toeplitz, Hankel, or persymmetric Hankel matrices) and $A \in \mathbb{S}$, then $\sigma_\varepsilon^{\mathbb{S}}(A) = \sigma_\varepsilon(A)$ for all $\varepsilon > 0$, i.e., the structured pseudospectrum is the same as the unstructured pseudospectrum. If $\mathbb{S}$ comprises Hermitian matrices and $A \in \mathbb{S}$, then $\sigma_\varepsilon^{\mathbb{S}}(A) = \sigma_\varepsilon(A) \cap \mathbb{R}$; if $\mathbb{S}$ comprises skew-Hermitian matrices and $A \in \mathbb{S}$, then $\sigma_\varepsilon^{\mathbb{S}}(A) = \sigma_\varepsilon(A) \cap \mathrm{i}\mathbb{R}$.
2. [Kar03] Unlike the cases cited in Fact 1, the real structured pseudospectrum is generally distinct from the unstructured pseudospectrum. Indeed, the above definition of $\sigma_\varepsilon^{\mathbb{R}}(A)$ is equivalent to
$$\sigma_\varepsilon^{\mathbb{R}}(A) = \{z \in \mathbb{C} : r(A, z) < \varepsilon\},$$
where
$$r(A, z)^{-1} = \inf_{\gamma\in(0,1)} s_2\left(\begin{bmatrix} \operatorname{Re}(zI - A)^{-1} & -\gamma\operatorname{Im}(zI - A)^{-1} \\ \gamma^{-1}\operatorname{Im}(zI - A)^{-1} & \operatorname{Re}(zI - A)^{-1} \end{bmatrix}\right)$$
and $s_2(\cdot)$ denotes the second largest singular value. From this formulation, one can derive algorithms for computing $\sigma_\varepsilon^{\mathbb{R}}(A)$ akin to those used for computing $\sigma_\varepsilon(A)$.
3. [HP92, HK93] The previous definition of the spectral value set $\sigma_\varepsilon(A; B, C)$ is equivalent to
$$\sigma_\varepsilon(A; B, C) = \{z \in \mathbb{C} : \|C(zI - A)^{-1}B\| > \varepsilon^{-1}\}.$$

4. [WT02] The previous definition of the ε-pseudospectrum $\sigma_\varepsilon(A)$ of a rectangular matrix $A \in \mathbb{C}^{n\times m}$, $n \geq m$, is equivalent to

$$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : \|(z\widetilde{I} - A)^\dagger\| > \varepsilon^{-1}\},$$

where $(\cdot)^\dagger$ denotes the Moore–Penrose pseudoinverse and $\widetilde{I}$ denotes the $n \times m$ matrix that has the $m \times m$ identity in the first m rows and is zero elsewhere.

5. The following facts apply to the ε-pseudospectrum of a rectangular matrix $A \in \mathbb{C}^{m\times n}$, $m \geq n$.

   (a) [WT02] It is possible that $\sigma_\varepsilon(A) = \emptyset$.

   (b) [BLO04] For $A \in \mathbb{C}^{m\times n}$, $m \geq n$, and any $\varepsilon > 0$, the set $\sigma_\varepsilon(A)$ contains no more than $2n^2 - n + 1$ connected components.

6. [TE05] Alternative definitions have been proposed for the pseudospectrum of the matrix pencil $A - \lambda B$. The definition presented previously has the advantage that the pseudospectrum is invariant to premultiplication of the pencil by a nonsingular matrix, which is consistent with the fact that premultiplication of the differential equation $B\mathbf{x}' = A\mathbf{x}$ by a nonsingular matrix does not affect the solution $\mathbf{x}$. Here are two alternative definitions, *neither of which are equivalent to the previous definition.*

   (a) [Rie94] If B is Hermitian positive definite with Cholesky factorization $B = LL^*$, then the pseudospectrum of the pencil can be defined in terms of the standard pseudospectrum of a transformed problem:

$$\sigma_\varepsilon(A, B) = \sigma_\varepsilon(L^{-1}AL^{-*}).$$

   (b) [FGN96, TH01] The following definition is more appropriate for the study of eigenvalue perturbations:

$$\begin{aligned}\sigma_\varepsilon(A, B) = \{z \in \mathbb{C} : (A + E_0)\mathbf{x} = z(B + E_1)\mathbf{x} \text{ for some}\\ \mathbf{x} \neq \mathbf{0} \text{ and } E_0,\ E_1 \text{ with } \|E_0\| < \varepsilon\alpha_0,\ \|E_1\| < \varepsilon\alpha_1\},\end{aligned}$$

   where generally either $\alpha_j = 1$ for $j = 0, 1$, or $\alpha_0 = \|A\|$ and $\alpha_1 = \|B\|$. This is a special case of the definition given above for the pseudospectrum of a matrix polynomial.

7. [TH01] The previous definition of the ε-pseudospectrum of a matrix polynomial, $\sigma_\varepsilon(P)$, is equivalent to

$$\sigma_\varepsilon(P) = \{z \in \mathbb{C} : \|P(z)^{-1}\| > 1/(\varepsilon\phi(|z|))\},$$

where $\phi(z) = \sum_{j=0}^{d} \alpha_k z^k$ for the same values of $\alpha_0, \ldots, \alpha_d$ used in the earlier definition.

8. [MGW06] The ε-pseudospectrum of a nonlinear eigenvalue problem has an equivalent form similar to the one given in the previous fact for matrix polynomials; this expression varies with the norm used to measure the size of the perturbations.

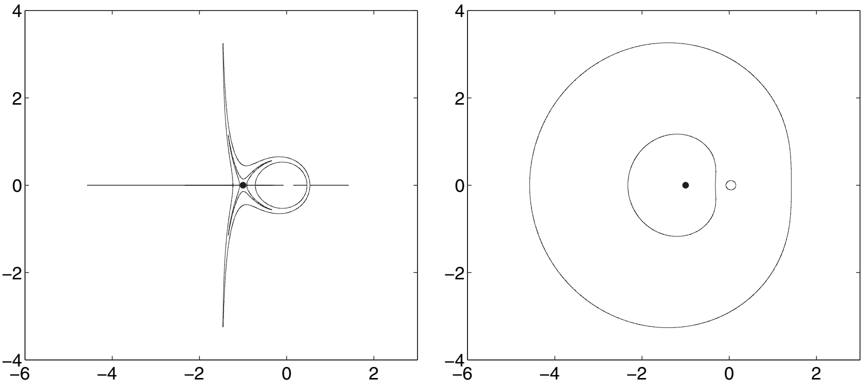

FIGURE 23.8 Spectrum (solid dot) and real structured ε-pseudospectra $\sigma_\varepsilon^{\mathbb{R}}(A)$ (left) and unstructured ε-pseudospectra $\sigma_\varepsilon(A)$ of the second matrix of Example 23.1.3 for $\varepsilon = 10^{-3}$, 10^{-4}.

Examples:

1. Figure 23.8 compares real structured ε-pseudospectra $\sigma_\varepsilon^{\mathbb{R}}(A)$ to the (unstructured) pseudospectra $\sigma_\varepsilon(A)$ for the second matrix in Example 23.1.3; cf. [TE05, Fig. 50.3].
2. Figure 23.9 shows pseudospectra of the rectangular matrix

$$A = \begin{bmatrix} 2 & -5 & 10 \\ 1 & -2 & 5\mathrm{i} \\ 0 & 0 & 1 \\ \delta & \delta & \delta \end{bmatrix},$$

which is the third matrix in Example 23.1.1, but with an extra row appended.

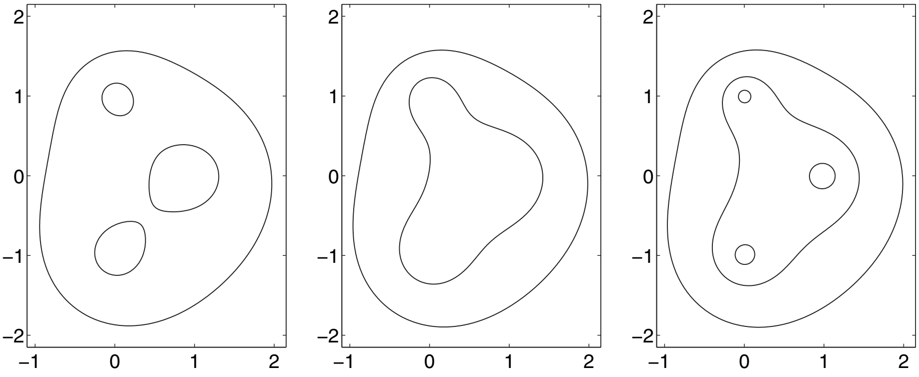

FIGURE 23.9 ε-pseudospectra of the rectangular matrix in Example 2 with $\delta = 0.02$ (left), $\delta = 0.01$ (middle), $\delta = 0.005$ (right), and $\varepsilon = 10^{-1}$, $10^{-1.5}$, and 10^{-2}. Note that in the first two plots, $\sigma_\varepsilon(A) = \emptyset$ for $\varepsilon = 10^{-2}$.

24.1 Definitions and Characterizations

Singular values and the singular value decomposition are defined in Section 5.6. Additional information on computation of the singular value decomposition can be found in Chapter 58. A brief history of the singular value decomposition and early references can be found in [HJ91, Chap. 3].

Throughout this chapter, $q = \min\{m, n\}$, and if $A \in \mathbb{C}^{n\times n}$ has real eigenvalues, then they are ordered $\lambda_1(A) \geq \cdots \geq \lambda_n(A)$.

Definitions:

For $A \in \mathbb{C}^{m\times n}$, define the **singular value vector** $\mathrm{sv}(A) = (\sigma_1(A), \ldots, \sigma_q(A))$.

For $A \in \mathbb{C}^{m\times n}$, define $r_1(A) \geq \cdots \geq r_m(A)$ and $c_1(A) \geq \cdots \geq c_n(A)$ to be the ordered Euclidean row and column lengths of A; that is, the square roots of the ordered diagonal entries of AA^* and A^*A.

For $A \in \mathbb{C}^{m\times n}$ define $|A|_{pd} = (A^*A)^{1/2}$. This is called the **spectral absolute value** of A. (This is also called the **absolute value**, but the latter term will not be used in this chapter due to potential confusion with the entry-wise absolute value of A, denoted $|A|$.)

A **polar decomposition** or **polar form** of the matrix $A \in \mathbb{C}^{m\times n}$ with $m \geq n$ is a factorization $A = UP$, where $P \in \mathbb{C}^{n\times n}$ is positive semidefinite and $U \in \mathbb{C}^{m\times n}$ satisfies $U^*U = I_n$.

Facts:

The following facts can be found in most books on matrix theory, for example [HJ91, Chap. 3] or [Bha97].

1. Take $A \in \mathbb{C}^{m\times n}$, and set
$$B = \begin{bmatrix} A & 0 \\ 0 & 0 \end{bmatrix}.$$
Then $\sigma_i(A) = \sigma_i(B)$ for $i = 1, \ldots, q$ and $\sigma_i(B) = 0$ for $i > q$. We may choose the zero blocks in B to ensure that B is square. In this way we can often generalize results on the singular values of square matrices to rectangular matrices. For simplicity of exposition, in this chapter we will sometimes state a result for square matrices rather than the more general result for rectangular matrices.
2. (Unitary invariance) Take $A \in \mathbb{C}^{m\times n}$. Then for any unitary $U \in \mathbb{C}^{m\times m}$ and $V \in \mathbb{C}^{n\times n}$,
$$\sigma_i(A) = \sigma_i(UAV), \quad i = 1, 2, \ldots, q.$$
3. Take $A, B \in \mathbb{C}^{m\times n}$. There are unitary matrices $U \in \mathbb{C}^{m\times m}$ and $V \in \mathbb{C}^{n\times n}$ such that $A = UBV$ if and only if $\sigma_i(A) = \sigma_i(B)$, $i = 1, 2, \ldots, q$.
4. Let $A \in \mathbb{C}^{m\times n}$. Then $\sigma_i^2(A) = \lambda_i(AA^*) = \lambda_i(A^*A)$ for $i = 1, 2, \ldots, q$.
5. Let $A \in \mathbb{C}^{m\times n}$. Let $\mathcal{S}_i$ denote the set of subspaces of $\mathbb{C}^n$ of dimension i. Then for $i = 1, 2, \ldots, q$,
$$\sigma_i(A) = \min_{\mathcal{X}\in\mathcal{S}_{n-i+1}} \max_{\mathbf{x}\in\mathcal{X}, \|\mathbf{x}\|_2=1} \|A\mathbf{x}\|_2 = \min_{\mathcal{Y}\in\mathcal{S}_{i-1}} \max_{\mathbf{x}\perp\mathcal{Y}, \|\mathbf{x}\|_2=1} \|A\mathbf{x}\|_2,$$
$$\sigma_i(A) = \max_{\mathcal{X}\in\mathcal{S}_{i}} \min_{\mathbf{x}\in\mathcal{X}, \|\mathbf{x}\|_2=1} \|A\mathbf{x}\|_2 = \max_{\mathcal{Y}\in\mathcal{S}_{n-i}} \min_{\mathbf{x}\perp\mathcal{Y}, \|\mathbf{x}\|_2=1} \|A\mathbf{x}\|_2.$$
6. Let $A \in \mathbb{C}^{m\times n}$and define the Hermitian matrix
$$J = \begin{bmatrix} 0 & A \\ A^* & 0 \end{bmatrix} \in \mathbb{C}^{m+n,m+n}.$$
The eigenvalues of J are $\pm\sigma_1(A), \ldots, \pm\sigma_q(A)$ together with $|m-n|$ zeros. The matrix J is called the Jordan–Wielandt matrix. Its use allows one to deduce singular value results from results for eigenvalues of Hermitian matrices.
7. Take $m \geq n$ and $A \in \mathbb{C}^{m\times n}$. Let $A = UP$ be a polar decomposition of A. Then $\sigma_i(A) = \lambda_i(P)$, $i = 1, 2, \ldots, q$.
8. Let $A \in \mathbb{C}^{m\times n}$ and $1 \leq k \leq q$. Then
$$\sum_{i=1}^{k} \sigma_i(A) = \max\{\text{Re tr } U^*AV : U \in \mathbb{C}^{m\times k}, V \in \mathbb{C}^{n\times k,}\ U^*U = V^*V = I_k\},$$
$$\prod_{i=1}^{k} \sigma_i(A) = \max\{|\text{det}U^*AV| : U \in \mathbb{C}^{m\times k}, V \in \mathbb{C}^{n\times k},\ U^*U = V^*V = I_k\}.$$
If $m = n$, then
$$\sum_{i=1}^{n} \sigma_i(A) = \max\left\{\sum_{i=1}^{n} |(U^*AU)_{ii}| : U \in \mathbb{C}^{n\times n},\ U^*U = I_n\right\}.$$
We cannot replace the n by a general $k \in \{1, \ldots, n\}$.

9. Let $A \in \mathbb{C}^{m\times n}$.
   (a) $\sigma_i(A^T) = \sigma_i(A^*) = \sigma_i(\bar{A}) = \sigma_i(A)$, for $i = 1, 2, \dots, q$.
   (b) Let $k = \operatorname{rank}(A)$. Then $\sigma_i(A^\dagger) = \sigma_{k-i+1}^{-1}(A)$ for $i = 1, \dots, k$, and $\sigma_i(A^\dagger) = 0$ for $i = k+1, \dots, q$. In particular, if $m = n$ and A is invertible, then
   $$\sigma_i(A^{-1}) = \sigma_{n-i+1}^{-1}(A), \quad i = 1, \dots, n.$$
   (c) For any $j \in \mathbb{N}$
   $$\sigma_i((A^*A)^j) = \sigma_i^{2j}(A), \quad i = 1, \dots, q;$$
   $$\sigma_i((A^*A)^j A^*) = \sigma_i(A(A^*A)^j) = \sigma_i^{2j+1}(A) \quad i = 1, \dots, q.$$
10. Let UP be a polar decomposition of $A \in \mathbb{C}^{m\times n}$ $(m \geq n)$. The positive semidefinite factor P is uniquely determined and is equal to $|A|_{pd}$. The factor U is uniquely determined if A has rank n. If A has singular value decomposition $A = U_1 \Sigma U_2^*$ $(U_1 \in \mathbb{C}^{m\times n}$, $U_2 \in \mathbb{C}^{n\times n})$, then $P = U_2 \Sigma U_2^*$, and U may be taken to be $U_1 U_2^*$.
11. Take $A, U \in \mathbb{C}^{n\times n}$ with U unitary. Then $A = U|A|_{pd}$ if and only if $A = |A^*|_{pd} U$.

Examples:

1. Take
   $$A = \begin{bmatrix} 11 & -3 & -5 & 1 \\ 1 & -5 & -3 & 11 \\ -5 & 1 & 11 & -3 \\ -3 & 11 & 1 & -5 \end{bmatrix}.$$
   The singular value decomposition of A is $A = U\Sigma V^*$, where $\Sigma = \operatorname{diag}(20, 12, 8, 4)$, and
   $$U = \frac{1}{2}\begin{bmatrix} -1 & 1 & -1 & 1 \\ -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix} \quad \text{and} \quad V = \frac{1}{2}\begin{bmatrix} -1 & 1 & -1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & -1 & -1 & 1 \\ -1 & -1 & 1 & 1 \end{bmatrix}.$$
   The singular values of A are $20, 12, 8, 4$. Let Q denote the permutation matrix that takes (x_1, x_2, x_3, x_4) to (x_1, x_4, x_3, x_2). Let $P = |A|_{pd} = QA$. The polar decomposition of A is $A = QP$. (To see this, note that a permutation matrix is unitary and that P is positive definite by Geršchgorin's theorem.) Note also that $|A|_{pd} \neq |A^*|_{pd} = AQ$.

24.2 Singular Values of Special Matrices

In this section, we present some matrices where the singular values (or some of the singular values) are known, and facts about the singular values of certain structured matrices.

Facts:

The following results can be obtained by straightforward computations if no specific reference is given.

1. Let $D = \operatorname{diag}(\alpha_1, \dots, \alpha_n)$, where the α_i are integers, and let H_1 and H_2 be Hadamard matrices. (See Section 44.2.) Then the matrix $H_1 D H_2$ has integer entries and has integer singular values $n|\alpha_1|, \dots, n|\alpha_n|$.

2. (2×2 *matrix*) Take $A \in \mathbb{C}^{2\times 2}$. Set $D = |\det(A)|^2$, $N = \|A\|_F^2$. The singular values of A are
$$\sqrt{\frac{N \pm \sqrt{N^2 - 4D}}{2}}.$$
3. Let $X \in \mathbb{C}^{m\times n}$ have singular values $\sigma_1 \geq \cdots \geq \sigma_q$ ($q = \min\{m, n\}$). Set
$$A = \begin{bmatrix} I & 2X \\ 0 & I \end{bmatrix} \in \mathbb{C}^{m+n,m+n}.$$
The $m + n$ singular values of A are
$$\sigma_1 + \sqrt{\sigma_1^2 + 1}, \ldots, \sigma_q + \sqrt{\sigma_q^2 + 1}, 1, \ldots, 1, \sqrt{\sigma_q^2 + 1} - \sigma_q, \ldots, \sqrt{\sigma_1^2 + 1} - \sigma_1.$$
4. [HJ91, Theorem 4.2.15] Let $A \in \mathbb{C}^{m_1\times n_1}$ and $B \in \mathbb{C}^{m_2\times n_2}$ have rank m and n. The nonzero singular values of $A \otimes B$ are $\sigma_i(A)\sigma_j(B)$, $i = 1, \ldots, m$, $j = 1, \ldots, n$.
5. Let $A \in \mathbb{C}^{n\times n}$ be normal with eigenvalues $\lambda_1, \ldots, \lambda_n$, and let p be a polynomial. Then the singular values of $p(A)$ are $|p(\lambda_k)|$, $k = 1, \ldots, n$. In particular, if A is a circulant with first row $a_0, \ldots, a_{n-1}$, then A has singular values
$$\left|\sum_{j=0}^{n-1} a_i e^{-2\pi ijk/n}\right|, \quad k = 1, \ldots, n.$$
6. Take $A \in \mathbb{C}^{n\times n}$ and nonzero $\mathbf{x} \in \mathbb{C}^n$. If $A\mathbf{x} = \lambda\mathbf{x}$ and $\mathbf{x}^*A = \lambda\mathbf{x}^*$, then $|\lambda|$ is a singular value of A. In particular, if A is doubly stochastic, then $\sigma_1(A) = 1$.
7. [Kit95] Let A be the companion matrix corresponding to the monic polynomial $p(t) = t^n + a_{n-1}t^{n-1} + \cdots + a_1 t + a_0$. Set $N = 1 + \sum_{i=0}^{n-1} |a_i|^2$. The n singular values of A are
$$\sqrt{\frac{N + \sqrt{N^2 - 4|a_0|^2}}{2}}, 1, \ldots, 1, \sqrt{\frac{N - \sqrt{N^2 - 4|a_0|^2}}{2}}.$$
8. [Hig96, p. 167] Take $s, c \in \mathbb{R}$ such that $s^2 + c^2 = 1$. The matrix
$$A = \operatorname{diag}(1, s, \ldots, s^{n-1}) \begin{bmatrix} 1 & -c & -c & \cdots & -c \\ & 1 & -c & \cdots & -c \\ & & \ddots & \ddots & \vdots \\ & & & \ddots & -c \\ & & & & 1 \end{bmatrix}$$
is called a Kahan matrix. If c and s are positive, then $\sigma_{n-1}(A) = s^{n-2}\sqrt{1 + c}$.
9. [GE95, Lemma 3.1] Take $0 = d_1 < d_2 < \cdots < d_n$ and $0 \neq z_i \in \mathbb{C}$. Let
$$A = \begin{bmatrix} z_1 & & & \\ z_2 & d_2 & & \\ \vdots & & \ddots & \\ z_n & & & d_n \end{bmatrix}.$$
The singular values of A satisfy the equation
$$f(t) = 1 + \sum_{i=1}^{n} \frac{|z_i|^2}{d_i^2 - t^2} = 0$$

and exactly one lies in each of the intervals $(d_1, d_2), \ldots, (d_{n-1}, d_n), (d_n, d_n + \|z\|_2)$. Let $\sigma_i = \sigma_i(A)$. The left and right ith singular vectors of A are $\mathbf{u}/\|\mathbf{u}\|_2$ and $\mathbf{v}/\|\mathbf{v}\|_2$ respectively, where

$$\mathbf{u} = \left[\frac{z_1}{d_1^2 - \sigma_i^2}, \cdots, \frac{z_n}{d_n^2 - \sigma_i^2}\right]^T \quad \text{and} \quad \mathbf{v} = \left[-1, \frac{d_2 z_2}{d_2^2 - \sigma_i^2}, \cdots, \frac{d_n z_n}{d_n^2 - \sigma_i^2}\right]^T.$$

10. (*Bidiagonal*) Take

$$B = \begin{bmatrix} \alpha_1 & \beta_1 & & \\ & \alpha_2 & \ddots & \\ & & \ddots & \beta_{n-1} \\ & & & \alpha_n \end{bmatrix} \in \mathbb{C}^{n \times n}.$$

If all the α_i and β_i are nonzero, then B is called an *unreduced bidiagonal matrix* and

(a) The singular values of B are distinct.

(b) The singular values of B depend only on the moduli of $\alpha_1, \ldots, \alpha_n, \beta_1, \ldots, \beta_{n-1}$.

(c) The largest singular value of B is a strictly increasing function of the modulus of each of the α_i and β_i.

(d) The smallest singular value of B is a strictly increasing function of the modulus of each of the α_i and a strictly decreasing function of the modulus of each of the β_i.

(e) (High relative accuracy) Take $\tau > 1$ and multiply one of the entries of B by τ to give $\hat{B}$. Then $\tau^{-1}\sigma_i(B) \le \sigma_i(\hat{B}) \le \tau\sigma_i(B)$.

11. [HJ85, Sec. 4.4, prob. 26] Let $A \in \mathbb{C}^{n \times n}$ be skew-symmetric (and possibly complex). The nonzero singular values of A occur in pairs.

24.3 Unitarily Invariant Norms

Throughout this section, $q = \min\{m, n\}$.

Definitions:

A vector norm $\|\cdot\|$ on $\mathbb{C}^{m \times n}$ is **unitarily invariant** (*u.i.*) if $\|A\| = \|UAV\|$ for any unitary $U \in \mathbb{C}^{m \times m}$ and $V \in \mathbb{C}^{n \times n}$ and any $A \in \mathbb{C}^{m \times n}$.

$\|\cdot\|_{UI}$ is used to denote a **general unitarily invariant norm**.

The **absolute value** of $\mathbf{x} = [x_i] \in \mathbb{R}^n$ is the vector $|\mathbf{x}| = [\,|x_i|\,]$.

A norm $\|\cdot\|$ on $\mathbb{R}^n$ is a **permutation invariant absolute norm** if $\|\mathbf{x}\| = \||\mathbf{x}|\|$ and $\|\mathbf{x}\| = \|P\mathbf{x}\|$ for all $\mathbf{x} \in \mathbb{R}^n$ and all permutation matrices $P \in \mathbb{R}^{n \times n}$. (Many authors call a permutation invariant absolute norm a symmetric gauge function.)

The **Ky Fan k norms** of $A \in \mathbb{C}^{m \times n}$ are

$$\|A\|_{K,k} = \sum_{i=1}^{k} \sigma_i(A), \quad k = 1, 2, \ldots, q.$$

The **Schatten-p norms** of $A \in \mathbb{C}^{m \times n}$ are

$$\|A\|_{S,p} = \left(\sum_{i=1}^{q} \sigma_i^p(A)\right)^{1/p} = \left(\text{tr } |A|_{pd}^p\right)^{1/p} \quad 0 \le p < \infty$$
$$\|A\|_{S,\infty} = \sigma_1(A)$$

(the Schatten-1 norm is often called the **nuclear norm**).

The **trace norm** (also called the **nuclear norm**) of $A \in \mathbb{C}^{m\times n}$ is

$$\|A\|_{\mathrm{tr}} = \sum_{i=1}^{q} \sigma_i(A) = \|A\|_{K,q} = \|A\|_{S,1} = \mathrm{tr}\ |A|_{pd}.$$

The **spectral norm** $\|\cdot\|_2$ is $\|A\|_2 = \sigma_1(A) = \max_{\mathbf{x}\neq 0} \frac{\|A\mathbf{x}\|_2}{\|\mathbf{x}\|_2}$, and the **Frobenius norm** $\|\cdot\|_F$ is $\|A\|_F = (\sum_{i=1}^{q} \sigma_i^2(A))^{1/2} = (\sum_{i=1}^{m}\sum_{j=1}^{n} |a_{ij}|^2)^{1/2}$; these and other norms discussed in this section are defined in Section 8.1. and discussed extensively in Chapter 50.

Warning: There is potential for considerable confusion. For example, $\|A\|_2 = \|A\|_{K,1} = \|A\|_{S,\infty}$, while $\|\cdot\|_\infty \neq \|\cdot\|_{S,\infty}$ (unless $m = 1$), and generally $\|A\|_2$, $\|A\|_{S,2}$ and $\|A\|_{K,2}$ are all different, as are $\|A\|_1$, $\|A\|_{S,1}$ and $\|A\|_{K,1}$. Nevertheless, many authors use $\|\cdot\|_k$ for $\|\cdot\|_{K,k}$ and $\|\cdot\|_p$ for $\|\cdot\|_{S,p}$.

Facts:

The following standard facts can be found in many texts, e.g., [HJ91, §3.5] and [Bha97, Chap. IV].

1. Let $\|\cdot\|$ be a norm on $\mathbb{C}^{m\times n}$. It is unitarily invariant if and only if there is a permutation invariant absolute norm g on $\mathbb{R}^q$ such that $\|A\| = g(\sigma_1(A), \ldots, \sigma_q(A))$ for all $A \in \mathbb{C}^{m\times n}$.
2. Let $\|\cdot\|$ be a unitarily invariant norm on $\mathbb{C}^{m\times n}$, and let g be the corresponding permutation invariant absolute norm g. Then the dual norms (see Chapter 50) satisfy $\|A\|^D = g^D(\sigma_1(A), \ldots, \sigma_q(A))$.
3. [HJ91, Prob. 3.5.18] The spectral norm and trace norm are duals, while the Frobenius norm is self dual. The dual of $\|\cdot\|_{S,p}$ is $\|\cdot\|_{S,\tilde{p}}$, where $1/p + 1/\tilde{p} = 1$ and

$$\|A\|_{K,k}^D = \max\left\{\|A\|_2, \frac{\|A\|_{tr}}{k}\right\}, \quad k = 1, \ldots, q.$$

4. For any $A \in \mathbb{C}^{m\times n}$, $q^{-1/2}\|A\|_F \leq \|A\|_2 \leq \|A\|_F$.
5. If $\|\cdot\|$ is a u.i. norm on $\mathbb{C}^{m\times n}$, then $N(A) = \|A^*A\|^{1/2}$ is a u.i. norm on $\mathbb{C}^{n\times n}$. A norm that arises in this way is called a *Q-norm.*
6. Let $A, B \in \mathbb{C}^{m\times n}$ be given. The following are equivalent
   (a) $\|A\|_{UI} \leq \|B\|_{UI}$ for all unitarily invariant norms $\|\cdot\|_{UI}$.
   (b) $\|A\|_{K,k} \leq \|B\|_{K,k}$ for $k = 1, 2, \ldots, q$.
   (c) $(\sigma_1(A), \ldots, \sigma_q(A)) \preceq_w (\sigma_1(B), \ldots, \sigma_q(B))$. ($\preceq_w$ is defined in Preliminaries)

   The equivalence of the first two conditions is Fan's Dominance Theorem.
7. The Ky–Fan-k norms can be represented in terms of an extremal problem involving the spectral norm and the trace norm. Take $A \in \mathbb{C}^{m\times n}$. Then

$$\|A\|_{K,k} = \min\{\|X\|_{\mathrm{tr}} + k\|Y\|_2 : X + Y = A\} \quad k = 1, \ldots, q.$$

8. [HJ91, Theorem 3.3.14] Take $A, B \in \mathbb{C}^{m\times n}$. Then

$$|\mathrm{tr} AB^*| \leq \sum_{i=1}^{q} \sigma_i(A)\sigma_i(B).$$

   This is an important result in developing the theory of unitarily invariant norms.

Examples:

1. The matrix A in Example 24.1.1 has singular values $20, 12, 8$, and 4. So

$$\|A\|_2 = 20, \quad \|A\|_F = \sqrt{624}, \quad \|A\|_{tr} = 44;$$

$$\|A\|_{K,1} = 20, \quad \|A\|_{K,2} = 32, \quad \|A\|_{K,3} = 40, \quad \|A\|_{K,4} = 44;$$

$$\|A\|_{S,1} = 44, \quad \|A\|_{S,2} = \sqrt{624}, \quad \|A\|_{S,3} = \sqrt[3]{10304} = 21.7605, \quad \|A\|_{S,\infty} = 20.$$

24.4 Inequalities

Throughout this section, $q = \min\{m, n\}$ and if $A \in \mathbb{C}^{m\times n}$ has real eigenvalues, then they are ordered $\lambda_1(A) \geq \cdots \geq \lambda_n(A)$.

Definitions:

Pinching is defined recursively. If

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \in \mathbb{C}^{m\times n}, \quad B = \begin{bmatrix} A_{11} & 0 \\ 0 & A_{22} \end{bmatrix} \in \mathbb{C}^{m\times n},$$

then B is a pinching of A. (Note that we do not require the A_{ii} to be square.) Furthermore, any pinching of B is a pinching of A.

For positive α, β, define the **measure of relative separation** $\chi(\alpha, \beta) = |\sqrt{\alpha/\beta} - \sqrt{\beta/\alpha}|$.

Facts:

The following facts can be found in standard references, for example [HJ91, Chap. 3], unless another reference is given.

1. (*Submatrices*) Take $A \in \mathbb{C}^{m\times n}$ and let B denote A with one of its rows or columns deleted. Then $\sigma_{i+1}(A) \leq \sigma_i(B) \leq \sigma_i(A), \quad i = 1, \ldots, q-1$.
2. Take $A \in \mathbb{C}^{m\times n}$ and let B be A with a row *and* a column deleted. Then

$$\sigma_{i+2}(A) \leq \sigma_i(B) \leq \sigma_i(A), \quad i = 1, \ldots, q-2.$$

   The $i+2$ cannot be replaced by $i+1$. (Example 2)
3. Take $A \in \mathbb{C}^{m\times n}$ and let B be an $(m-k) \times (n-l)$ submatrix of A. Then

$$\sigma_{i+k+l}(A) \leq \sigma_i(B) \leq \sigma_i(A), \quad i = 1, \ldots, q-(k+l).$$

4. Take $A \in \mathbb{C}^{m\times n}$ and let B be A with some of its rows or columns (or both) set to zero. Then $\sigma_i(B) \leq \sigma_i(A), \quad i = 1, \ldots, q$.
5. Let B be a pinching of A. Then $\text{sv}(B) \preceq_w \text{sv}(A)$. The inequalities $\prod_{i=1}^k \sigma_i(B) \leq \prod_{i=1}^k \sigma_i(A)$ and $\sigma_k(B) \leq \sigma_k(A)$ are not necessarily true for $k > 1$. (Example 1)
6. (*Singular values of* $A + B$) Let $A, B \in \mathbb{C}^{m\times n}$.

   (a) $\text{sv}(A+B) \preceq_w \text{sv}(A) + \text{sv}(B)$, or equivalently

$$\sum_{i=1}^k \sigma_i(A+B) \leq \sum_{i=1}^k \sigma_i(A) + \sum_{i=1}^k \sigma_i(B), \quad i = 1, \ldots, q.$$

   (b) If $i + j - 1 \leq q$ and $i, j \in \mathbb{N}$, then $\sigma_{i+j-1}(A+B) \leq \sigma_i(A) + \sigma_j(B)$.

(c) We have the weak majorization $|\mathrm{sv}(A+B)-\mathrm{sv}(A)| \preceq_w \mathrm{sv}(B)$ or, equivalently, if $1 \leq i_1 < \cdots < i_k \leq q$, then

$$\sum_{j=1}^{k} |\sigma_{i_j}(A+B) - \sigma_{i_j}(A)| \leq \sum_{j=1}^{k} \sigma_j(B),$$

$$\sum_{i=1}^{k} \sigma_{i_j}(A) - \sum_{j=1}^{k} \sigma_j(B) \leq \sum_{j=1}^{k} \sigma_{i_j}(A+B) \leq \sum_{i=1}^{k} \sigma_{i_j}(A) + \sum_{j=1}^{k} \sigma_j(B).$$

(d) [Tho75] (Thompson's Standard Additive Inequalities) If $1 \leq i_1 < \cdots < i_k \leq q$, $1 \leq i_1 < \cdots < i_k \leq q$ and $i_k + j_k \leq q + k$, then

$$\sum_{s=1}^{k} \sigma_{i_s+j_s-s}(A+B) \leq \sum_{s=1}^{k} \sigma_{i_s}(A) + \sum_{s=1}^{k} \sigma_{j_s}(B).$$

7. (*Singular values of* AB) Take $A, B \in \mathbb{C}^{n\times n}$.

(a) For all $k = 1, 2, \ldots, n$ and all $p > 0$, we have

$$\prod_{i=n}^{i=n-k+1} \sigma_i(A)\sigma_i(B) \leq \prod_{i=n}^{i=n-k+1} \sigma_i(AB),$$

$$\prod_{i=1}^{k} \sigma_i(AB) \leq \prod_{i=1}^{k} \sigma_i(A)\sigma_i(B),$$

$$\sum_{i=1}^{k} \sigma_i^p(AB) \leq \sum_{i=1}^{k} \sigma_i^p(A)\sigma_i^p(B).$$

(b) If $i, j \in \mathbb{N}$ and $i + j - 1 \leq n$, then $\sigma_{i+j-1}(AB) \leq \sigma_i(A)\sigma_j(B)$.

(c) $\sigma_n(A)\sigma_i(B) \leq \sigma_i(AB) \leq \sigma_1(A)\sigma_i(B)$, $i = 1, 2, \ldots, n$.

(d) [LM99] Take $1 \leq j_1 < \cdots < j_k \leq n$. If A is invertible and $\sigma_{j_i}(B) > 0$, then $\sigma_{j_i}(AB) > 0$ and

$$\prod_{i=n-k+1}^{n} \sigma_i(A) \leq \prod_{i=1}^{k} \max\left\{\frac{\sigma_{j_i}(AB)}{\sigma_{j_i}(B)}, \frac{\sigma_{j_i}(B)}{\sigma_{j_i}(AB)}\right\} \leq \prod_{i=1}^{k} \sigma_i(A).$$

(e) [LM99] Take invertible $S, T \in \mathbb{C}^{n\times n}$. Set $\tilde{A} = SAT$. Let the singular values of A and $\tilde{A}$ be $\sigma_1 \geq \cdots \geq \sigma_n$ and $\tilde{\sigma}_1 \geq \cdots \geq \tilde{\sigma}_n$. Then

$$\|\mathrm{diag}(\chi(\sigma_1, \tilde{\sigma}_1), , \ldots, \chi(\sigma_n, \tilde{\sigma}_n))\|_{UI} \leq \frac{1}{2}\left(\|S^* - S^{-1}\|_{UI} + \|T^* - T^{-1}\|_{UI}\right).$$

(f) [TT73] (Thompson's Standard Multiplicative Inequalities) Take $1 \leq i_1 < \cdots < i_m \leq n$ and $1 \leq j_1 < \cdots < j_m \leq n$. If $i_m + j_m \leq m + n$, then

$$\prod_{s=1}^{m} \sigma_{i_s+j_s-s}(AB) \leq \prod_{s=1}^{m} \sigma_{i_s}(A) \prod_{s=1}^{m} \sigma_{j_s}(B).$$

8. [Bha97, §IX.1] Take $A, B \in \mathbb{C}^{n\times n}$.

(a) If AB is normal, then

$$\prod_{i=1}^{k} \sigma_i(AB) \leq \prod_{i=1}^{k} \sigma_i(BA), \quad k = 1, \ldots, q,$$

and, consequently, $\mathrm{sv}(AB) \preceq_w \mathrm{sv}(BA)$, and $\|AB\|_{UI} \leq \|BA\|_{UI}$.

(b) If AB is Hermitian, then $\mathrm{sv}(AB) \preceq_w \mathrm{sv}(H(BA))$ and $\|AB\|_{UI} \leq \|H(BA)\|_{UI}$, where $H(X) = (X + X^*)/2$.

9. (*Term-wise singular value inequalities*) [Zha02, p. 28] Take $A, B \in \mathbb{C}^{m\times n}$. Then

$$2\sigma_i(AB^*) \leq \sigma_i(A^*A + B^*B), \quad i = 1, \ldots, q$$

and, more generally, if $p, \tilde{p} > 0$ and $1/p + 1/\tilde{p} = 1$, then

$$\sigma_i(AB^*) \leq \sigma_i\left(\frac{(A^*A)^{p/2}}{p} + \frac{(B^*B)^{\tilde{p}/2}}{\tilde{p}}\right) = \sigma_i\left(\frac{|A|_{pd}^{p}}{p} + \frac{|B|_{pd}^{\tilde{p}}}{\tilde{p}}\right).$$

The inequalities $2\sigma_1(A^*B) \leq \sigma_1(A^*A + B^*B)$ and $\sigma_1(A+B) \leq \sigma_1(|A|_{pd} + |B|_{pd})$ are not true in general (Example 3), but we do have

$$\|A^*B\|_{UI}^2 \leq \|A^*A\|_{UI}\|B^*B\|_{UI}.$$

10. [Bha97, Prop. III.5.1] Take $A \in \mathbb{C}^{n\times n}$. Then $\lambda_i(A + A^*) \leq 2\sigma_i(A)$, $i = 1, 2, \ldots, n$.

11. [LM02] (*Block triangular matrices*) Let $A = \begin{bmatrix} R & 0 \\ S & T \end{bmatrix} \in \mathbb{C}^{n\times n}$ ($R \in \mathbb{C}^{p\times p}$) have singular values $\alpha_1 \geq \cdots \geq \alpha_n$. Let $k = \min\{p, n-p\}$. Then

(a) If $\sigma_{\min}(R) \geq \sigma_{\max}(T)$, then

$$\begin{aligned} \sigma_i(R) &\leq \alpha_i, \quad i = 1, \ldots, p \\ \alpha_i &\leq \sigma_{i-p}(T), \quad i = p+1, \ldots, n. \end{aligned}$$

(b) $(\sigma_1(S), \ldots, \sigma_k(S)) \preceq_w (\alpha_1 - \alpha_n, \cdots, \alpha_k - \alpha_{n-k+1})$.

(c) If A is invertible, then

$$(\sigma_1(T^{-1}SR^{-1}, \ldots, \sigma_k(T^{-1}SR^{-1}) \preceq_w \left(\alpha_n^{-1} - \alpha_1^{-1}, \cdots, \alpha_{n-k+1}^{-1} - \alpha_k^{-1}\right),$$

$$(\sigma_1(T^{-1}S), \ldots, \sigma_k(T^{-1}S)) \preceq_w \frac{1}{2}\left(\frac{\alpha_1}{\alpha_n} - \frac{\alpha_n}{\alpha_1}, \cdots, \frac{\alpha_k}{\alpha_{n-k+1}} - \frac{\alpha_{n-k+1}}{\alpha_k}\right).$$

12. [LM02] (*Block positive semidefinite matrices*) Let $A = \begin{bmatrix} A_{11} A_{12} \\ A_{12}^* A_{22} \end{bmatrix} \in \mathbb{C}^{n\times n}$ be positive definite with eigenvalues $\lambda_1 \geq \cdots \geq \lambda_n$. Assume $A_{11} \in \mathbb{C}^{p\times p}$. Set $k = \min\{p, n-p\}$. Then

$$\prod_{i=1}^{j} \sigma_i^2(A_{12}) \leq \prod_{i=1}^{j} \sigma_i(A_{11})\sigma_i(A_{22}), \quad j = 1, \ldots, k,$$

$$\left(\sigma_1(A_{11}^{-1/2}A_{12}), \ldots, \sigma_k(A_{11}^{-1/2}A_{12})\right) \preceq_w \left(\sqrt{\lambda_1} - \sqrt{\lambda_n}, \ldots, \sqrt{\lambda_k} - \sqrt{\lambda_{n-k+1}}\right),$$

$$\left(\sigma_1(A_{11}^{-1}A_{12}), \ldots, \sigma_k(A_{11}^{-1}A_{12})\right) \preceq_w \frac{1}{2}\left(\chi(\lambda_1, \lambda_n), \ldots, \chi(\lambda_k, \lambda_{n-k+1})\right).$$

If $k = n/2$, then

$$\|A_{12}\|_{UI}^2 \leq \|A_{11}\|_{UI}\, \|A_{22}\|_{UI}.$$

13. (*Singular values and eigenvalues*) Let $A \in \mathbb{C}^{n\times n}$. Assume $|\lambda_1(A)| \geq \cdots \geq |\lambda_n(A)|$. Then
    (a) $\prod_{i=1}^k |\lambda_i(A)| \leq \prod_{i=k}^k \sigma_i(A), \quad k = 1, \ldots, n$, with equality for $k = n$.
    (b) Fix $p > 0$. Then for $k = 1, 2, \ldots, n$,
    $$\sum_{i=1}^k |\lambda_i^p(A)| \leq \sum_{i=1}^k \sigma_i^p(A).$$
    Equality holds with $k = n$ if and only if equality holds for all $k = 1, 2, \ldots, n$, if and only if A is normal.
    (c) [HJ91, p. 180] (Yamamoto's theorem) $\lim_{k\to\infty}(\sigma_i(A^k))^{1/k} = |\lambda_i(A)|, i = 1, \ldots, n$.
14. [LM01] Let $\lambda_i \in \mathbb{C}$ and $\sigma_i \in \mathbb{R}_0^+$, $i = 1, \ldots, n$ be ordered in nonincreasing absolute value. There is a matrix A with eigenvalues $\lambda_1, \ldots, \lambda_n$ and singular values $\sigma_1, \ldots, \sigma_n$ if and only if
    $$\prod_{i=1}^k |\lambda_i| \leq \prod_{i=1}^k \sigma_i, \quad k = 1, \ldots, n, \quad \text{with equality for } k = n.$$
    In addition:
    (a) The matrix A can be taken to be upper triangular with the eigenvalues on the diagonal in any order.
    (b) If the complex entries in $\lambda_1, \ldots, \lambda_n$ occur in conjugate pairs, then A may be taken to be in real Schur form, with the 1×1 and 2×2 blocks on the diagonal in any order.
    (c) There is a finite construction of the upper triangular matrix in cases (a) and (b).
    (d) If $n > 2$, then A cannot always be taken to be bidiagonal. (Example 5)
15. [Zha02, Chap. 2] (*Singular values of* $A \circ B$) Take $A, B \in \mathbb{C}^{n\times n}$.
    (a) $\sigma_i(A \circ B) \leq \min\{r_i(A), c_i(B)\} \cdot \sigma_1(B), \quad i = 1, 2, \ldots, n$.
    (b) We have the following weak majorizations:
    $$\begin{aligned} \sum_{i=1}^k \sigma_i(A \circ B) &\leq \sum_{i=1}^k \min\{r_i(A), c_i(A)\}\sigma_i(B), \quad k = 1, \ldots, n, \\ \sum_{i=1}^k \sigma_i(A \circ B) &\leq \sum_{i=1}^k \sigma_i(A)\sigma_i(B), \quad k = 1, \ldots, n, \\ \prod_{i=1}^k \sigma_i^2(A \circ B) &\leq \prod_{i=1}^k \sigma_i((A^*A) \circ (B^*B)), \quad k = 1, \ldots, n. \end{aligned}$$
    (c) Take $X, Y \in \mathbb{C}^{n\times n}$. If $A = X^*Y$, then we have the weak majorization
    $$\sum_{i=1}^k \sigma_i(A \circ B) \leq \sum_{i=1}^k c_i(X)c_i(Y)\sigma_i(B), \quad k = 1, \ldots, n.$$

(d) If B is positive semidefinite with diagonal entries $b_{11} \geq \cdots \geq b_{nn}$, then

$$\sum_{i=1}^{k} \sigma_i(A \circ B) \leq \sum_{i=1}^{k} b_{ii}\sigma_i(A), \quad k = 1, \ldots, n.$$

(e) If both A and B are positive definite, then so is $A \circ B$ (Schur product theorem). In this case, the singular values of A, B and $A \circ B$ are their eigenvalues and BA has positive eigenvalues and we have the weak multiplicative majorizations

$$\prod_{i=k}^{n} \lambda_i(B)\lambda_i(A) \leq \prod_{i=k}^{n} b_{ii}\lambda_i(A) \leq \prod_{i=k}^{n} \lambda_i(BA) \leq \prod_{i=k}^{n} \lambda_i(A \circ B), \quad k = 1, 2, \ldots, n.$$

The inequalities are still valid if we replace $A \circ B$ by $A \circ B^T$. (Note B^T is not necessarily the same as $B^* = B$.)

16. Let $A \in \mathbb{C}^{m \times n}$. The following are equivalent:
    (a) $\sigma_1(A \circ B) \leq \sigma_1(B)$ for all $B \in \mathbb{C}^{m \times n}$.
    (b) $\sum_{i=1}^{k} \sigma_i(A \circ B) \leq \sum_{i=1}^{k} \sigma_i(B)$ for all $B \in \mathbb{C}^{m \times n}$ and all $k = 1, \ldots, q$.
    (c) There are positive semidefinite $P \in \mathbb{C}^{n \times n}$ and $Q \in \mathbb{C}^{m \times m}$ such that

$$\begin{bmatrix} P & A \\ A^* & Q \end{bmatrix}$$

is positive semidefinite, and has diagonal entries at most 1.

17. (*Singular values and matrix entries*) Take $A \in \mathbb{C}^{m \times n}$. Then

$$\begin{aligned} \left(|a_{11}|^2, |a_{12}|^2, \ldots, |a_{mn}|^2\right) &\preceq \left(\sigma_1^2(A), \ldots, \sigma_q^2(A), 0, \ldots, 0\right), \\ \sum_{i=1}^{q} \sigma_i^p(A) &\leq \sum_{i=1}^{m}\sum_{j=1}^{n} |a_{ij}|^p, \quad 0 \leq p \leq 2, \\ \sum_{i=1}^{m}\sum_{j=1}^{n} |a_{ij}|^p &\leq \sum_{i=1}^{q} \sigma_i^p(A), \quad 2 \leq p < \infty. \end{aligned}$$

If $\sigma_1(A) = |a_{ij}|$, then all the other entries in row i and column j of A are 0.

18. Take $\sigma_1 \geq \cdots \geq \sigma_n \geq 0$ and $\alpha_1 \geq \cdots \geq \alpha_n \geq 0$. Then

$$\exists A \in \mathbb{R}^{n \times n} \text{ s.t. } \sigma_i(A) = \sigma_i \quad \text{and} \quad c_i(A) = \alpha_i \quad \Leftrightarrow \quad \left(\alpha_1^2, \ldots, \alpha_n^2\right) \preceq \left(\sigma_1^2, \ldots, \sigma_n^2\right).$$

This statement is still true if we replace $\mathbb{R}^{n \times n}$ by $\mathbb{C}^{n \times n}$ and/or $c_i(\,\cdot\,)$ by $r_i(\,\cdot\,)$.

19. Take $A \in \mathbb{C}^{n \times n}$. Then

$$\prod_{i=k}^{n} \sigma_i(A) \leq \prod_{i=k}^{n} c_i(A), \quad k = 1, 2, \ldots, n.$$

The case $k = 1$ is Hadamard's Inequality: $|\det(A)| \leq \prod_{i=1}^{n} c_i(A)$.

20. [Tho77] Take $F = \mathbb{C}$ or $\mathbb{R}$ and $d_1, \ldots, d_n \in F$ such that $|d_1| \geq \cdots \geq |d_n|$, and $\sigma_1 \geq \cdots \geq \sigma_n \geq 0$. There is a matrix $A \in F^{n \times n}$ with diagonal entries $d_1, \ldots, d_n$ and singular values $\sigma_1, \ldots, \sigma_n$ if and only if

$$(|d_1|, \ldots, |d_n|) \preceq_w (\sigma_1(A), \ldots, \sigma_n(A)) \quad \text{and} \quad \sum_{j=1}^{n-1} |d_j| - |d_n| \leq \sum_{j=1}^{n-1} \sigma_j(A) - \sigma_n(A).$$

21. (*Nonnegative matrices*) Take $A = [a_{ij}] \in \mathbb{C}^{m\times n}$.
    (a) If $B = [|a_{ij}|]$, then $\sigma_1(A) \le \sigma_1(B)$.
    (b) If A and B are real and $0 \le a_{ij} \le b_{ij}\ \ \forall\ i, j$, then $\sigma_1(A) \le \sigma_1(B)$. The condition $0 \le a_{ij}$ is essential. (Example 4)
    (c) The condition $0 \le b_{ij} \le 1\ \ \forall\ i, j$ does not imply $\sigma_1(A \circ B) \le \sigma_1(A)$. (Example 4)
22. (*Bound on* σ_1) Let $A \in \mathbb{C}^{m\times n}$. Then $\|A\|_2 = \sigma_1(A) \le \sqrt{\|A\|_1\|A\|_\infty}$.
23. [Zha99] (*Cartesian decomposition*) Let $C = A + iB \in \mathbb{C}^{n\times n}$, where A and B are Hermitian. Let A, B, C have singular values $\alpha_j, \beta_j, \gamma_i$, $j = 1, \dots, n$. Then

$$(\gamma_1, \dots, \gamma_n) \preceq_w \sqrt{2}(|\alpha_1 + i\beta_1|, \dots, |\alpha_n + i\beta_n|) \preceq_w 2(\gamma_1, \dots, \gamma_n).$$

Examples:

1. Take

$$A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

   Then B is a pinching of A, and C is a pinching of both A and B. The matrices A, B, C have singular values $\alpha = (3, 0, 0)$, $\beta = (2, 1, 0)$, and $\gamma = (1, 1, 1)$. As stated in Fact 5, $\gamma \preceq_w \beta \preceq_w \alpha$. In fact, since the matrices are all positive semidefinite, we may replace $\preceq_w$ by $\preceq$. However, it is not true that $\gamma_i \le \alpha_i$ except for $i = 1$. Nor is it true that $|\det(C)| \le |\det(A)|$.
2. The matrices

$$A = \begin{bmatrix} 11 & -3 & -5 & 1 \\ 1 & -5 & -3 & 11 \\ -5 & 1 & 11 & -3 \\ -3 & 11 & 1 & -5 \end{bmatrix}, \quad B = \begin{bmatrix} 11 & -3 & -5 & 1 \\ 1 & -5 & -3 & 11 \\ -5 & 1 & 11 & -3 \end{bmatrix}, \quad C = \begin{bmatrix} 11 & -3 & -5 \\ 1 & -5 & -3 \\ -5 & 1 & 11 \end{bmatrix}$$

   have singular values $\alpha = (20, 12, 8, 4)$, $\beta = (17.9, 10.5, 6.0)$, and $\gamma = (16.7, 6.2, 4.5)$ (to 1 decimal place). The singular values of B interlace those of A ($\alpha_4 \le \beta_3 \le \alpha_3 \le \beta_2 \le \alpha_2 \le \beta_1 \le \alpha_1$), but those of C do not. In particular, $\alpha_3 \not\le \gamma_2$. It is true that $\alpha_{i+2} \le \gamma_i \le \alpha_i$ $(i = 1, 2)$.
3. Take

$$A = \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 0 & 1 \\ 0 & 1 \end{bmatrix}.$$

   Then $\|A + B\|_2 = \sigma_1(A + B) = 2 \not\le \sqrt{2} = \sigma_1(|A|_{pd} + |B|_{pd}) = \|\ |A|_{pd} + |B|_{pd}\ \|_2$. Also, $2\sigma_1(A^*B) = 4 \not\le 2 = \sigma_1(A^*A + B^*B)$.
4. Setting entries of a matrix to zero can increase the largest singular value. Take

$$A = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}.$$

   Then $\sigma_1(A) = \sqrt{2} < (1 + \sqrt{5})/2 = \sigma_1(B)$.
5. A bidiagonal matrix B cannot have eigenvalues 1, 1, 1 and singular values 1/2, 1/2, 4. If B is unreduced bidiagonal, then it cannot have repeated singular values. (See Fact 24.2.10.) However, if B were reduced, then it would have a singular value equal to 1.

24.5 Matrix Approximation

Recall that $\|\cdot\|_{UI}$ denotes a general unitarily invariant norm, and that $q = \min\{m, n\}$.

Facts:

The following facts can be found in standard references, for example, [HJ91, Chap. 3], unless another reference is given.

1. (*Best rank k approximation.*) Let $A \in \mathbb{C}^{m\times n}$ and $1 \le k \le q-1$. Let $A = U\Sigma V^*$ be a singular value decomposition of A. Let $\tilde{\Sigma}$ be equal to Σ except that $\tilde{\Sigma}_{ii} = 0$ for $i > k$, and let $\tilde{A} = U\tilde{\Sigma}V^*$. Then $\text{rank}(\tilde{A}) \le k$, and
$$\|\Sigma - \tilde{\Sigma}\|_{UI} = \|A - \tilde{A}\|_{UI} = \min\{\|A - B\|_{UI} : \text{rank}(B) \le k\}.$$
In particular, for the spectral norm and the Frobenius norm, we have
$$\begin{aligned} \sigma_{k+1}(A) &= \min\{\|A - B\|_2 : \text{rank}(B) \le k\}, \\ \left(\sum_{i=k+1}^{q} \sigma_{k+1}^2(A)\right)^{1/2} &= \min\{\|A - B\|_F : \text{rank}(B) \le k\}. \end{aligned}$$
2. [Bha97, p. 276] (*Best unitary approximation*) Take $A, W \in \mathbb{C}^{n\times n}$ with W unitary. Let $A = UP$ be a polar decomposition of A. Then
$$\|A - U\|_{UI} \le \|A - W\|_{UI} \le \|A + U\|_{UI}.$$
3. [GV96, §12.4.1], [HJ85, Ex. 7.4.8] (*Orthogonal Procrustes problem*) Let $A, B \in \mathbb{C}^{m\times n}$. Let B^*A have a polar decomposition $B^*A = UP$. Then
$$\|A - BU\|_F = \min\{\|A - BW\|_F : W \in \mathbb{C}^{n\times n}, W^*W = I\}.$$
This result is not true if $\|\cdot\|_F$ is replaced by $\|\cdot\|_{UI}$ ([Mat93, §4]).
4. [Hig89] (*Best PSD approximation*) Take $A \in \mathbb{C}^{n\times n}$. Set $A_H = (A + A^*)/2$, $B = (A_H + |A_H|)/2)$. Then B is positive semidefinite and is the unique solution to
$$\min\{\|A - X\|_F : X \in \mathbb{C}^{n\times n}, X \in \text{PSD}\}.$$
There is also a formula for the best PSD approximation in the spectral norm.
5. Let $A, B \in \mathbb{C}^{m\times n}$ have singular value decompositions $A = U_A\Sigma_A V_A^*$ and $B = U_B\Sigma_B V_B^*$. Let $U \in \mathbb{C}^{m\times m}$ and $V \in \mathbb{C}^{n\times n}$ be any unitary matrices. Then
$$\|\Sigma_A - \Sigma_B\|_{UI} \le \|A - UBV^*\|_{UI}.$$

24.6 Characterization of the Eigenvalues of Sums of Hermitian Matrices and Singular Values of Sums and Products of General Matrices

There are necessary and sufficient conditions for three sets of numbers to be the eigenvalues of Hermitian $A, B, C = A + B \in \mathbb{C}^{n\times n}$, or the singular values of $A, B, C = A + B \in \mathbb{C}^{m\times n}$, or the singular values of nonsingular $A,\ B,\ C = AB \in \mathbb{C}^{n\times n}$. The key results in this section were first proved by Klyachko [Kly98] and Knutson and Tao [KT99]. The results presented here are from a survey by Fulton [Ful00]. Bhatia has written an expository paper on the subject [Bha01].

Definitions:

The inequalities are in terms of the sets T_r^n of triples (I, J, K) of subsets of $\{1, \ldots, n\}$ of the same cardinality r, defined by the following inductive procedure. Set

$$U_r^n = \left\{ (I, J, K) \;\middle|\; \sum_{i \in I} i + \sum_{j \in J} j = \sum_{k \in K} k + r(r+1)/2 \right\}.$$

When $r = 1$, set $T_1^n = U_1^n$. In general,

$$T_r^n = \Bigg\{ (I, J, K) \in U_r^n \,|\, \mathrm{for\ \ all\ \ p < r\ \ and\ \ all}$$

$$(F, G, H)\ \ \mathrm{in}\ \ \mathrm{T_p^r}, \sum_{\mathrm{f \in F}} \mathrm{i_f} + \sum_{\mathrm{g \in G}} \mathrm{j_g} \leq \sum_{\mathrm{h \in H}} \mathrm{k_h} + \mathrm{p(p+1)/2} \Bigg\}.$$

In this section, the vectors α, β, γ will have real entries ordered in nonincreasing order.

Facts:

The following facts are in [Ful00]:

1. A triple (α, β, γ) of real n-vectors occurs as eigenvalues of Hermitian A, B, $C = A + B \in \mathbb{C}^{n \times n}$ if and only if $\sum \gamma_i = \sum \alpha_i + \sum \beta_i$ and the inequalities
$$\sum_{k \in K} \gamma_k \;\leq\; \sum_{i \in I} \alpha_i + \sum_{j \in J} \beta_j$$
hold for every (I, J, K) in T_r^n, for all $r < n$. Furthermore, the statement is true if $\mathbb{C}^{n \times n}$ is replaced by $\mathbb{R}^{n \times n}$.
2. Take Hermitian $A, B \in \mathbb{C}^{n \times n}$ (not necessarily PSD). Let the vectors of eigenvalues of A, B, $C = A + B$ be α, β, and γ. Then we have the (nonlinear) inequality
$$\min_{\pi \in S_n} \prod_{i=1}^{n} (\alpha_i + \beta_{\pi(i)}) \;\leq\; \prod_{i=1}^{n} \gamma_i \;\leq\; \max_{\pi \in S_n} \prod_{i=1}^{n} (\alpha_i + \beta_{\pi(i)}).$$
3. Fix m, n and set $q = \min\{m, n\}$. For any subset X of $\{1, \ldots, m+n\}$, define $X_q = \{i : i \in X, i \leq q\}$ and $X'_q = \{i : i \leq q,\ m + n + 1 - i \in X\}$. A triple (α, β, γ) occurs as the singular values of $A, B, C = A + B \in \mathbb{C}^{m \times n}$, if and only if the inequalities
$$\sum_{k \in K_q} \gamma_k - \sum_{k \in K'_q} \gamma_k \;\leq\; \sum_{i \in I} \alpha_i - \sum_{i \in I'_q} \alpha_i + \sum_{j \in J_q} \beta_j - \sum_{j \in J'_q} \beta_j$$
are satisfied for all (I, J, K) in T_r^{m+n}, for all $r < m + n$. This statement is not true if $\mathbb{C}^{m \times n}$ is replaced by $\mathbb{R}^{m \times n}$. (See Example 1.)
4. A triple of positive real n-vectors (α, β, γ) occurs as the singular values of n by n matrices A,B, $C = AB \in \mathbb{C}^{n \times n}$ if and only if $\gamma_1 \cdots \gamma_n = \alpha_1 \cdots \alpha_n \beta_1 \cdots \beta_n$ and
$$\prod_{k \in K} \gamma_k \leq \prod_{i \in I} \alpha_i \cdot \prod_{j \in J} \beta_j$$
for all (I, J, K) in T_r^n, and all $r < n$. This statement is still true if $\mathbb{C}^{n \times n}$ is replaced by $\mathbb{R}^{n \times n}$.

Example:

1. There are $A, B, C = A + B \in \mathbb{C}^{2 \times 2}$ with singular values $(1, 1)$, $(1, 0)$, and $(1, 1)$, but there are no $A, B, C = A + B \in \mathbb{R}^{2 \times 2}$ with these singular values.

In the complex case, take $A = \text{diag}(1, 1/2 + (\sqrt{3}/2)i)$, $B = \text{diag}(0, -1)$.

Now suppose that A and B are real 2×2 matrices such that A and $C = A + B$ both have singular values $(1, 1)$. Then A and C are orthogonal. Consider $BC^T = AC^T - CC^T = AC^T - I$. Because AC^T is real, it has eigenvalues $\alpha, \bar{\alpha}$ and so BC^T has eigenvalues $\alpha - 1$, $\bar{\alpha} - 1$. Because AC^T is orthogonal, it is normal and, hence, so is BC^T, and so its singular values are $|\alpha - 1|$ and $|\bar{\alpha} - 1|$, which are equal and, in particular, cannot be $(1, 0)$.

24.7 Miscellaneous Results and Generalizations

Throughout this section F can be taken to be either $\mathbb{R}$ or $\mathbb{C}$.

Definitions:

Let $\mathcal{X}$, $\mathcal{Y}$ be subspaces of $\mathbb{C}^r$ of dimension m and n. The **principal angles** $0 \leq \theta_1 \leq \cdots \leq \theta_q \leq \pi/2$ between $\mathcal{X}$ and $\mathcal{Y}$ and **principal vectors** $\mathbf{u}_1, \ldots, \mathbf{u}_q$ and $\mathbf{v}_1, \ldots, \mathbf{v}_q$ are defined inductively:

$$\cos(\theta_1) = \max\{|\mathbf{x}^*\mathbf{y}| : \mathbf{x} \in \mathcal{X}, \max_{\mathbf{y} \in \mathcal{Y}}, \|\mathbf{x}\|_2 = \|\mathbf{y}\|_2 = 1\}.$$

Let $\mathbf{u}_1$ and $\mathbf{v}_1$ be a pair of maximizing vectors. For $k = 2, \ldots, q$,

$$\cos(\theta_k) = \max\{|\mathbf{x}^*\mathbf{y}| : \mathbf{x} \in \mathcal{X}, \mathbf{y} \in \mathcal{Y}, \|\mathbf{x}\|_2 = \|\mathbf{y}\|_2 = 1, \quad \mathbf{x}^*\mathbf{u}_i = \mathbf{y}^*\mathbf{v}_i = 0, \quad i = 1, \ldots, k-1\}.$$

Let $\mathbf{u}_k$ and $\mathbf{v}_k$ be a pair of maximizing vectors. (Principal angles are also called **canonical angles**, and the cosines of the principal angles are called **canonical correlations**.)

Facts:

1. (*Principal Angles*) Let $\mathcal{X}$, $\mathcal{Y}$ be subspaces of $\mathbb{C}^r$ of dimension m and n.

   (a) [BG73] The principal vectors obtained by the process above are not necessarily unique, but the principal angles are unique (and, hence, independent of the chosen principal vectors).

   (b) Let $m = n \leq r/2$ and X, Y be matrices whose columns form orthonormal bases for the subspaces $\mathcal{X}$ and $\mathcal{Y}$, respectively.

      i. The singular values of X^*Y are the cosines of the principal angles between the subspaces $\mathcal{X}$ and $\mathcal{Y}$.

      ii. There are unitary matrices $U \in \mathbb{C}^{r \times r}$ and V_X and $V_Y \in \mathbb{C}^{n \times n}$ such that

$$UXV_X = \begin{bmatrix} I_n \\ 0_n \\ 0_{r-n,n} \end{bmatrix}, \quad UYV_Y = \begin{bmatrix} \Gamma \\ \Sigma \\ 0_{r-n,n} \end{bmatrix},$$

      where Γ and Σ are nonnegative diagonal matrices. Their diagonal entries are the cosines and sines, respectively, of the principal angles between $\mathcal{X}$ and $\mathcal{Y}$.

   (c) [QZL05] Take $m = n$. For any permutation invariant absolute norm g on $\mathbb{R}^m$,

$$g(\sin(\theta_1), \ldots, \sin(\theta_m)), \quad g(2\sin(\theta_1/2), \ldots, 2\sin(\theta_m/2)), \quad \text{and} \quad g(\theta_1, \ldots, \theta_m)$$

   are metrics on the set of subspaces of dimension n of $\mathbb{C}^{r \times r}$.

2. [GV96, Theorem 2.6.2] (*CS decomposition*) Let $W \in F^{n\times n}$ be unitary. Take a positive integer l such that $2l \leq n$. Then there are unitary matrices $U_{11}, V_{11} \in F^{l\times l}$ and $U_{22}, V_{22} \in F^{(n-l)\times(n-l)}$ such that

$$\begin{bmatrix} U_{11} & 0 \\ 0 & U_{22} \end{bmatrix} W \begin{bmatrix} V_{11} & 0 \\ 0 & V_{22} \end{bmatrix} = \begin{bmatrix} \Gamma & -\Sigma & 0 \\ \Sigma & \Gamma & 0 \\ 0 & 0 & I_{n-2l} \end{bmatrix},$$

   where $\Gamma = \operatorname{diag}(\gamma_1, \ldots, \gamma_l)$ and $\Sigma = \operatorname{diag}(\sigma_1, \ldots, \sigma_l)$ are nonnegative and $\Gamma^2 + \Sigma^2 = I$.

3. [GV96, Theorem 8.7.4] (*Generalized singular value decomposition*) Take $A \in F^{p\times n}$ and $B \in F^{m\times n}$ with $p \geq n$. Then there is an invertible $X \in F^{n\times n}$, unitary $U \in F^{p\times p}$ and $V \in F^{m\times m}$, and nonnegative diagonal matrices $\Sigma_A \in \mathbb{R}^{n\times n}$ and $\Sigma_B \in \mathbb{R}^{q\times q}$ ($q = \min\{m, n\}$) such that $A = U\Sigma_A X$ and $B = V\Sigma_B X$.

The numerical range $W(A)$ of an $n \times n$ complex matrix A is the collection of complex numbers of the form $\mathbf{x}^*A\mathbf{x}$, where $\mathbf{x} \in \mathbb{C}^n$ is a unit vector. It can be viewed as a "picture" of A containing useful information of A. Even if the matrix A is not known explicitly, the "picture" $W(A)$ would allow one to "see" many properties of the matrix. For example, the numerical range can be used to locate eigenvalues, deduce algebraic and analytic properties, obtain norm bounds, help find dilations with simple structure, etc. Related to the numerical range are the numerical radius of A defined by $w(A) = \max_{\mu \in W(A)} |\mu|$ and the distance of $W(A)$ to the origin denoted by $\widetilde{w}(A) = \min_{\mu \in W(A)} |\mu|$. If $0 \notin W(A)$, the value $\tilde{w}(A)$ is also known as the Crawford number of A. The quantities $w(A)$ and $\widetilde{w}(A)$ are useful in studying perturbation, convergence, stability, and approximation problems.

Note that the spectrum $\sigma(A)$ can be viewed as another useful "picture" of the matrix $A \in M_n$. There are interesting relations between $\sigma(A)$ and $W(A)$.

25.1 Basic Properties and Examples

Definitions:

Let $A \in \mathbb{C}^{n \times n}$.

The **numerical range** (also known as **the field of values**) of A is defined by

$$W(A) = \{\mathbf{x}^*A\mathbf{x} : \mathbf{x} \in \mathbb{C}^n, \mathbf{x}^*\mathbf{x} = 1\}.$$

The **numerical radius** of A and the **distance** of $W(A)$ to the origin are the quantities

$$w(A) = \max\{|\mu| : \mu \in W(A)\} \quad \text{and} \quad \widetilde{w}(A) = \min\{|\mu| : \mu \in W(A)\}.$$

Furthermore, let

$$\overline{W(A)} = \{\overline{a} : a \in W(A)\}.$$

Facts:

The following basic facts can be found in most references on numerical ranges such as [GR96], [Hal82], [HJ91, Chap. 1].

1. Let $A \in \mathbb{C}^{n\times n}$, $a, b \in \mathbb{C}$. Then $W(aA + bI) = aW(A) + b$.
2. Let $A \in \mathbb{C}^{n\times n}$. Then $W(U^*AU) = W(A)$ for any unitary $U \in \mathbb{C}^{n\times n}$.
3. Let $A \in \mathbb{C}^{n\times n}$. Suppose $k \in \{1, \dots, n-1\}$ and $X \in \mathbb{C}^{n\times k}$ satisfies $X^*X = I_k$. Then
$$W(X^*AX) \subseteq W(A).$$
In particular, for any $k \times k$ principal submatrix B of A, we have $W(B) \subseteq W(A)$.
4. Let $A \in \mathbb{C}^{n\times n}$. Then $W(A)$ is a compact convex set in $\mathbb{C}$.
5. If $A_1 \oplus A_2 \in M_n$, then $W(A) = \operatorname{conv}\{W(A_1) \cup W(A_2)\}$.
6. Let $A \in M_n$. Then $W(A) = W(A^T)$ and $W(A^*) = \overline{W(A)}$.
7. If $A \in \mathbb{C}^{2\times 2}$ has eigenvalues λ_1, λ_2 then $W(A)$ is an elliptical disk with foci λ_1, λ_2 and minor axis with length $\{\operatorname{tr}(A^*A) - |\lambda_1|^2 - |\lambda_2|^2\}^{1/2}$. Consequently, if $A = \begin{bmatrix} \lambda_1 & b \\ 0 & \lambda_2 \end{bmatrix}$, then the minor axis of the elliptical disk $W(A)$ has length $|b|$.
8. Let $A \in \mathbb{C}^{n\times n}$. Then $W(A)$ is a subset of a straight line if and only if there are $a, b \in \mathbb{C}$ with $a \neq 0$ such that $aA + bI$ is Hermitian. In particular, we have the following.
   (a) $A = aI$ if and only if $W(A) = \{a\}$.
   (b) $A = A^*$ if and only if $W(A) \subseteq \mathbb{R}$.
   (c) $A = A^*$ is positive definite if and only if $W(A) \subseteq (0, \infty)$.
   (d) $A = A^*$ is positive semidefinite if and only if $W(A) \subseteq [0, \infty)$.
9. If $A \in \mathbb{C}^{n\times n}$ is normal, then $W(A) = \operatorname{conv}\sigma(A)$ is a convex polygon. The converse is true if $n \leq 4$.
10. Let $A \in \mathbb{C}^{n\times n}$. The following conditions are equivalent.
    (a) $W(A) = \operatorname{conv}\sigma(A)$.
    (b) $W(A)$ is a convex polygon with vertices $\mu_1, \dots, \mu_k$.
    (c) A is unitarily similar to $\operatorname{diag}(\mu_1, \dots, \mu_k) \oplus B$ such that $W(B) \subseteq \operatorname{conv}\{\mu_1, \dots, \mu_k\}$.
11. Let $A \in \mathbb{C}^{n\times n}$. Then A is unitary if and only if all eigenvalues of A have modulus one and $W(A) = \operatorname{conv}\sigma(A)$.
12. Suppose $A = (A_{ij})_{1\leq i,j\leq m} \in M_n$ is a block matrix such that $A_{11}, \dots, A_{mm}$ are square matrices and $A_{ij} = 0$ whenever $(i, j) \notin \{(1, 2), \dots, (m-1, m), (m, 1)\}$. Then $W(A) = cW(A)$ for any $c \in \mathbb{C}$ satisfying $c^m = 1$. If $A_{m,1}$ is also zero, then $W(A)$ is a circular disk centered at 0 with the radius equal to the largest eigenvalue of $(A + A^*)/2$.

Examples:

1. Let $A = \operatorname{diag}(1, 0)$. Then $W(A) = [0, 1]$.
2. Let $A = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$. Then $W(A)$ is the closed unit disk $\mathbf{D} = \{a \in \mathbb{C} : |a| \leq 1\}$.
3. Let $A = \begin{bmatrix} 1.5 & 2 \\ 0 & 0.5 \end{bmatrix}$. Then by Fact 7, $W(A)$ is the convex set whose boundary is the ellipse with foci 0.5 and 1.5 and minor axis 2, as shown in Figure 25.1.
4. Let $A = \operatorname{diag}(1, i, -1, -i) \oplus \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$. By Facts 5 and 7, the boundary of $W(A)$ is the square with vertices $1, i, -1, -i$.

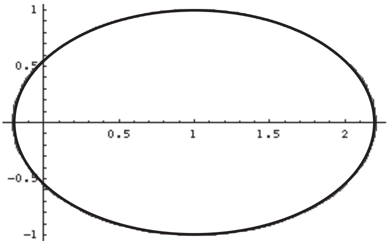

FIGURE 25.1 Numerical range of the matrix A in Example 3.

Applications:

1. By Fact 6, if A is real, then $W(A)$ is symmetric about the real axis, i.e., $W(A) = \overline{W(A)}$.
2. Suppose $A \in \mathbb{C}^{n\times n}$, and there are $a, b \in \mathbb{C}$ such that $(A - aI)(A - bI) = 0_n$. Then A is unitarily similar to a matrix of the form
$$aI_r \oplus bI_s \oplus \begin{bmatrix} a & d_1 \\ 0 & b \end{bmatrix} \oplus \cdots \oplus \begin{bmatrix} a & d_t \\ 0 & b \end{bmatrix}$$
with $d_1 \geq \cdots \geq d_t > 0$, where $r + s + 2t = n$. By Facts 1, 5, and 7, the set $W(A)$ is the elliptical disk with foci a, b and minor axis of length d, where $d = d_1$ if $t \geq 1$, and $d = 0$ otherwise.
3. By Fact 12, if $A \in M_n$ is the Jordan block of zero $J_n(0)$, then $W(A) = \{c \in \mathbb{C} : |c| \leq \cos(\pi/(n+1))\}$; if $A \in \mathbb{C}^{n\times n}$ is the basic circulant matrix $E_{12} + E_{23} + \cdots + E_{n-1,n} + E_{n1}$, then $W(A) = \operatorname{conv}\{c \in \mathbb{C} : c^n = 1\}$.
4. Suppose $A \in \mathbb{C}^{n\times n}$ is a primitive nonnegative matrix. Then A is permutationally similar to a block matrix (A_{ij}) as described in Fact 12, and thus, $W(A) = cW(A)$ for any $c \in \mathbb{C}$ satisfying $c^m = 1$.

25.2 The Spectrum and Special Boundary Points

Definitions:

Let $\partial\mathcal{S}$ and $\operatorname{int}(\mathcal{S})$ be the boundary and the interior of a convex compact subset $\mathcal{S}$ of $\mathbb{C}$.

A **support line** ℓ of $\mathcal{S}$ is a line that intersects $\partial\mathcal{S}$ such that $\mathcal{S}$ lies entirely within one of the closed half-planes determined by ℓ.

A boundary point μ of $\mathcal{S}$ is **non-differentiable** if there is more than one support line of $\mathcal{S}$ passing through μ.

An eigenvalue λ of $A \in \mathbb{C}^{n\times n}$ is a **reducing eigenvalue** if A is unitarily similar to $[\lambda] \oplus A_2$.

Facts:

The following facts can be found in [GR96], [Hal82], [HJ91, Chap. 1].

1. Let $A \in \mathbb{C}^{n\times n}$. Then
$$\sigma(A) \subseteq W(A) \subseteq \{a \in \mathbb{C} : |a| \leq \|A\|_2\}.$$
2. Let $A, E \in \mathbb{C}^{n\times n}$. We have
$$\begin{aligned}\sigma(A+E) &\subseteq W(A+E) \subseteq W(A) + W(E) \\ &\subseteq \{a + b \in \mathbb{C} : a \in W(A), b \in \mathbb{C} \text{ with } |b| \leq \|E\|_2\}.\end{aligned}$$

3. Let $A \in \mathbb{C}^{n\times n}$ and $a \in \mathbb{C}$. Then $a \in \sigma(A) \cap \partial W(A)$ if and only if A is unitarily similar to $aI_k \oplus B$ such that $a \notin \sigma(B) \cup \operatorname{int}(W(B))$.
4. Let $A \in \mathbb{C}^{n\times n}$ and $a \in \mathbb{C}$. Then a is a non-differentiable boundary point of $W(A)$ if and only if A is unitarily similar to $aI_k \oplus B$ such that $a \notin W(B)$. In particular, a is a reducing eigenvalue of A.
5. Let $A \in \mathbb{C}^{n\times n}$. If $W(A)$ has at least $n-1$ non-differentiable boundary points or if at least $n-1$ eigenvalues of A (counting multiplicities) lie in $\partial W(A)$, then A is normal.

Examples:

1. Let $A = [1] \oplus \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$. Then $W(A)$ is the unit disk centered at the origin, and 1 is a reducing eigenvalue of A lying on the boundary of $W(A)$.
2. Let $A = [2] \oplus \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$. Then $W(A)$ is the convex hull of unit disk centered at the origin the number 2, and 2 is a non-differentiable boundary point of $W(A)$.

Applications:

1. By Fact 1, if $A \in \mathbb{C}^{n\times n}$ and $0 \notin W(A)$, then $0 \notin \sigma(A)$, and thus A is invertible.
2. By Fact 4, if $A \in \mathbb{C}^{n\times n}$, then $W(A)$ has at most n non-differentiable boundary points.
3. While $W(A)$ does not give a very tight containment region for $\sigma(A)$ as shown in the examples in the previous section. Fact 2 shows that the numerical range can be used to estimate the spectrum of the resulting matrix when A is under a perturbation E. In contrast, $\sigma(A)$ and $\sigma(E)$ usually do not carry much information about $\sigma(A+E)$ in general. For example, let $A = \begin{bmatrix} 0 & M \\ 0 & 0 \end{bmatrix}$ and $E = \begin{bmatrix} 0 & 0 \\ \varepsilon & 0 \end{bmatrix}$. Then $\sigma(A) = \sigma(E) = \{0\}$, $\sigma(A+E) = \{\pm\sqrt{M\varepsilon}\} \subseteq W(A+E)$, which is the elliptical disk with foci $\pm\sqrt{M\varepsilon}$ and length of minor axis equal to $|\,|M| - |\varepsilon|\,|$. on a complex polynomial $p(z)$ asserts
4. The Lucas theorem asserts that if a complex polynomial has zeros $\mu_1, \ldots, \mu_n$, then the zeros of the derivative $p'(z)$ lie in $\operatorname{conv}\{\mu_1, \ldots, \mu_n\}$. This can be proved readily using the theory of the numerical range as follows. Let $A = FDF^*$, where D is the diagonal matrix $\sum_{j=1}^n \mu_j E_{jj}$ and $F = n^{-1/2}(w^{(i-1)(j-1)})_{1\le i,j\le n}$ with $w = e^{i2\pi/n}$. Suppose $\tilde{A}$ is obtained from A by removing its first row and the first column. Then the $(1,1)$ entry of $(zI-A)^{-1} = F(zI-D)^{-1}F^*$ equals $n^{-1}\sum_{j=1}^n (z-\mu_j)^{-1}$, and by the adjoint formula,

$$\det(zI-B) = \det(zI-A)[n^{-1}\sum_{j=1}^{n}(z-\mu_j)^{-1}] = \prod_{j=1}^{n}(z-\mu_j)[n^{-1}\sum_{j=1}^{n}(z-\mu_j)^{-1}] = n^{-1}p'(z).$$

Thus, the zeros of $p'(z)$ are the eigenvalues of B. By Facts 25.2.1, 25.1.3, and 25.1.9, we have

$$\sigma(B) \subseteq W(B) \subseteq W(A) = \operatorname{conv}\{\mu_1, \ldots, \mu_n\}.$$

25.3 Location of the Numerical Range

Facts:

The following facts can be found in [HJ91, Chap. 1].

1. Let $A \in \mathbb{C}^{n\times n}$ and $t \in [0, 2\pi)$. Suppose $\mathbf{x}_t \in \mathbb{C}^n$ is a unit eigenvector corresponding to the largest eigenvalue $\lambda_1(t)$ of $e^{it}A + e^{-it}A^*$, and

$$\mathcal{P}_t = \{a \in \mathbb{C} : e^{it}a + e^{-it}\bar{a} \le \lambda_1(t)\}.$$

Then

$$e^{it}W(A) \subseteq \mathcal{P}_t, \quad \lambda_t = \mathbf{x}_t^* A\mathbf{x}_t \in \partial W(A) \cap \partial \mathcal{P}_t,$$

and

$$W(A) = \cap_{r\in[0,2\pi)}\, e^{-ir}\mathcal{P}_r = \operatorname{conv}\{\lambda_r : r \in [0, 2\pi)\}.$$

If $T = \{t_1, \ldots, t_k\}$ with $0 \le t_1 < \cdots < t_k < 2\pi$ and $k > 2$ such that $t_k - t_1 > \pi$, then

$$P_T^O(A) = \cap_{r\in T}\, e^{-ir}P_r \qquad \text{and} \qquad P_T^I(A) = \operatorname{conv}\{\lambda_r : r \in T\}$$

are two polygons in $\mathbb{C}$ such that

$$P_T^I(A) \subseteq W(A) \subseteq P_T^O(A).$$

Moreover, both the area $W(A) \setminus P_T^I(A)$ and the area of $P_T^O(A) \setminus W(A)$ converge to 0 as $\max\{t_j - t_{j-1} : 1 \le j \le k+1\}$ converges to 0, where $t_0 = 0, t_{k+1} = 2\pi$.

2. Let $A = (a_{ij}) \in \mathbb{C}^{n\times n}$. For each $j = 1, \ldots, n$, let

$$g_j = \sum_{i\ne j}(|a_{ij}| + |a_{ji}|)/2 \quad \text{and} \quad G_j(A) = \{a \in \mathbb{C} : |a - a_{jj}| \le g_j\}.$$

Then

$$W(A) \subseteq \operatorname{conv} \cup_{j=1}^n G_j(A).$$

Examples:

1. Let $A = \begin{bmatrix} 2 & 2 \\ 0 & 2 \end{bmatrix}$. Then $W(A)$ is the circular disk centered at 2 with radius 1. In Figure 25.2, $W(A)$ is approximated by $P_T^O(A)$ with $T = \{2k\pi/100 : 0 \le k \le 99\}$. If $T = \{0, \pi/2, \pi, 3\pi/2\}$, then the polygon $P_T^O(A)$ in Fact 1 is bounded by the four lines $\{3+bi : b \in \mathbb{R}\}$, $\{a+i : a \in \mathbb{R}\}$, $\{1 + bi : b \in \mathbb{R}\}$, $\{a - i : a \in \mathbb{R}\}$, and the polygon $P_T^I(A)$ equals the convex hull of $\{3, 2+i, 1, 2-i\}$.

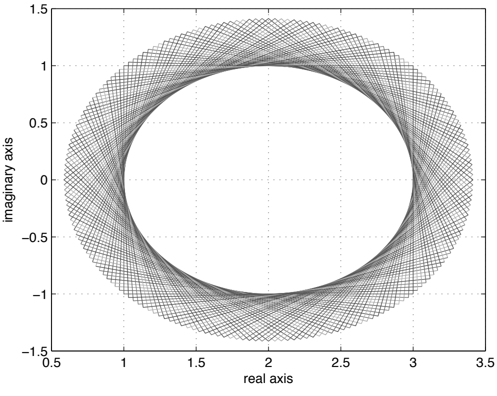

FIGURE 25.2 Numerical range of the matrix A in Example 1.

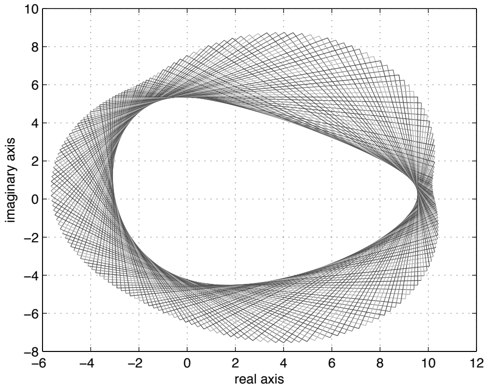

FIGURE 25.3 Numerical range of the matrix A in Example 2.

2. Let $A = \begin{bmatrix} 5i & 2 & 3 \\ 4 & -3i & -2 \\ 1 & 3 & 9 \end{bmatrix}$. In Figure 3, $W(A)$ is approximated by $P_T^O(A)$ with $T = \{2k\pi/100 : 0 \le k \le 99\}$. By Fact 2, $W(A)$ lies in the convex hull of the circles $G_1 = \{a \in \mathbb{C} : |a - 5i| \le 5\}$, $G_2 = \{a \in \mathbb{C} : |a + 3i| \le 5.5\}$, $G_3 = \{a \in \mathbb{C} : |a - 9| \le 4.5\}$.

Applications:

1. Let $A = H + iG$ where $H, G \in \mathbb{C}^{n\times n}$ are Hermitian. Then

$$W(A) \subseteq W(H) + iW(G) = \{a + ib : a \in W(H),\ b \in W(G)\},$$

which is $P_T^O(A)$ for $T = \{0, \pi/2, \pi, 3\pi/2\}$.

2. Let $A = H + iG$, where $H, G \in \mathbb{C}^{n\times n}$ are Hermitian. Denote by $\lambda_1(X) \ge \cdots \ge \lambda_n(X)$ for a Hermitian matrix $X \in \mathbb{C}^{n\times n}$. By Fact 1,

$$w(A) = \max\{\lambda_1(\cos tH + \sin tG) : t \in [0, 2\pi)\}.$$

If $0 \notin W(A)$, then

$$\widetilde{w}(A) = \max\{\{\lambda_n(\cos tH + \sin tG) : t \in [0, 2\pi)\} \cup \{0\}\}.$$

3. By Fact 2, if $A = (a_{ij}) \in \mathbb{C}^{n\times n}$, then

$$w(A) \le \max\{|a_{jj}| + g_j : 1 \le j \le n\}.$$

In particular, if A is nonnegative, then $w(A) = \lambda_1(A + A^T)/2$.

25.4 Numerical Radius

Definitions:

Let N be a vector norm on $\mathbb{C}^{n\times n}$.

It is **sub-multiplicative** if

$$N(AB) \le N(A)N(B) \quad \text{for all } A, B \in \mathbb{C}^{n\times n}.$$

It is **unitarily invariant** if

$$N(UAV) = N(A) \quad \text{for all } A \in \mathbb{C}^{n\times n} \text{ and unitary } U, V \in \mathbb{C}^{n\times n}.$$

It is **unitary similarity invariant** (also known as **weakly unitarily invariant**) if

$$N(U^*AU) = N(A) \quad \text{for all } A \in \mathbb{C}^{n\times n} \text{ and unitary } U \in \mathbb{C}^{n\times n}.$$

Facts:

The following facts can be found in [GR96], [Hal82], [HJ91, Chap. 1].

1. The numerical radius $w(\cdot)$ is a unitary similarity invariant vector norm on $\mathbb{C}^{n\times n}$, and it is not unitarily invariant.
2. For any $A \in \mathbb{C}^{n\times n}$, we have
$$\rho(A) \leq w(A) \leq \|A\|_2 \leq 2w(A).$$
3. Suppose $A \in \mathbb{C}^{n\times n}$ be nonzero and the minimal polynomial of A has degree m. The following conditions are equivalent.
   (a) $\rho(A) = w(A)$.
   (b) There exists $k \geq 1$ such that A is unitarily similar to $\gamma U \oplus B$ for a unitary $U \in \mathbb{C}^{k\times k}$ and $B \in \mathbb{C}^{(n-k)\times(n-k)}$ with $w(B) \leq w(A) = \gamma$.
   (c) There exists $s \geq m$ such that $w(A^s) = w(A)^s$.
4. Suppose $A \in \mathbb{C}^{n\times n}$ be nonzero and the minimal polynomial of A has degree m. The following conditions are equivalent.
   (a) $\rho(A) = \|A\|_2$.
   (b) $w(A) = \|A\|_2$.
   (c) There exists $k \geq 1$ such that A is unitarily similar to $\gamma U \oplus B$ for a unitary $U \in \mathbb{C}^{k\times k}$ and a $B \in \mathbb{C}^{(n-k)\times(n-k)}$ with $\|B\|_2 \leq \|A\|_2 = \gamma$.
   (d) There exists $s \geq m$ such that $\|A^s\|_2 = \|A\|_2^s$.
5. Suppose $A \in \mathbb{C}^{n\times n}$ is nonzero. The following conditions are equivalent.
   (a) $\|A\|_2 = 2w(A)$.
   (b) $W(A)$ is a circular disk centered at origin with radius $\|A\|_2/2$.
   (c) $A/\|A\|_2$ is unitarily similar to $A_1 \oplus A_2$ such that $A_1 = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ and $w(A_2) \leq 1/2$.
6. The vector norm $4w$ on $\mathbb{C}^{n\times n}$ is sub-multiplicative, i.e.,
$$4w(AB) \leq (4w(A))(4w(B)) \qquad \text{for all } A, B \in \mathbb{C}^{n\times n}.$$
   The equality holds if
$$A = B^T = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}.$$
7. Let $A \in \mathbb{C}^{n\times n}$ and k be a positive integer. Then
$$w(A^k) \leq w(A)^k.$$
   If A is invertible, then
$$w(A^{-k}) \geq w(A)^{-k},$$
   and the following conditions are equivalent.

   (a) A is a nonzero multiple of a unitary matrix.
   (b) $w(A^{-k}) = w(A)^{-k}$.
   (c) $w(A^{-1})^k = w(A^k)^{-1}$.

8. Let N be a unitary similarity invariant vector norm on $\mathbb{C}^{n\times n}$ such that $N(A^k) \leq N(A)^k$ for any $A \in \mathbb{C}^{n\times n}$ and positive integer k. Then

$$w(A) \leq N(A) \qquad \text{for all } A \in \mathbb{C}^{n\times n}.$$

9. Suppose N is a unitarily invariant vector norm on $\mathbb{C}^{n\times n}$. Let

$$D = \begin{cases} 2I_k \oplus 0_k & \text{if } n = 2k, \\ 2I_k \oplus I_1 \oplus 0_k & \text{if } n = 2k+1. \end{cases}$$

   Then $a = N(E_{11})$ and $b = N(D)$ are the best (largest and smallest) constants such that

$$aw(A) \leq N(A) \leq bw(A) \qquad \text{for all } A \in \mathbb{C}^{n\times n}.$$

10. Let $A \in \mathbb{C}^{n\times n}$. The following are equivalent.
   (a) $w(A) \leq 1$.
   (b) $\lambda_1(e^{it}A + e^{-it}A^*)/2 \leq 1$ for all $t \in [0, 2\pi)$.
   (c) There is $Z \in \mathbb{C}^{n\times n}$ such that $\begin{bmatrix} I_n + Z & A \\ A^* & I_n - Z \end{bmatrix}$ is positive semidefinite.
   (d) There exists $X \in \mathbb{C}^{2n\times n}$ satisfying $X^*X = I_n$ and

$$A = X^* \begin{bmatrix} 0_n & 2I_n \\ 0_n & 0_n \end{bmatrix} X.$$

   (d) There exists $B, C \in \mathbb{C}^{n\times n}$ such that $B^*B + C^*C = I_n$ and $A = 2B^*C$.

Examples:

1. For the matrix $A = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$ in Example 25.1.2, $w(A) = 1$.
2. Let $A = \begin{bmatrix} 1.5 & 2 \\ 0 & 0.5 \end{bmatrix}$ (see Example 25.1.3). As shown in Figure 25.1, $W(A)$ is an ellipse with foci 0.5 and 1.5 and minor axis of length 2. So $w(A) = \frac{2+\sqrt{5}}{2}$.
3. For the matrix $A = \operatorname{diag}(1, i, -1, -i) \oplus \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ in Example 25.1.3, $w(A) = 1$.

25.5 Products of Matrices

Facts:

The following facts can be found in [GR96, HJ91].

1. Let $A, B \in \mathbb{C}^{n\times n}$ be such that $\widetilde{w}(A) > 0$. Then

$$\sigma(A^{-1}B) \subseteq \{b/a : a \in W(A), b \in W(B)\}.$$

2. Let $0 \leq t_1 < t_2 < t_1 + \pi$, and $S = \{re^{it} : r > 0,\ t \in [t_1, t_2]\}$. Then $\sigma(A) \subseteq S$ if and only if there is a positive definite $B \in \mathbb{C}^{n\times n}$ such that $W(AB) \subseteq S$.

3. Let $A, B \in \mathbb{C}^{n\times n}$.
   (a) If $AB = BA$, then $w(AB) \le 2w(A)w(B)$.
   (b) If A or B is normal such that $AB = BA$, then $w(AB) \le w(A)w(B)$.
   (c) If $A^2 = aI$ and $AB = BA$, then $w(AB) \le \|A\|_2 w(B)$.
   (d) If $AB = BA$ and $AB^* = B^*A$, then $w(AB) \le \min\{w(A)\|B\|_2, \|A\|_2 w(B)\}$.
4. Let A and B be square matrices such that A or B is normal. Then
$$W(A \circ B) \subseteq W(A \otimes B) = \operatorname{conv}\{W(A)W(B)\}.$$
Consequently,
$$w(A \circ B) \le w(A \otimes B) = w(A)w(B).$$
(See Section 9.5 and Section 11.4 for the definitions of $A \circ B$ and $A \otimes B$.)
5. Let A and B be square matrices. Then
$$w(A \circ B) \le w(A \otimes B) \le \min\{w(A)\|B\|_2, \|A\|_2 w(B)\} \le 2w(A)w(B).$$
6. Let $A \in \mathbb{C}^{n\times n}$. Then
$$w(A \circ X) \le w(X) \quad \text{for all } X \in \mathbb{C}^{n\times n}$$
if and only if $A = B^*WB$ such that W satisfies $\|W\| \le 1$ and all diagonal entries of B^*B are bounded by 1.

Examples:

1. Let $A \in \mathbb{C}^{9\times 9}$ be the Jordan block of zero $J_9(0)$, and $B = A^3 + A^7$. Then $w(A) = w(B) = \cos(\pi/10) < 1$ and $w(AB) = 1 > \|A\|_2 w(B)$. So, even if $AB = BA$, we may not have $w(AB) \le \min\{w(A)\|B\|_2, \|A\|_2 w(B)\}$.
2. Let $A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$. Then $W(A) = \{a \in \mathbb{C} : |a-1| \le 1/2\}$ and
$$W(A^2) = \{a \in \mathbb{C} : |a-1| \le 1\}$$
where as
$$\operatorname{conv} W(A)^2 \subseteq \{se^{it} \in \mathbb{C} : s \in [0.25, 2.25],\ t \in [-\pi/3, \pi/3]\}.$$
So, $W(A^2) \not\subseteq \operatorname{conv} W(A)^2$.
3. Let $A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$ and $B = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$. Then $\sigma(AB) = \{i, -i\}$, $W(AB) = i[-1, 1]$ and $W(A) = W(B) = W(A)W(B) = [-1, 1]$. So, $\sigma(AB) \not\subseteq \operatorname{conv} W(A)W(B)$.

Applications:

1. If $C \in \mathbb{C}^{n\times n}$ is positive definite, then $W(C^{-1}) = W(C)^{-1} = \{c^{-1} : c \in W(C)\}$. Applying Fact 1 with $A = C^{-1}$
$$\sigma(CB) \subseteq W(C)W(B).$$
2. If $C \in \mathbb{C}^{n\times n}$ satisfies $\widetilde{w}(C) > 0$, then for every unit vector $\mathbf{x} \in \mathbb{C}^n$ $\mathbf{x}^*C^{-1}\mathbf{x} = \mathbf{y}^*C^*C^{-1}C\mathbf{y}$ with $\mathbf{y} = C^{-1}\mathbf{x}$, and hence
$$W(C^{-1}) \subseteq \{rb : r \ge 0, b \in W(C^*)\} = \{r\bar{b} : r \ge 0, b \in W(C)\}.$$
Applying this observation and Fact 1 with $A = C^{-1}$, we have
$$\sigma(AB) \subseteq \{rab : r \ge 0,\ a \in W(A),\ b \in W(B)\}.$$

25.6 Dilations and Norm Estimation

Definitions:

A matrix $A \in \mathbb{C}^{n\times n}$ has a **dilation** $B \in \mathbb{C}^{m\times m}$ if there is $X \in \mathbb{C}^{m\times n}$ such that $X^*X = I_n$ and $X^*BX = A$.

A matrix $A \in \mathbb{C}^{n\times n}$ is a **contraction** if $\|A\|_2 \leq 1$.

Facts:

The following facts can be found in [CL00, CL01] and their references.

1. A has a dilation B if and only if B is unitarily similar to a matrix of the form
$$\begin{bmatrix} A & * \\ * & * \end{bmatrix}.$$
2. Suppose $B \in \mathbb{C}^{2\times 2}$ or $B \in \mathbb{C}^{3\times 3}$ has a reducing eigenvector. If $W(A) \subseteq W(B)$, then A has a dilation of the form $B \otimes I_m$.
3. Let $r \in [-1, 1]$. Suppose $A \in \mathbb{C}^{n\times n}$ is a contraction with
$$W(A) \subseteq \mathcal{S} = \{a \in \mathbb{C} : a + \bar{a} \leq 2r\}.$$
Then A has a unitary dilation $U \in \mathbb{C}^{2n\times 2n}$ such that $W(U) \subseteq \mathcal{S}$.
4. Let $A \in \mathbb{C}^{n\times n}$. Then
$$W(A) = \cap\{W(B) : B \in \mathbb{C}^{2n\times 2n} \text{ is a normal dilation of } A\}.$$
If A is a contraction, then
$$W(A) = \cap\{W(U) : U \in \mathbb{C}^{2n\times 2n} \text{ is a unitary dilation of } A\}.$$
5. Let $A \in \mathbb{C}^{n\times n}$.
   (a) If $W(A)$ lies in a triangle with vertices z_1, z_2, z_3, then
$$\|A\|_2 \leq \max\{|z_1|, |z_2|, |z_3|\}.$$
   (b) If $W(A)$ lies in an ellipse $\mathcal{E}$ with foci λ_1, λ_2, and minor axis of length b, then
$$\|A\|_2 \leq \{\sqrt{(|\lambda_1| + |\lambda_2|)^2 + b^2} + \sqrt{(|\lambda_1| - |\lambda_2|)^2 + b^2}\}/2.$$
More generally, if $W(A)$ lies in the convex hull of the ellipse $\mathcal{E}$ and the point z_0, then
$$\|A\|_2 \leq \max\left\{|z_0|, \{\sqrt{(|\lambda_1| + |\lambda_2|)^2 + b^2} + \sqrt{(|\lambda_1| - |\lambda_2|)^2 + b^2}\}/2\right\}.$$
6. Let $A \in \mathbb{C}^{n\times n}$. Suppose there is $t \in [0, 2\pi)$ such that $e^{it}W(A)$ lies in a rectangle R centered at $z_0 \in \mathbb{C}$ with vertices $z_0 \pm \alpha \pm i\beta$ and $z_0 \pm \alpha \mp i\beta$, where $\alpha, \beta > 0$, so that $z_1 = z_0 + \alpha + i\beta$ has the largest magnitude. Then
$$\|A\|_2 \leq \begin{cases} |z_1| & \text{if } R \subseteq \text{conv}\{z_1, \bar{z}_1, -\bar{z}_1\}, \\ \alpha + \beta & \text{otherwise.} \end{cases}$$
The bound in each case is attainable.

Examples:

1. Let $A = \begin{bmatrix} 0 & \sqrt{2} \\ 0 & 0 \end{bmatrix}$. Suppose

$$B = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \quad \text{or} \quad B = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & i & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -i \end{bmatrix}.$$

Then $W(A) \subseteq W(B)$. However, A does not have a dilation of the form $B \otimes I_m$ for either of the matrices because

$$\|A\|_2 = \sqrt{2} > 1 = \|B\|_2 = \|B \otimes I_m\|_2.$$

So, there is no hope to further extend Fact 1 in this section to arbitrary $B \in \mathbb{C}^{3\times 3}$ or normal matrix $B \in \mathbb{C}^{4\times 4}$.

25.7 Mappings on Matrices

Definitions:

Let $\phi : \mathbb{C}^{n\times n} \to \mathbb{C}^{m\times m}$ be a linear map.

It is **unital** if $\phi(I_n) = I_m$.

It is **positive** if $\phi(A)$ is positive semidefinite whenever A is positive semidefinite.

Facts:

The following facts can be found in [GR96] unless another reference is given.

1. [HJ91] Let $\mathcal{P}(\mathbb{C})$ be the set of subsets of $\mathbb{C}$. Suppose a function $F : \mathbb{C}^{n\times n} \to \mathcal{P}(\mathbb{C})$ satisfies the following three conditions.
   (i) $F(A)$ is compact and convex for every $A \in \mathbb{C}^{n\times n}$.
   (ii) $F(aA + bI) = aF(A) + b$ for any $a, b \in \mathbb{C}$ and $A \in \mathbb{C}^{n\times n}$.
   (iii) $F(A) \subseteq \{a \in \mathbb{C} : a + \bar{a} \geq 0\}$ if and only if $A + A^*$ is positive semidefinite.

   Then $F(A) = W(A)$ for all $A \in \mathbb{C}^{n\times n}$.
2. Use the usual topology on $\mathbb{C}^{n\times n}$ and the Hausdorff metric on $\mathcal{K}(\mathbb{C})$ defined by

$$d(\mathcal{A}, \mathcal{B}) = \max\left\{ \max_{a\in\mathcal{A}} \min_{b\in\mathcal{B}} |a - b|, \max_{b\in\mathcal{B}} \min_{a\in\mathcal{A}} |a - b| \right\}$$

   for two compact sets $\mathcal{A}, \mathcal{B} \in \mathcal{K}(\mathbb{C})$. The mapping $A \mapsto W(A)$ is continuous.
3. Suppose $f(x+iy) = (ax+by+c)+i(dx+ey+f)$ for some real numbers a, b, c, d, e, f. Define $f(H+iG) = (aH+bG+cI)+i(dH+eG+fI)$ for any two Hermitian matrices $H, G \in \mathbb{C}^{n\times n}$. We have

$$W(f(H + iG)) = f(W(A)) = \{f(x + iy) : x + iy \in W(A)\}.$$

4. Let $\mathbf{D} = \{a \in \mathbb{C} : |a| \leq 1\}$. Suppose $f : \mathbf{D} \to \mathbb{C}$ is analytic in the interior of $\mathbf{D}$ and continuous on the boundary of $\mathbf{D}$.

   (a) If $f(\mathbf{D}) \subseteq \mathbf{D}$ and $f(0) = 0$, then $W(f(A)) \subseteq \mathbf{D}$ whenever $W(A) \subseteq \mathbf{D}$.

(b) If $f(\mathbf{D}) \subseteq \mathbb{C}_+ = \{a \in \mathbb{C} : a + \bar{a} \geq 0\}$, then $W(f(A)) \subseteq \mathbb{C}_+ \setminus \{(f(0) + \overline{f(0)})/2\}$ whenever $W(A) \subseteq \mathbf{D}$.

5. Suppose $\phi : \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ is a unital positive linear map. Then $W(\phi(A)) \subseteq W(A)$ for all $A \in \mathbb{C}^{n\times n}$.
6. [P75] Let $\phi : \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ be linear. Then

$$W(A) = W(\phi(A)) \quad \text{for all } A \in \mathbb{C}^{n\times n}$$

if and only if there is a unitary $U \in \mathbb{C}^{n\times n}$ such that ϕ has the form

$$X \mapsto U^*XU \qquad \text{or} \qquad X \mapsto U^*X^TU.$$

7. [Li87] Let $\phi : \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ be linear. Then $w(A) = w(\phi(A))$ for all $A \in \mathbb{C}^{n\times n}$ if and only if there exist a unitary $U \in \mathbb{C}^{n\times n}$ and a complex unit μ such that ϕ has the form

$$X \mapsto \mu U^*XU \qquad \text{or} \qquad X \mapsto \mu U^*X^TU.$$

Matrix Stability and Inertia

Daniel Hershkowitz
Bar-Ilan University and Technion - Israel Institute of Technology (Emeritus)

26.1 Inertia 26-2
26.2 Stability 26-3
26.3 Multiplicative D-Stability 26-5
26.4 Additive D-stability 26-7
26.5 Lyapunov Diagonal Stability 26-9
References 26-11

Much is known about spectral properties of square (complex) matrices. There are extensive studies of eigenvalues of matrices in certain classes. Some of the studies concentrate on the inertia of the matrices, that is, distribution of the eigenvalues in half-planes.

A special inertia case is of stable matrices, that is, matrices whose spectrum lies in the open left or right half-plane. These, and other related types of matrix stability, play an important role in various applications. For this reason, matrix stability has been intensively investigated in the past two centuries.

A. M. Lyapunov, called by F. R. Gantmacher "the founder of the modern theory of stability," studied the asymptotic stability of solutions of differential systems. In 1892, he proved a theorem that was restated (first, apparently, by Gantmacher in 1953) as a necessary and sufficient condition for stability of a matrix. In 1875, E. J. Routh introduced an algorithm that provides a criterion for stability. An independent solution was given by A. Hurwitz. This solution is known nowadays as the Routh–Hurwitz criterion for stability. Another criterion for stability, which has a computational advantage over the Routh–Hurwitz criterion, was proved in 1914 by Liénard and Chipart. The equivalent of the Routh–Hurwitz and Liénard–Chipart criteria was observed by M. Fujiwara. The related problem of requiring the eigenvalues to be within the unit circle was solved separately in the early 1900s by I. Schur and Cohn. The above-mentioned studies have motivated an intensive search for conditions for matrix stability.

An interesting question, related to stability, is the following one: Given a square matrix A, can we find a diagonal matrix D such that the matrix DA is stable? This question can be asked in full generality, as suggested above, or with some restrictions on the matrix D, such as positivity of the diagonal elements. A related problem is characterizing matrices A such that for every positive diagonal matrix D, the matrix DA is stable. Such matrices are called multiplicative D-stable matrices. This type of matrix stability, as well as two other related types, namely additive D-stability and Lyapunov diagonal (semi)stability, have important applications in many disciplines. Thus, they are very important to characterize. While regular stability is a spectral property (it is always possible to check whether a given matrix is stable by evaluating its eigenvalues), none of the other three types of matrix stability can be characterized by the spectrum of the matrix. This problem has been solved for certain classes of matrices. For example, for Z-matrices all the stability types are equivalent. Another case in which these characterization problems have been solved is the case of acyclic matrices.

Several surveys handle the above-mentioned types of matrix stability, e.g., the books [HJ91] and [KB00], and the articles [Her92], [Her98], and [BH85]. Finally, the mathematical literature has studies of other types of matrix stability, e.g., the above-mentioned Schur–Cohn stability (where all the eigenvalues lie within the unit circle), e.g., [Sch17] and [Zah92]; H-stability, e.g., [OS62], [Car68], and [HM98]; L_2-stability and strict H-stability, e.g., [Tad81]; and scalar stability, e.g., [HM98].

26.1 Inertia

Much is known about spectral properties of square matrices. In this chapter, we concentrate on the distribution of the eigenvalues in half-planes. In particular, we refer to results that involve the expression $AH+HA^*$, where A is a square complex matrix and H is a Hermitian matrix.

Definitions:

For a square complex matrix A, we denote by $\pi(A)$ the number of eigenvalues of A with positive real part, by $\delta(A)$ the number of eigenvalues of A on the imaginary axis, and by $\nu(A)$ the number of eigenvalues of A with negative real part. The **inertia** of A is defined as the triple $\text{in}(A) = (\pi(A), \nu(A), \delta(A))$.

Facts:

All the facts are proven in [OS62].

1. Let A be a complex square matrix. There exists a Hermitian matrix H such that the matrix $AH + HA^*$ is positive definite if and only if $\delta(A) = 0$. Furthermore, in such a case the inertias of A and H are the same.
2. Let $\{\lambda_1, \ldots, \lambda_n\}$ be the eigenvalues of an $n \times n$ matrix A. If $\prod_{i,j=1}^{n}(\lambda_i + \overline{\lambda_j}) \neq 0$, then for any positive definite matrix P there exists a unique Hermitian matrix H such that $AH + HA^* = P$. Furthermore, the inertias of A and H are the same.
3. Let A be a complex square matrix. We have $\delta(A) = \pi(A) = 0$ if and only if there exists an $n \times n$ positive definite Hermitian matrix such that the matrix $-(AH+HA^*)$ is positive definite.

Examples:

1. It follows from Fact 1 that a complex square matrix A has all of its eigenvalues in the right half-plane if and only if there exists a positive definite matrix H such that the matrix $AH + HA^*$ is positive definite. This fact, associating us with the discussion of the next section, is due to Lyapunov, originally proven in [Lya92] for systems of differential equations. The matrix formulation is due to [Gan60].
2. In order to demonstrate that both the existence and uniqueness claims of Fact 2 may be false without the condition on the eigenvalues, consider the matrix

$$A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix},$$

for which the condition of Fact 2 is not satisfied. One can check that the only positive definite matrices P for which the equation $AH + HA^* = P$ has Hermitian solutions are matrices of the type $P = \begin{bmatrix} p_{11} & 0 \\ 0 & p_{22} \end{bmatrix}$, $p_{11}, p_{22} > 0$. Furthermore, for $P = \begin{bmatrix} 2 & 0 \\ 0 & 4 \end{bmatrix}$ it is easy to verify that the Hermitian solutions of $AH + HA^* = P$ are all matrices H of the type

$$\begin{bmatrix} 1 & c \\ \bar{c} & -2 \end{bmatrix}, \quad c \in \mathbb{C}.$$

If we now choose

$$A = \begin{bmatrix} 1 & 0 \\ 0 & -2 \end{bmatrix},$$

then here the condition of Fact 2 is satisfied. Indeed, for $H = \begin{bmatrix} a & c \\ \bar{c} & b \end{bmatrix}$ we have

$$AH + HA^* = \begin{bmatrix} 2a & -c \\ -\bar{c} & -4b \end{bmatrix},$$

which can clearly be solved uniquely for any Hermitian matrix P; specifically, for $P = \begin{bmatrix} 2 & 0 \\ 0 & 4 \end{bmatrix}$, the unique Hermitian solution H of $AH + HA^* = P$ is $\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$.

26.2 Stability

Definitions:

A complex polynomial is **negative stable [positive stable]** if its roots lie in the open left [right] half-plane.

A complex square matrix A is **negative stable [positive stable]** if its characteristic polynomial is negative stable [positive stable].

We shall use the term **stable matrix** for positive stable matrix.

For an $n \times n$ matrix A and for an integer k, $1 \leq k \leq n$, we denote by $S_k(A)$ the sum of all principal minors of A of order k.

The **Routh–Hurwitz matrix** associated with A is defined to be the matrix

$$\begin{bmatrix}
S_1(A) & S_3(A) & S_5(A) & \cdot & \cdot & \cdot & \cdot & 0 & 0 \\
1 & S_2(A) & S_4(A) & & & & & \cdot & \cdot \\
0 & S_1(A) & S_3(A) & \cdot & & & & \cdot & \cdot \\
0 & 1 & S_2(A) & \cdot & \cdot & & & \cdot & \cdot \\
0 & 0 & S_1(A) & \cdot & \cdot & \cdot & & \cdot & \cdot \\
\cdot & \cdot & \cdot & & \cdot & \cdot & \cdot & 0 & 0 \\
\cdot & \cdot & \cdot & & & \cdot & \cdot & S_n(A) & 0 \\
\cdot & \cdot & \cdot & & & & \cdot & S_{n-1}(A) & 0 \\
0 & 0 & 0 & \cdot & \cdot & \cdot & \cdot & S_{n-2}(A) & S_n(A)
\end{bmatrix}.$$

A square complex matrix is a **P-matrix** if it has positive principal minors.

A square complex matrix is a **P_0^+-matrix** if it has nonnegative principal minors and at least one principal minor of each order is positive.

A principal minor of a square matrix is a **leading principal minor** if it is based on consecutive rows and columns, starting with the first row and column of the matrix.

An $n \times n$ real matrix A is **sign symmetric** if it satisfies

$$\det A[\alpha, \beta] \det A[\beta, \alpha] \geq 0, \qquad \forall \alpha, \beta \subseteq \{1, \ldots, n\}, \ |\alpha| = |\beta|.$$

An $n \times n$ real matrix A is **weakly sign symmetric** if it satisfies

$$\det A[\alpha, \beta] \det A[\beta, \alpha] \geq 0, \qquad \forall \alpha, \beta \subseteq \{1, \ldots, n\}, \ |\alpha| = |\beta| = |\alpha \cap \beta| + 1.$$

A square real matrix is a **Z-matrix** if it has nonpositive off-diagonal elements.

A Z-matrix with positive principal minors is an **M-matrix**. (See Section 10.5 for more information and an equivalent definition.)

Facts:

Lyapunov studied the asymptotic stability of solutions of differential systems. In 1892, he proved in his paper [Lya92] a theorem that yields a necessary and sufficient condition for stability of a complex matrix. The matrix formulation of Lyapunov's Theorem is apparently due to Gantmacher [Gan60], and is given as Fact 1 below. The theorem in [Gan60] was proven for real matrices; however, as was also remarked in [Gan60], the generalization to the complex case is immediate.

1. *The Lyapunov Stability Criterion:* A complex square matrix A is stable if and only if there exists a positive definite Hermitian matrix H such that the matrix $AH + HA^*$ is positive definite.
2. [OS62] A complex square matrix A is stable if and only if for every positive definite matrix G there exists a positive definite matrix H such that the matrix $AH + HA^* = G$.
3. [Rou77], [Hur95] *The Routh–Hurwitz Stability Criterion:* An $n \times n$ complex matrix A with a real characteristic polynomial is stable if and only if the leading principal minors of the Routh–Hurwitz matrix associated with A are all positive.
4. [LC14] (see also [Fuj26]) *The Liénard–Chipart Stability Criterion:* Let A be an $n \times n$ complex matrix with a real characteristic polynomial. The following are equivalent:
   (a) A is stable.
   (b) $S_n(A), S_{n-2}(A), \ldots > 0$ and the odd order leading principal minors of the Routh–Hurwitz matrix associated with A are positive.
   (c) $S_n(A), S_{n-2}(A), \ldots > 0$ and the even order leading principal minors of the Routh–Hurwitz matrix associated with A are positive.
   (d) $S_n(A), S_{n-1}(A), S_{n-3}(A), \ldots > 0$ and the odd order leading principal minors of the Routh–Hurwitz matrix associated with A are positive.
   (e) $S_n(A), S_{n-1}(A), S_{n-3}(A), \ldots > 0$ and the even order leading principal minors of the Routh–Hurwitz matrix associated with A are positive.
5. [Car74] Sign symmetric P-matrices are stable.
6. [HK03] Sign symmetric stable matrices are P-matrices.
7. [Hol99] Weakly sign symmetric P-matrices of order less than 6 are stable. Nevertheless, in general, weakly sign symetric P-matrices need not be stable.
8. (For example, [BVW78]) A Z-matrix is stable if and only if it is a P-matrix (that is, it is an M-matrix).
9. [FHR05] Let A be a stable real square matrix. Then either all the diagonal elements of A are positive or A has at least one positive diagonal element and one positive off-diagonal element.
10. [FHR05] Let ζ be an n-tuple of complex numbers, $n > 1$, consisting of real numbers and conjugate pairs. There exists a real stable $n \times n$ matrix A with exactly two positive entries such that ζ is the spectrum of A.

Examples:

1. Let

$$A = \begin{bmatrix} 2 & 2 & 3 \\ 2 & 5 & 4 \\ 3 & 4 & 5 \end{bmatrix}.$$

The Routh–Hurwitz matrix associated with A is

$$\begin{bmatrix} 12 & 1 & 0 \\ 1 & 16 & 0 \\ 0 & 12 & 1 \end{bmatrix}.$$

It is immediate to check that the latter matrix has positive leading principal minors. It, thus, follows that A is stable. Indeed, the eigenvalues of A are 1.4515, 0.0657, and 10.4828.

2. Stable matrices do not form a convex set, as is easily demonstrated by the stable matrices

$$\begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} 1 & 0 \\ 9 & 1 \end{bmatrix},$$

whose sum $\begin{bmatrix} 2 & 1 \\ 9 & 2 \end{bmatrix}$ has eigenvalues -1 and 5. Clearly, convex sets of stable matrices do exist. An example of such a set is the set of upper (or lower) triangular matrices with diagonal elements in the open right half-plane. Nevertheless, there is no obvious link between matrix stability and convexity or conic structure. Some interesting results on stable convex hulls can be found in [Bia85], [FB87], [FB88], [CL97], and [HS90]. See also the survey in [Her98].

3. In view of Facts 5 and 7, it would be natural to ask whether stability of a matrix implies that the matrix is a P-matrix or a weakly sign symmetric matrix. The answer to this question is negative as is demonstrated by the matrix

$$A = \begin{bmatrix} -1 & 1 \\ -5 & 3 \end{bmatrix}.$$

The eigenvalues of A are $1 \pm i$, and so A is stable. Nevertheless, A is neither a P-matrix nor a weakly sign symmetric matrix.

4. Sign symmetric P_0^+-matrices are not necessarily stable, as is demonstrated by the sign symmetric P_0^+-matrix

$$A = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 \end{bmatrix}.$$

The matrix A is not stable, having the eigenvalues $\left\{ e^{\pm \frac{2\pi i}{3}}, 1, 1, 1 \right\}$.

5. A P-matrix is not necessarily stable as is demonstrated by the matrix

$$\begin{bmatrix} 1 & 0 & 3 \\ 3 & 1 & 0 \\ 0 & 3 & 1 \end{bmatrix}.$$

For extensive study of spectra of P-matrices look at [HB83], [Her83], [HJ86], [HS93], and [HK03].

26.3 Multiplicative D-Stability

Multiplicative D-stability appears in various econometric models, for example, in the study of stability of multiple markets [Met45].

Definitions:

A real square matrix A is **multiplicative D-stable** if DA is stable for every positive diagonal matrix D.

In the literature, multiplicative D-stable matrices are usually referred to as just **D-stable** matrices.

A real square matrix A is **inertia preserving** if the inertia of AD is equal to the inertia of D for every nonsingular real diagonal matrix D.

The **graph** $G(A)$ of an $n \times n$ matrix A is the simple graph whose vertex set is $\{1, \ldots, n\}$, and where there is an edge between two vertices i and j $(i \neq j)$ if and only if $a_{ij} \neq 0$ or $a_{ji} \neq 0$. (See Chapter 39 more information on graphs.)

The matrix A is said to be **acyclic** if $G(A)$ is a forest.

Facts:

The problem of characterizing multiplicative D-stabity for certain classes and for matrices of order less than 5 is dealt with in several publications (e.g., [Cai76], [CDJ82], [Cro78], and [Joh74b]). However, in general, this problem is still open. Multiplicative D-stability is characterized in [BH84] for acyclic matrices. That result generalizes the handling of tridiagonal matrices in [CDJ82]. Characterization of multiplicative D-stability using cones is given in [HSh88]. See also the survey in [Her98].

1. Tridiagonal matrices are acyclic, since their graphs are paths or unions of disjoint paths.
2. [FF58] For a real square matrix A with positive leading principal minors, there exists a positive diagonal matrix D such that DA is stable.
3. [Her92] For a complex square matrix A with positive leading principal minors, there exists a positive diagonal matrix D such that DA is stable.
4. [Cro78] Multiplicative D-stable matrices are P_0^+-matrices.
5. [Cro78] A 2×2 real matrix is multiplicative D-stable if and only if it is a P_0^+-matrix.
6. [Cai76] A 3×3 real matrix A is multiplicative D-stable if and only if $A + D$ is multiplicative D-stable for every nonnegative diagonal matrix D.
7. [Joh75] A real square matrix A is multiplicative D-stable if and only if $A \pm iD$ is nonsingular for every positive diagonal matrix D.
8. (For example, [BVW78]) A Z-matrix is multiplicative D-stable if and only if it is a P-matrix (that is, it is an M-matrix).
9. [BS91] Inertia preserving matrices are multiplicative D-stable.
10. [BS91] An irreducible acyclic matrix is multiplicative D-stable if and only if it is inertia preserving.
11. [HK03] Let A be a sign symmetric square matrix. The following are equivalent:
    (a) The matrix A is stable.
    (b) The matrix A has positive leading principal minors.
    (c) The matrix A is a P-matrix.
    (d) The matrix A is multiplicative D-stable.
    (e) There exists a positive diagonal matrix D such that the matrix DA is stable.

Examples:

1. In order to illustrate Fact 2, let

$$A = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 4 & 1 & 2 \end{bmatrix}.$$

The matrix A is not stable, having the eigenvalues 4.0606 and $-0.0303 \pm 0.4953i$. Nevertheless, since A has positive leading minors, by Fact 2 there exists a positive diagonal matrix D such that the matrix DA is stable. Indeed, the eigenvalues of

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0.1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 4 & 1 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0.4 & 0.1 & 0.2 \end{bmatrix}$$

are 1.7071, 0.2929, and 0.2.

2. In order to illustrate Fact 4, let

$$A = \begin{bmatrix} 1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix}.$$

The matrix A is stable, having the eigenvalues $0.3376 \pm 0.5623i$ and 2.3247. Yet, we have $\det A[\{2,3\}] < 0$, and so A is not a P_0^+-matrix. Indeed, observe that the matrix

$$\begin{bmatrix} 0.1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix} = \begin{bmatrix} 0.1 & 0.1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix}$$

is not stable, having the eigenvalues $-0.1540 \pm 0.1335i$ and 2.408.

3. While stability is a spectral property, and so it is always possible to check whether a given matrix is stable or not by evaluating its eigenvalues, multiplicative D-stability cannot be characterized by the spectrum of the matrix, as is demonstrated by the following two matrices:

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}, \quad B = \begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix}.$$

The matrices A and B have the same spectrum. Nevertheless, while A is multiplicative D-stable, B is not, since it is not a P_0^+-matrix. Indeed, the matrix

$$\begin{bmatrix} 5 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix} = \begin{bmatrix} -5 & 10 \\ -3 & 4 \end{bmatrix}$$

has eigenvalues $-0.5 \pm 3.1225i$.

4. It is shown in [BS91] that the converse of Fact 9 is not true, using the following example from [Har80]:

$$A = \begin{bmatrix} 1 & 0 & -50 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix}.$$

The matrix A is multiplicative D-stable (by the characterization of 3×3 multiplicative D-stable matrices, proven in [Cai76]). However, for $D = \text{diag}\,(-1, 3, -1)$ the matrix AD is stable and, hence, A is not inertia preserving. In fact, it is shown in [BS91] that even P-matrices that are both D-stable and Lyapunov diagonally semistable (see Section 26.5) are not necessarily inertia preserving.

26.4 Additive *D*-stability

Applications of additive D-stability may be found in linearized biological systems, e.g., [Had76].

Definitions:

A real square matrix A is said to be **additive D-stable** if $A + D$ is stable for every nonnegative diagonal matrix D.

In some references, additive D-stable matrices are referred to as **strongly stable** matrices.

Facts:

The problem of characterizing additive D-stability for certain classes and for matrices of order less than 5 is dealt with in several publications (e.g., [Cai76], [CDJ82], [Cro78], and [Joh74b]). However, in general, this problem is still open. Additive D-stability is characterized in [Her86] for acyclic matrices. That result generalizes the handling of tridiagonal matrices in [Car84].

1. [Cro78] Additive D-stable matrices are P_0^+-matrices.
2. [Cro78] A 2×2 real matrix is additive D-stable if and only if it is a P_0^+-matrix.
3. [Cro78] A 3×3 real matrix A is additive D-stable if and only if it is a P_0^+-matrix and stable.
4. (For example, [BVW78]) A Z-matrix is additive D-stable if and only if it is a P-matrix (that is, it is an M-matrix).
5. An additive D-stable matrix need not be multiplicative D-stable (cf. Example 3).
6. [Tog80] A multiplicative D-stable matrix need not be additive D-stable.

Examples:

1. In order to illustrate Fact 1, let
$$A = \begin{bmatrix} 1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix}.$$
The matrix A is stable, having the eigenvalues $0.3376 \pm 0.5623i$ and 2.3247. Yet, we have $\det A[2,3|2,3] < 0$, and so A is not a P_0^+-matrix. Indeed, observe that the matrix
$$\begin{bmatrix} 1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix} + \begin{bmatrix} 2 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 3 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix}$$
is not stable, having the eigenvalues $2.5739 \pm 0.3690i$ and -0.1479.
2. While stability is a spectral property, and so it is always possible to check whether a given matrix is stable by evaluating its eigenvalues, additive D-stability cannot be characterized by the spectrum of the matrix, as is demonstrated by the following two matrices:
$$A = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}, \quad B = \begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix}.$$
The matrices A and B have the same spectrum. Nevertheless, while A is additive D-stable, B is not, since it is not a P_0^+-matrix. Indeed, the matrix
$$\begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 3 \end{bmatrix} = \begin{bmatrix} -1 & 2 \\ -3 & 7 \end{bmatrix}$$
has eigenvalues -0.1623 and 6.1623.
3. In order to demonstrate Fact 5, consider the matrix
$$A = \begin{bmatrix} 0.25 & 1 & 0 \\ -1 & 0.5 & 1 \\ 2.1 & 1 & 2 \end{bmatrix},$$

which is a P_0^+ matrix and is stable, having the eigenvalues $0.0205709 \pm 1.23009i$ and 2.70886. Thus, A is additively D-stable by Fact 3. Nevertheless, A is not multiplicative D-stable, as the eigenvalues of

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} 0.25 & 1 & 0 \\ -1 & 0.5 & 1 \\ 2.1 & 1 & 2 \end{bmatrix} = \begin{bmatrix} 0.25 & 1 & 0 \\ -5 & 2.5 & 5 \\ 8.4 & 4 & 8 \end{bmatrix}$$

are $-0.000126834 \pm 2.76183i$ and 10.7503.

26.5 Lyapunov Diagonal Stability

Lyapunov diagonally stable matrices play an important role in various applications, for example, predator–prey systems in ecology, e.g., [Goh76], [Goh77], and [RZ82]; dynamical systems, e.g., [Ara75]; and economic models, e.g., [Joh74a] and the references in [BBP78].

Definitions:

A real square matrix A is said to be **Lyapunov diagonally stable [semistable]** if there exists a positive diagonal matrix D such that $AD + DA^T$ is positive definite [semidefinite]. In this case, the matrix D is called a **Lyapunov scaling factor** of A.

In some references, Lyapunov diagonally stable matrices are referred to as just **diagonally stable** matrices or as **Volterra–Lyapunov stable**.

An $n \times n$ matrix A is said to be an **H-matrix** if the **comparison matrix** $M(A)$ defined by

$$M(A)_{ij} = \begin{cases} |a_{ii}|, & i = j \\ -|a_{ij}|, & i \neq j \end{cases}$$

is an M-matrix.

A real square matrix A is said to be **strongly inertia preserving** if the inertia of AD is equal to the inertia of D for every (not necessarily nonsingular) real diagonal matrix D.

Facts:

The problem of characterizing Lyapunov diagonal stability is, in general, an open problem. It is solved in [BH83] for acyclic matrices. Lyapunov diagonal semistability of acyclic matrices is characterized in [Her88]. Characterization of Lyapunov diagonal stability and semistability using cones is given in [HSh88]; see also the survey in [Her98]. For a book combining theoretical results, applications, and examples, look at [KB00].

1. [BBP78], [Ple77] Lyapunov diagonally stable matrices are P-matrices.
2. [Goh76] A 2×2 real matrix is Lyapunov diagonally stable if and only if it is a P-matrix.
3. [BVW78] A real square matrix A is Lyapunov diagonally stable if and only if for every nonzero real symmetric positive semidefinite matrix H, the matrix HA has at least one positive diagonal element.
4. [QR65] Lyapunov diagonally stable matrices are multiplicative D-stable.
5. [Cro78] Lyapunov diagonally stable matrices are additive D-stable.
6. [AK72], [Tar71] A Z-matrix is Lyapunov diagonally stable if and only if it is a P-matrix (that is, it is an M-matrix).
7. [HS85a] An H-matrix A is Lyapunov diagonally stable if and only if A is nonsingular and the diagonal elements of A are nonnegative.
8. [BS91] Lyapunov diagonally stable matrices are strongly inertia preserving.

9. [BH83] Acyclic matrices are Lyapunov diagonally stable if and only if they are P-matrices.
10. [BS91] Acyclic matrices are Lyapunov diagonally stable if and only if they are strongly inertia preserving.

Examples:

1. Multiplicative D-stable and additive D-stable matrices are not necessarily diagonally stable, as is demonstrated by the matrix
$$\begin{bmatrix} 1 & -1 \\ 1 & 0 \end{bmatrix}.$$
2. Another example, given in [BH85] is the matrix
$$\begin{bmatrix} 0 & 1 & 0 & 0 \\ -1 & 1 & 1 & 0 \\ 0 & 1 & a & b \\ 0 & 0 & -b & 0 \end{bmatrix}, \quad a \geq 1, b \neq 0,$$
which is not Lyapunov diagonally stable, but is multiplicative D-stable if and only if $a > 1$, and is additive D-stable whenever $a = 1$ and $b \neq 1$.
3. Stability is a spectral property, and so it is always possible to check whether a given matrix is stable by evaluating its eigenvalues; Lyapunov diagonal stability cannot be characterized by the spectrum of the matrix, as is demonstrated by the following two matrices:
$$A = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}, \quad B = \begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix}.$$
The matrices A and B have the same spectrum. Nevertheless, while A is Lyapunov diagonal stable, B is not, since it is not a P-matrix. Indeed, for every positive diagonal matrix D, the element of $AD + DA^T$ in the $(1, 1)$ position is negative and, hence, $AD + DA^T$ cannot be positive definite.
4. Let A be a Lyapunov diagonally stable matrix and let D be a Lyapunov scaling factor of A. Using continuity arguments, it follows that every positive diagonal matrix that is close enough to D is a Lyapunov scaling factor of A. Hence, a Lyapunov scaling factor of a Lyapunov diagonally stable matrix is not unique (up to a positive scalar multiplication). The Lyapunov scaling factor is not necessarily unique even in cases of Lyapunov diagonally semistable matrices, as is demonstrated by the zero matrix and the following more interesting example. Let
$$A = \begin{bmatrix} 2 & 2 & 3 \\ 2 & 2 & 3 \\ 1 & 1 & 2 \end{bmatrix}.$$
One can check that $D = \operatorname{diag}(1, 1, d)$ is a scaling factor of A whenever $\frac{1}{9} \leq d \leq 1$. On the other hand, it is shown in [HS85b] that the identity matrix is the unique Lyapunov scaling factor of the matrix
$$\begin{bmatrix} 1 & 1 & 2 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 2 & 1 & 2 \\ 2 & 2 & 0 & 1 \end{bmatrix}.$$
Further study of Lyapunov scaling factors can be found in [HS85b], [HS85c], [SB87], [HS88], [SH88], [SB88], and [CHS92].

27.1 Notation and Terminology 27-1
27.2 Moore-Penrose Inverse................................ 27-1
27.3 Drazin Inverse 27-7
27.4 Outer Inverse 27-13
27.5 Conjectures and Open Questions 27-17
Acknowledgments.. 27-17
References.. 27-18

Throughout this chapter, we will survey some basic results on the Moore-Penrose inverse, the Drazin inverse, and the outer inverse.

27.1 Notation and Terminology

Definitions:

Let F be a field (usually $\mathbb{C}$ or $\mathbb{R}$), let $A \in F^{m\times n}$, and let $\mathbf{b} \in F^m$.

For integers $m \geq 1$ and $1 \leq k \leq m$,

$$Q_{k,m} = \{\alpha : \alpha = (\alpha_1, \alpha_2, \dots, \alpha_k), 1 \leq \alpha_1 < \alpha_2 < \cdots < \alpha_k \leq m, \text{ and } \alpha_1, \alpha_2, \dots, \alpha_k \text{ are integers}\}.$$

For $\alpha \in Q_{k,m}$ and $\beta \in Q_{l,n}$, the **submatrix** $A[\alpha, \beta]$ is the $k \times l$ matrix whose (i, j)-th element is the (α_i, β_j) element of A; see Chapter 11 for additional information about submatrices. If $|\beta| = n$ (or $|\alpha| = m$), then the notation $A[\alpha, *]$ (or $A[*, \beta] = A[\alpha, \beta]$) is used to denote $A[\alpha, \beta]$.

For $\alpha \in Q_{k,m}$, $\mathbf{b}[\alpha]$ is the subvector of $\mathbf{b}$, whose i-th element is the α_i element of $\mathbf{b}$.

$\mathcal{I}(A) = \{\alpha \in Q_{r,m} : \operatorname{rank}(A[\alpha, *]) = r\}$, $\mathcal{J}(A) = \{\beta \in Q_{r,n} : \operatorname{rank}(A[*, \beta]) = r\}$, and $\mathcal{N}(A) = \{(\alpha, \beta) \in Q_{r,m} \times Q_{r,n} : \operatorname{rank}(A[\alpha, \beta]) = r\}$.

The **embedding** of $A[\alpha, \beta]$, denoted by $\widehat{A[\alpha, \beta]}$ is the $m \times n$ matrix with $\widehat{A[\alpha, \beta]}[\alpha, \beta] = A[\alpha, \beta]$ and zeros elsewhere.

The **embedding** of $\mathbf{b}[\alpha]$, denoted by $\widehat{\mathbf{b}[\alpha]}$ is an $m \times 1$ vector with $\widehat{\mathbf{b}[\alpha]}[\alpha] = \mathbf{b}[\alpha]$ and zeros elsewhere.

$\mathbb{C}_r^{m\times n}$ denotes the set of complex $m \times n$ matrices with rank r.

27.2 Moore-Penrose Inverse

Definitions:

Let $A \in \mathbb{C}^{m\times n}$.

The matrix $X \in \mathbb{C}^{n\times m}$ satisfying four matrix equations:

$$AXA = A, \quad XAX = X, \quad (AX)^* = AX, \quad (XA)^* = XA,$$

is called the **Moore-Penrose inverse** of A [Moo20, Pen55], and denoted by $X = A^\dagger$.

Let $P_{\text{range}(A)} = AA^\dagger$ and $P_{\text{range}(A^*)} = A^\dagger A$. A matrix $B = A + E \in \mathbb{C}^{m\times n}$ is said to be an **acute perturbation** [Ste77, Wed73] of A, if

$$\left\|P_{\text{range}(B)} - P_{\text{range}(A)}\right\| < 1, \quad \text{and} \quad \left\|P_{\text{range}(B^*)} - P_{\text{range}(A^*)}\right\| < 1.$$

Let $B = A + E \in \mathbb{C}^{m\times n}$ be a perturbation of A. Then B is said to be a **stable perturbation** [CWX96] of A if

$$\text{range}(B) \cap \text{range}^\perp(A) = \{0\}.$$

Let $M \in \mathbb{C}^{k_1\times m}, K \in \mathbb{C}^{k_2\times n}$. Then the matrix $X \in \mathbb{C}^{n\times m}$ satisfying the following equations:

$$MAXA = MA, \quad XAX = X, \quad (M^*MAX)^* = M^*MAX, \quad (K^*KXA)^* = K^*KXA,$$

is called the **weighted Moore-Penrose inverse** of A, and denoted by $X = A^\dagger_{M,K}$ [Eld82].

Facts:

Notation: Unless otherwise specified, $A \in \mathbb{C}^{m\times n}$.

1. The Moore-Penrose inverse $A^\dagger$ of A is unique.
2. [BG03, Chap. 6] Let A have a singular value decomposition (SVD) $A = U \begin{bmatrix} \Sigma & 0 \\ 0 & 0 \end{bmatrix} V^* \in \mathbb{C}_r^{m\times n}$, where $U \in \mathbb{C}^{m\times m}$ and $V \in \mathbb{C}^{n\times n}$ are unitary, the singular values $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_r > 0$ and $\Sigma = \text{diag}(\sigma_1, \sigma_2, \cdots, \sigma_r) \in \mathbb{R}^{r\times r}$. Then the Moore-Penrose inverse $A^\dagger$ is given by
$$A^\dagger = V \begin{bmatrix} \Sigma^{-1} & 0 \\ 0 & 0 \end{bmatrix} U^* \in \mathbb{C}_r^{n\times m}.$$
Furthermore,
$$P_{\text{range}(A)} = AA^\dagger = U \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} U^* \in \mathbb{C}_r^{m\times m}$$
and
$$P_{\text{range}(A^*)} = A^\dagger A = V \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} V^* \in \mathbb{C}_r^{n\times n}$$
are orthogonal projectors onto range(A) and range(A^*), respectively. $\|A\|_2 = \sigma_1$ and $\left\|A^\dagger\right\|_2 = 1/\sigma_r$ ($\|\cdot\|_2$ is the spectral norm; see Chapter 50). If $m = n$ and A is invertible, then $A^\dagger = A^{-1}$.
3. $A = 0$ if and only if $A^\dagger = 0$.
4. $(A^\dagger)^\dagger = A$ and $(A^\dagger)^* = (A^*)^\dagger$.
5. $\text{range}(A^\dagger) = \text{range}(A^*) = \text{range}(A^*A) = \text{range}(A^\dagger A) = \ker(I - A^\dagger A)$.
6. $\ker(A^\dagger) = \ker(A^*) = \ker(AA^*) = \ker(AA^\dagger) = \text{range}(I - AA^\dagger)$.
7. $\mathbb{C}^m = \text{range}(A) \oplus \ker(A^\dagger)$ and $\mathbb{C}^n = \text{range}(A^\dagger) \oplus \ker(A)$.
8. [Gro77, Chap. 2] If A is of full column rank, then $A^\dagger = \int_0^\infty e^{-A^*At}A^*dt = (A^*A)^{-1}A^*$. If A is of full row rank, then $A^\dagger = \int_0^\infty A^*e^{-AA^*t}dt = A^*(AA^*)^{-1}$.
9. [Gro77, Chap. 2] $A^\dagger = \widetilde{A}^{-1}A^*$, where $\widetilde{A} = (A^*A)|_{\text{range}(A^*)}$ is the restriction of A^*A to range(A^*).
10. [CM79, Chap. 1] $A^\dagger = \frac{1}{2\pi i}\int_\Gamma \frac{1}{z}(zI - A^*A)^{-1}A^*dz$ ($i = \sqrt{-1}$), where Γ is a closed contour containing the non-zero eigenvalues of A^*A, but not containing the zero eigenvalues of A^*A in or on it.

11. [BG03, Chap. 3] $A^\dagger = \lim_{\varepsilon\to 0}(A^*A+\varepsilon I)^{-1}A^* = \lim_{\varepsilon\to 0} A^*(AA^*+\varepsilon I)^{-1}$.
12. [GV13, Chap. 5] $\left\|A^\dagger - (A^*A+\varepsilon I)^{-1}A^*\right\|_2 = \frac{\varepsilon}{\sigma_r(A)[\sigma_r^2(A)+\varepsilon]}$, for $\varepsilon > 0$ and $r = \operatorname{rank}(A)$, $\sigma_r(A)$ is the smallest singular value of A.
13. [BG03, Chap. 2] For $A \in \mathbb{C}^{m\times n}$ and $B \in \mathbb{C}^{k\times \ell}$, $(A\otimes B)^\dagger = A^\dagger \otimes B^\dagger$, where $\otimes$ is a Kronecker product (see Chapter 11).
14. [BG03, Chap. 6] $(UAV)^\dagger = V^*A^\dagger U^*$, where U and V are unitary matrices.
15. Let $A \in \mathbb{C}_r^{m\times r}, B \in \mathbb{C}_r^{r\times n}$. Then $(AB)^\dagger = B^\dagger A^\dagger = B^*(BB^*)^{-1}(A^*A)^{-1}A^*$.
16. [BP79, Chap. 7] Let $A = M - N \in \mathbb{C}^{m\times n}$ be a splitting of A such that range$(A) =$ range(M) and ker$(A) =$ ker(M) (this is called a *proper splitting*). Then
$$A^\dagger = \left(I_n - M^\dagger N\right)^{-1} M^\dagger = M^\dagger\left(I_m - NM^\dagger\right)^{-1}.$$
17. [CF79] Let $A, B \in \mathbb{C}^{m\times n}$. Assume that $A^*B = 0$, then
$$(A+B)^\dagger = A^\dagger + \left(I_n - A^\dagger B\right)\left(C^\dagger + D\right),$$
where $D = (I_n - C^\dagger C)[I_n + (I_n - C^\dagger C)B^*(AA^*)^\dagger B(I_n - C^\dagger C)]^{-1}B^*(AA^*)^\dagger(I_m - BC^\dagger)$ and $C = (I_m - AA^\dagger)B$. Furthermore, suppose that $A^*B = 0$ and $AB^* = 0$. Then $(A+B)^\dagger = A^\dagger + B^\dagger$ and rank$(A+B) =$ rank$(A) +$ rank(B).
18. [CF79] Let $A, B \in \mathbb{C}^{m\times n}$. Then $(A+B)^\dagger = (I_n + A^\dagger B)^\dagger (A^\dagger + A^\dagger B A^\dagger)(I_m + BA^\dagger)^\dagger$ if and only if $AA^\dagger B = BA^\dagger A = B$. Furthermore, if rank$(A+B) =$ rank(A), then
$$(A+B)^\dagger = \left(I_n + A^\dagger B\right)^{-1} A^\dagger = A^\dagger\left(I_m + BA^\dagger\right)^{-1}.$$
19. [Ste77, Wed73] Let $\{A_j\}_0^\infty$ be a sequence of matrices in $\mathbb{C}^{m\times n}$. If A_j converges to A, then $A_j^\dagger$ converges to $A^\dagger$ if and only if there exists a j_0 such that rank$(A_j) =$ rank(A) for $j \geq j_0$.
20. $\begin{bmatrix} A & 0 \\ 0 & B\end{bmatrix}^\dagger = \begin{bmatrix} A^\dagger & 0 \\ 0 & B^\dagger\end{bmatrix}$, $\begin{bmatrix} 0 & A \\ B & 0\end{bmatrix}^\dagger = \begin{bmatrix} 0 & B^\dagger \\ A^\dagger & 0\end{bmatrix}$, $[A \;\; 0]^\dagger = \begin{bmatrix} A^\dagger \\ 0\end{bmatrix}$.
21. [SS02] Let $M = \begin{bmatrix} B & 0 \\ C & D\end{bmatrix}$, where B has full column rank and D is of full row rank. Then $M^\dagger = \begin{bmatrix} B^\dagger & 0 \\ -D^\dagger C B^\dagger & D^\dagger\end{bmatrix}$.
22. [Dym07, p. 237] Let $A \in \mathbb{C}^{n\times n}, B \in \mathbb{C}^{n\times m}$, and assume that $BB^* = I_n$. Then
$$\begin{bmatrix} A & B \\ B^* & 0\end{bmatrix}^\dagger = \begin{bmatrix} 0 & B \\ B^* & -B^*AB\end{bmatrix}.$$
23. [CM79, Chap. 1] Let $A \in \mathbb{C}^{m\times n}$ and $B \in \mathbb{C}^{n\times p}$. Then the following statements are equivalent:
    (i) $(AB)^\dagger = B^\dagger A^\dagger$.
    (ii) $(AB)(AB)^\dagger = (AB)B^\dagger A^\dagger$ and $(AB)^\dagger AB = B^\dagger A^\dagger AB$.
    (iii) $A^*AB = BB^\dagger A^*AB$ and $ABB^* = ABB^*A^\dagger A$.
    (iv) $AB(AB)^\dagger A = ABB^\dagger$ and $A^\dagger AB = B(AB)^\dagger AB$.
    (v) $A^*ABB^\dagger = BB^\dagger A^*A$ and $A^\dagger ABB^* = BB^*A^\dagger A$.
    (vi) $(ABB^\dagger)^\dagger = BB^\dagger A^\dagger$ and $(A^\dagger AB)^\dagger = B^\dagger A^\dagger A$.
    (vii) $B^\dagger(ABB^\dagger)^\dagger = B^\dagger A^\dagger$ and $(A^\dagger AB)^\dagger A = B^\dagger A^\dagger$.
    (viii) range$(A^*AB) \subseteq$ range(B) and range$(BB^*A^*) \subseteq$ range(A^*).
24. [DW07] Let $A \in \mathbb{C}_n^{m\times n}$. Then
$$\lim_{\epsilon\to 0}\sup_{\|E\|_F\leq\epsilon}\frac{\left\|(A+E)^\dagger - A^\dagger\right\|_F}{\|E\|_F}\frac{\|A\|_F}{\left\|A^\dagger\right\|_F} = \frac{\left\|A^\dagger\right\|_2^2\|A\|_F}{\left\|A^\dagger\right\|_F}.$$

25. [BG03, Chap. 7] Let $A \in \mathbb{C}^{m\times n}$. Define the sequence $\{X_i\}_0^\infty$ by

$$X_{i+1} = 2X_i - X_i A X_i,$$

where $X_0 = \varepsilon A^*$ and $0 < \varepsilon \le 2/\|A\|_2^2$. Then $\lim\limits_{i\to\infty} X_i = A^\dagger$.

26. [Dec65] Let $A \in \mathbb{C}_r^{m\times n}$. The characteristic polynomial of A^*A is

$$\det(\lambda I_n - A^*A) = \lambda^n + c_1\lambda^{n-1} + \cdots + c_{n-1}\lambda + c_n,$$

such that $c_{r+1} = c_{r+2} = \cdots = c_n = 0$. Then

$$A^\dagger = -\left[(A^*A)^{r-1} + c_1(A^*A)^{r-2} + \cdots + c_{r-1}I_n\right] A^*/c_r.$$

27. [FM93] Let $A \in \mathbb{C}^{m\times n}$. Then $X = A^\dagger$ is the unique matrix satisfying

$$\operatorname{rank}\left(\begin{bmatrix} A & AA^\dagger \\ A^\dagger A & X \end{bmatrix}\right) = \operatorname{rank}(A).$$

28. [Ste77, Wed73] The following statements are equivalent:
(i) $\left\|P_{\text{range}(B)} - P_{\text{range}(A)}\right\| < 1$.
(ii) $\text{range}(B) \cap \text{range}^\perp(A) = \{0\}$, and $\text{range}(A) \cap \text{range}^\perp(B) = \{0\}$.
(iii) $\text{rank}(B) = \text{rank}(A) = \text{rank}(P_{\text{range}(A)}B)$.

29. [Ste77, Wed73] If $B = A + E \in \mathbb{C}^{m\times n}$ is not an acute perturbation, then

$$\left\|B^\dagger - A^\dagger\right\|_2 \ge \frac{1}{\|E\|_2}, \qquad \left\|B^\dagger\right\|_2 \ge \frac{1}{\|E\|_2}.$$

30. [Ste77, Wed73] Let $B = A + E \in \mathbb{C}^{m\times n}$. Then

$$\left\|B^\dagger - A^\dagger\right\| \le \mu \max\left\{\left\|A^\dagger\right\|_2^2, \left\|B^\dagger\right\|_2^2\right\} \|E\|,$$

where μ is listed in the following table:

$\|\cdot\|$	Unitary Invariant Norm	2-Norm	Frobenius-Norm
μ	3	$\frac{1+\sqrt{5}}{2}$	$\sqrt{2}$

In particular, if $\text{rank}(A) = \text{rank}(B)$, then

$$\left\|B^\dagger - A^\dagger\right\| \le \mu \left\|A^\dagger\right\|_2 \left\|B^\dagger\right\|_2 \|E\|, \qquad \left\|B^\dagger\right\|_2 \le \frac{\left\|A^\dagger\right\|_2}{1 - \left\|A^\dagger\right\|_2 \|E\|_2},$$

where μ is listed in the following table:

rank $\backslash$ $\|\cdot\|$	Unitary Invariant Norm	2-Norm	Frobenius-Norm
$\text{rank}(A) < n \le m$	3	$\frac{1+\sqrt{5}}{2}$	$\sqrt{2}$
$\text{rank}(A) = n < m$	2	$\sqrt{2}$	1
$\text{rank}(A) = n = m$	1	1	1

31. [CX98, LXW13] Let $B = A + E \in \mathbb{C}^{m\times n}$ be a perturbation of A. If $\left\|A^\dagger\right\| \; \|E\| < 1$, then the following statements are equivalent:
(i) B is a stable perturbation of A.
(ii) B is an acute perturbation of A.
(iii) $\text{rank}(B) = \text{rank}(A)$.

32. [XWG10, LXW13] For $A \in \mathbb{C}^{m\times n}$. Let $B = A + E$ be a stable perturbation of A satisfying the condition $\|A^\dagger\|_2 \|E\|_2 < 1$. Then

$$\|B^\dagger\|_2 \le \varepsilon \frac{\|A^\dagger\|_2}{1 - \|A^\dagger\|_2 \|E\|_2}, \qquad \frac{\|B^\dagger - A^\dagger\|_2}{\|A^\dagger\|_2} \le \varepsilon \frac{\|A^\dagger\|_2 \|E\|_2}{1 - \|A^\dagger\|_2 \|E\|_2},$$

$\varepsilon < 1$ if and only if $\text{range}(B) \cap \text{range}(A) = \{0\}$ and $\text{range}(B^*) \cap \text{range}(A^*) = \{0\}$.

33. [MZ10, CXL11] Let $B = A + E \in \mathbb{C}^{m\times n}$. Then

$$\|B^\dagger - A^\dagger\|_F \le \max\left\{\|A^\dagger\|_2^2, \|B^\dagger\|_2^2\right\} \|E\|_F.$$

If $\text{rank}(B) = \text{rank}(A) = r$, then $\|B^\dagger - A^\dagger\|_F \le \|A^\dagger\|_2 \|B^\dagger\|_2 \|E\|_F$.

34. [WW00b] Let $B = A + E \in \mathbb{C}^{m\times n}$ with $\text{rank}(B) = \text{rank}(A) = r$. Assume that $I_n + A^\dagger E$ is nonsingular. Then

$$\begin{aligned} B^\dagger &= \left(A^\dagger A + X^*\right)\left[A^\dagger A - X(I_n + X^*X)^{-1}X^*\right]\left(I_n + A^\dagger E\right)^{-1} A^\dagger \\ &\quad \times \left[AA^\dagger - Y^*(I_m + YY^*)^{-1}Y\right]\left(AA^\dagger + Y^*\right), \end{aligned}$$

where $X = (I_n + A^\dagger E)^{-1}A^\dagger E(I_n - A^\dagger A)$ and $Y = (I_m - AA^\dagger)EA^\dagger(I_m + EA^\dagger)^{-1}$.

35. Let $B = A + E \in \mathbb{C}^{m\times n}$. Assume that $I_n + A^\dagger E$ is nonsingular.
(a) [WW00b] If $AA^\dagger E = E$, then $\ker(B^\dagger) = \ker(A^\dagger)$, and

$$B^\dagger = \left(A^\dagger A + X^*\right)\left[A^\dagger A - X(I_n + X^*X)^{-1}X^*\right]\left(I_n + A^\dagger E\right)^{-1} A^\dagger,$$

where $X = (I_n + A^\dagger E)^{-1}A^\dagger E(I_n - A^\dagger A)$.
(b) [WW00b] If $EA^\dagger A = E$, then $\text{range}(B^\dagger) = \text{range}(A^\dagger)$, and

$$B^\dagger = \left(I_n + A^\dagger E\right)^{-1} A^\dagger \left[AA^\dagger - Y^*(I_m + YY^*)^{-1}Y\right]\left(AA^\dagger + Y^*\right),$$

where $Y = (I_m - AA^\dagger)EA^\dagger(I_m + EA^\dagger)^{-1}$.
(c) [BG03, Chap. 6] If $AA^\dagger E = EA^\dagger A = E$, then $\text{range}(B^\dagger) = \text{range}(A^\dagger)$, $\ker(B^\dagger) = \ker(A^\dagger)$ and,

$$B^\dagger = \left(I_n + A^\dagger E\right)^{-1} A^\dagger = A^\dagger\left(I_m + EA^\dagger\right)^{-1}, \quad BB^\dagger = AA^\dagger, \quad B^\dagger B = A^\dagger A.$$

36. [BG03, Chap. 5] Let $A \in \mathbb{C}_r^{m\times n}$, $U \in \mathbb{C}_{m-r}^{m\times(m-r)}$ and $V^* \in \mathbb{C}_{n-r}^{n\times(n-r)}$ be matrices whose columns form bases for $\ker(A^*)$ and $\ker(A)$, respectively. Then $\mathcal{A} = \begin{bmatrix} A & U \\ V & 0 \end{bmatrix}$ is nonsingular and $\mathcal{A}^{-1} = \begin{bmatrix} A^\dagger & V^\dagger \\ U^\dagger & 0 \end{bmatrix}$.

37. [Ber86] The Moore-Penrose inverse of $A \in \mathbb{R}_r^{m\times n}$ is a convex combination of ordinary inverses of $r \times r$ submatrices

$$A^\dagger = \sum_{(I,J)\in\mathcal{N}(A)} \lambda_{IJ} \widehat{A_{IJ}^{-1}},$$

where each $\widehat{A_{IJ}^{-1}}$ is an $n \times m$ matrix with the inverse of A_{IJ} in position (J, I) and zeros elsewhere, and

$$\lambda_{IJ} = \frac{\det^2(A_{IJ})}{\sum\limits_{(I,J)\in\mathcal{N}(A)} \det^2(A_{IJ})}.$$

38. [Bjo96, Chap. 1][BG03, Chap. 3] For $A \in \mathbb{C}^{m\times n}$, any solution of the linear least squares problem (LS)
$$\min_{\mathbf{x}} \|A\mathbf{x} - \mathbf{b}\|_2$$
is given by $\mathbf{x} = A^\dagger \mathbf{b} + (I_n - A^\dagger A)\mathbf{y}$, for arbitrary $\mathbf{y}$. The LS solution is unique if and only if A is of full column rank. The minimum-norm least squares solution $A^\dagger \mathbf{b}$ is
$$A^\dagger \mathbf{b} = \sum_{(I,J)\in\mathcal{N}(A)} \lambda_{IJ} \widehat{A_{IJ}^{-1}\mathbf{b}_I},$$
where $\mathbf{b}_I$ is the I-th subvector of $\mathbf{b}$.
39. [Eld82] The weighted Moore-Penrose inverse $A^\dagger_{M,K}$ can be expressed by $A^\dagger_{M,K} = \left[I_n - (KP_0)^\dagger K\right](MA)^\dagger M$, where $P_0 = I_n - (MA)^\dagger MA$.
40. [Eld82, WZ94] The weighted Moore-Penrose inverse $A^\dagger_{M,K}$ is unique if and only if
$$A = 0, \quad \text{or} \quad \operatorname{rank}\left(\begin{bmatrix} MA \\ K \end{bmatrix}\right) \text{ is of full column rank.}$$
41. [Eld82, WZ94, Wei01] Consider the linear least squares problems with linear equality constraints (LSE) with $A \in \mathbb{C}^{s\times n}, M \in \mathbb{C}^{m_1\times s}$, and $K \in \mathbb{C}^{m_2\times n}$,
$$\min \|\mathbf{f}\|_K \quad \text{with} \quad S = \left\{\mathbf{f} : \|A\mathbf{f} - \mathbf{g}\|_M = \min_{\mathbf{z}\in\mathbb{C}^n} \|A\mathbf{z} - \mathbf{g}\|_M\right\},$$
where $\|\cdot\|_K$ and $\|\cdot\|_M$ are the ellipsoidal semi-norms:
$$\|\mathbf{f}\|_K^2 = \mathbf{f}^* K^* K \mathbf{f}, \quad \|\mathbf{g}\|_M^2 = \mathbf{g}^* M^* M \mathbf{g}.$$
Then the solution $A^\dagger_{M,K}\mathbf{g}$ of LSE problem is unique if and only if $\operatorname{rank}\left(\begin{bmatrix} MA \\ K \end{bmatrix}\right) = n$.

Examples:

1. For $A = \begin{bmatrix} 4 & 0 \\ 0 & 0 \end{bmatrix}$, $A^\dagger = \begin{bmatrix} \frac{1}{4} & 0 \\ 0 & 0 \end{bmatrix}$ can be verified from the definition of the Moore-Penrose inverse.
2. [CM79, Example 1.3.4] Let $A = \begin{bmatrix} 1 & 2 & 1 & 4 & 1 \\ 2 & 4 & 0 & 6 & 6 \\ 1 & 2 & 0 & 3 & 3 \\ 2 & 4 & 0 & 6 & 6 \end{bmatrix}$. We can compute $A^\dagger$ by using Fact 15. We get the full-rank factorization of $A = BC$,
$$B = \begin{bmatrix} 1 & 1 \\ 2 & 0 \\ 1 & 0 \\ 2 & 0 \end{bmatrix}, \qquad C = \begin{bmatrix} 1 & 2 & 0 & 3 & 3 \\ 0 & 0 & 1 & 1 & -2 \end{bmatrix}.$$
Calculating
$$\left(CC^T\right)^{-1} = \frac{1}{129} = \begin{bmatrix} 6 & 3 \\ 3 & 23 \end{bmatrix}, \qquad \left(B^T B\right)^{-1} = \frac{1}{9}\begin{bmatrix} 1 & -1 \\ -1 & 10 \end{bmatrix}.$$
Thus,
$$A^\dagger = C^T \left(CC^T\right)^{-1} \left(B^T B\right)^{-1} B^T = \frac{1}{1161} \begin{bmatrix} 27 & 6 & 3 & 6 \\ 54 & 12 & 6 & 12 \\ 207 & -40 & -20 & -40 \\ 288 & -22 & -11 & -22 \\ -333 & 98 & 49 & 98 \end{bmatrix}.$$

3. [Dat10, Example 10.12] Let $A = \begin{bmatrix} 0 & 0 & -1 \\ -1 & 0 & 0 \\ 0 & -1 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \frac{1}{3} & -\frac{6}{9} & -\frac{6}{9} \\ -\frac{6}{9} & \frac{1}{3} & -\frac{6}{9} \\ -\frac{6}{9} & -\frac{6}{9} & \frac{1}{3} \end{bmatrix} = U\Sigma V^T$.

   We can compute $A^\dagger$ by using the SVD:

$$A^\dagger = V\Sigma^\dagger U^T = \begin{bmatrix} \frac{1}{3} & -\frac{6}{9} & -\frac{6}{9} \\ -\frac{6}{9} & \frac{1}{3} & -\frac{6}{9} \\ -\frac{6}{9} & -\frac{6}{9} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 & -1 & 0 \\ 0 & 0 & -1 \\ -1 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 0 & -\frac{1}{3} & \frac{1}{3} \\ 0 & \frac{2}{3} & -\frac{1}{6} \\ 0 & \frac{2}{3} & \frac{1}{3} \end{bmatrix}.$$

27.3 Drazin Inverse

Definitions:

Let $A \in \mathbb{C}^{n\times n}$.

The **index** of A, denoted index(A), is the smallest nonnegative integer k that satisfies

$$\text{rank}\left(A^k\right) = \text{rank}\left(A^{k+1}\right).$$

The definition of index is the same as the index of eigenvalue 0, $\nu_A(0)$ (see Chapter 6).

Let index$(A) = k$. Then a matrix $X \in \mathbb{C}^{n\times n}$ satisfying

$$A^{k+1}X = A^k, \quad XAX = X, \quad AX = XA,$$

is called the **Drazin inverse** of A [Dra58], and denoted by A^D.

If a matrix $X \in \mathbb{C}^{n\times n}$ satisfies

$$AXA = A, \quad XAX = X, \quad AX = XA,$$

then X is called the **group inverse** of A and denoted by A_g (in the literature the group inverse is sometimes denoted $A^\#$).

A matrix A that has a group inverse is **group invertible**.

A matrix H is called **semi-convergent** [BP79, Chap. 7], if and only if
(i) the spectral radius $\rho(H) \le 1$.
(ii) If $\rho(H) = 1$, then all the Jordan blocks associating with 1 for H are one-by-one.
(iii) If $\rho(H) = 1$, then $\lambda \in \sigma(H)$ and $|\lambda| = 1$ implies $\lambda = 1$.

A matrix $B = A + E \in \mathbb{C}^{n\times n}$ is said to be a **stable perturbation** of A [XSW10, XWS12], if

$$I - A^\pi - B^\pi \quad \text{is nonsingular,}$$

where $A^\pi = I - AA^D$ and $B^\pi = I - BB^D$.

Facts:

Notation: Let $A \in \mathbb{C}^{n\times n}$.

1. [BP79, Chap. 5] If the group inverse A_g exists, then it is unique.
2. $A = 0$ if and only if $A_g = 0$.
3. $(A_g)_g = A$.
4. [BG03, Chap. 4] Let a square matrix A have the full-rank factorization $A = FG$. Then A has a group inverse if and only if GF is invertible, in this case,

$$A_g = F\left[(GF)^{-1}\right]^2 G.$$

5. [CM79, Chap. 7] Let $A \in \mathbb{C}^{n\times n}$. Then the following statements are equivalent:
   (i)A is group invertible.
   (ii)A^* is group invertible.
   (iii) $\text{index}(A) \le 1$.
   (iv) $\text{rank}(A) = \text{rank}(A^2)$
   (v) $\text{range}(A) = \text{range}(A^2)$.
   (vi) $\ker(A) = \ker(A^2)$.
   (vii) $\text{range}(A) \cap \ker(A) = \{0\}$.
   (viii) $\text{range}(A) \oplus \ker(A) = \mathbb{C}^n$, where $\oplus$ is a direct sum.
   (ix) $\lim\limits_{\varepsilon\to 0}(A+\varepsilon I)^{-1}A$ exists. In this case,
$$\lim_{\varepsilon\to 0}(A+\varepsilon I)^{-1}A = AA_g, \qquad \lim_{\varepsilon\to 0}\varepsilon(A+\varepsilon I)^{-1} = I - AA_g.$$
6. [BP79, Chap. 5] If the group inverse exists, then it is equal to the Drazin inverse, i.e., $A_g = A^D$.
7. [BP79, Chap. 5] The Drazin inverse A^D exists and is unique.
8. [BG03, Chap. 4] Let $\text{index}(A) = k$ and $\text{rank}(A^k) = r$ have a Jordan canonical form
$$A = P^{-1}\begin{bmatrix} C & 0 \\ 0 & N \end{bmatrix} P,$$
   where P and C are invertible, N is nilpotent of index k. Then the Drazin inverse can be computed as
$$A^D = P^{-1}\begin{bmatrix} C^{-1} & 0 \\ 0 & 0 \end{bmatrix} P.$$
9. [CM79, Chap. 7] Let $A \in \mathbb{C}^{n\times n}$. Then the following statements are equivalent:
   (i) $\text{index}(A) = k$.
   (ii) $\text{range}(A^k) \oplus \ker(A^k) = \mathbb{C}^n$, $\text{range}(A^k)$ and $\ker(A^k)$ are complementary subspaces.
   (iii) k is the smallest nonnegative integer such that the limit $\lim\limits_{\varepsilon\to 0}(A+\varepsilon I)^{-1}A^k$ exists.
   (iv) k is the smallest nonnegative integer such that the limit $\lim\limits_{\varepsilon\to 0}\varepsilon^k(A+\varepsilon I)^{-1}$ exists.
   (v) If $\text{index}(A) = k > 0$, then $\lim\limits_{\varepsilon\to 0}(A+\varepsilon I)^{-1}A^k = (AA^D)A^{k-1}$.
   (vi) If $\text{index}(A) = k > 0$, then $\lim\limits_{\varepsilon\to 0}\varepsilon^k(A+\varepsilon I)^{-1} = (-1)^{k-1}(I - AA^D)A^{k-1}$.
10. $\text{range}(A^D) = \text{range}(A^DA) = \text{range}(A^l) = \ker(I - A^DA)$, where $l \ge \text{index}(A)$.
11. $\ker(A^D) = \ker(A^DA) = \ker(A^l) = \text{range}(I - A^DA)$, where $l \ge \text{index}(A)$.
12. $AA^D = P_{\text{range}(A^k),\ker(A^k)}$ is the oblique projector onto $\text{range}(A^k)$ along $\ker(A^k)$.
13. $I - AA^D = P_{\ker(A^k),\text{range}(A^k)}$ is the oblique projector onto $\ker(A^k)$ along $\text{range}(A^k)$.
14. [SD00] Let $A \in \mathbb{C}^{n\times n}$. Suppose that $l \ge \text{index}(A)$ and $A^l = P_{A^l}Q_{A^l}$ is a full-rank factorization of A^l. Then $A^D = P_{A^l}(Q_{A^l}AP_{A^l})^{-1}Q_{A^l}$.
15. [CM79, Chap. 7] $A^D = (A^l)_gA^{l-1} = A^l(A^{2l+1})^\dagger A^l$, where $l \ge \text{index}(A)$.
16. [BG03, Chap. 4] $A^D = \lim\limits_{\varepsilon\to 0}\left(A^{l+1}+\varepsilon^2 I\right)^{-1}A^l = \lim\limits_{\varepsilon\to 0}A^l\left(A^{l+1}+\varepsilon^2 I\right)^{-1}$. For real ε, and the approximate error is
$$\left\|A^D - (A^{l+1}+\varepsilon^2 I)^{-1}A^l\right\|_2 \le \frac{\varepsilon^2\left\|A^D\right\|_2^{l+2}}{1-\varepsilon^2\left\|A^D\right\|_2^{l+1}}, \quad l \ge \text{index}(A).$$
17. [Ji94] $A^D = \lim\limits_{\varepsilon\to 0}A^l(A+\varepsilon I)^{-(l+1)} = \lim\limits_{\varepsilon\to 0}(A+\varepsilon I)^{-(l+1)}A^l$, where $l \ge \text{index}(A)$.
18. [Wei96] $A^D = \widetilde{A}^{-1}A^l$, where $\widetilde{A} = A^{l+1}|_{\text{range}(A^l)}$ is the restriction of A^{l+1} to $\text{range}(A^l)$, and $l \ge \text{index}(A)$.

19. [CKW02] $A^D = \int_0^\infty e^{-A^k A^{(2k+1)^*} A^{k+1} t} A^k A^{(2k+1)^*} A^k dt$, where $k = \text{index}(A)$.
20. [CM79, Chap. 7] $(PAP^{-1})^D = PA^D P^{-1}$, where P is invertible.
21. $\begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix}^D = \begin{bmatrix} A^D & 0 \\ 0 & B^D \end{bmatrix}$, $\quad (A \otimes B)^D = A^D \otimes B^D, \quad \left(A^D\right)^* = (A^*)^D$.
22. [CM79, Chap. 7] Let $A \in \mathbb{C}^{m\times n}, B \in \mathbb{C}^{n\times m}$. Then $(AB)^D = A\left[(BA)^D\right]^2 B$.
23. [Wei98a] Let $A = M - N \in \mathbb{C}^{n\times n}$ with $\text{index}(A) = k$ such that $\text{range}(M) = \text{range}(A^k)$ and $\ker(M) = \ker(A^k)$ (this is called an *index splitting*). Then
$$A^D = (I - M_g N)^{-1} M_g = M_g (I - N M_g)^{-1}.$$
24. [CM79, Chap. 7] If $A, B \in \mathbb{C}^{n\times n}$ are such that $AB = BA$, then $(AB)^D = B^D A^D = A^D B^D$, $A^D B = BA^D$ and $AB^D = B^D A$.
25. [Dra58] Let $A, B \in \mathbb{C}^{n\times n}$. Assume that $AB = 0$ and $BA = 0$. Then
$$(A + B)^D = A^D + B^D.$$
26. [HWW01] If $AB = 0$, then
$$\begin{aligned}(A + B)^D = {} & \left(I - BB^D\right)\left[I + BA^D + \cdots + B^{k-1}(A^D)^{k-1}\right] A^D \\ & + B^D\left[I + B^D A + \cdots + (B^D)^{k-1} A^{k-1}\right]\left(I - AA^D\right),\end{aligned}$$
where $\max\{\text{index}(A), \text{index}(B)\} \le k \le \text{index}(A) + \text{index}(B)$.
27. [DW10, WD11] If $AB = BA$ and $\text{index}(A) = k$, then
$$\begin{aligned}(A + B)^D &= \left(I + A^D B\right)^D A^D + \left(I - AA^D\right)\sum_{i=0}^{k-1} \left(B^D\right)^{i+1} (-A)^i \\ &= \left(I + A^D B\right)^D A^D + \left(I - AA^D\right) B^D \left[I + A\left(I - AA^D\right) B^D\right]^{-1}.\end{aligned}$$
28. [CM75] Let $\{A_j\}_0^\infty$ be a sequence of matrices in $\mathbb{C}^{n\times n}$. If A_j converges to A, then A_j^D converges to A^D if and only if there exists a j_0 such that $\text{rank}\left(A_j^{k_j}\right) = \text{rank}\left(A^k\right)$ for $j \ge j_0$, where $k_j = \text{index}(A_j)$ and $k = \text{index}(A)$.
29. [CM79, Chap. 7] If $A \in \mathbb{C}^{n\times n}$, then there exists a polynomial $p(x)$ such that $A^D = p(A)$.
30. [CM79, Chap. 4] For $A \in \mathbb{C}^{n\times n}, A^D = A^\dagger$ if and only if A is an EP (or Range-Hermitian) matrix, i.e., $\text{range}(A) = \text{range}(A^*)$ (or $\ker(A) = \ker(A^*)$).
31. [COV09] $\begin{bmatrix} 0 & A \\ B & 0 \end{bmatrix}^D = \begin{bmatrix} 0 & (AB)^D A \\ B(AB)^D & 0 \end{bmatrix}$.
32. [CM79, Chap. 7] If $M = \begin{bmatrix} A & C \\ 0 & B \end{bmatrix}$, where $A \in \mathbb{C}^{n\times n}$ and $B \in \mathbb{C}^{m\times m}$ with $\text{index}(A) = k$ and $\text{index}(B) = l$, then $M^D = \begin{bmatrix} A^D & X \\ 0 & B^D \end{bmatrix}$, where
$$X = \left[\sum_{i=0}^{l-1} \left(A^D\right)^{i+2} CB^i\right]\left(I_m - BB^D\right) + \left(I_n - AA^D\right)\left[\sum_{j=0}^{k-1} A^j C\left(B^D\right)^{j+2}\right] - A^D C B^D.$$
In particular, if $C(I_m - BB^D) = 0$ and $(I_n - AA^D)C = 0$, then $M^D = \begin{bmatrix} A^D & -A^D C B^D \\ 0 & B^D \end{bmatrix}$.

33. [ZBW12a] If $M = \begin{bmatrix} A & B \\ C & 0 \end{bmatrix}$, where B is of full row rank and C is of full column rank. Then M_g exists if and only if BC is invertible. In this case,
$$M_g = \begin{bmatrix} 0 & (BC)^{-1}B \\ C(BC)^{-1} & -C(BC)^{-1}A(BC)^{-1}B \end{bmatrix}.$$
34. [CM79, Chap. 7] Let $A \in \mathbb{C}^{n\times n}$. $\lambda \in \sigma(A)$ if and only if $\lambda^{\dagger} \in \sigma\left(A^D\right)$.
35. [Wei96] Let $A \in \mathbb{C}^{n\times n}$. Then $X = A^D$ is the unique matrix satisfying
$$\operatorname{rank}\left(\begin{bmatrix} A & AA^D \\ A^DA & X \end{bmatrix}\right) = \operatorname{rank}(A).$$
36. [Wei99] Let $B = A + E$ with $\operatorname{index}(A) = 1$ and $\operatorname{rank}(A) = \operatorname{rank}(B)$, if $\|A_g\| \ \|E\| < \frac{1}{1+\|AA_g\|}$, then $\operatorname{index}(B) = 1$ and
$$\begin{aligned} B_g &= (I - AA_g)(I + EA_g)^{-1}EA_g(I + Y)^{-1}(I + A_gE)^{-1}A_g(I + Y)^{-1} \\ &\quad + (I + Y)^{-1}A_g(I + EA_g)^{-1}(I + Y)^{-1}A_gE(I + A_gE)^{-1}(I - AA_g) + (I - AA_g) \\ &\quad \times (I + EA_g)^{-1}EA_g(I + Y)^{-1}A_g(I + EA_g)^{-1}(I + Y)^{-1}A_gE(I + A_gE)^{-1}(I - AA_g) \\ &\quad + (I + Y)^{-1}(I + A_gE)^{-1}A_g(I + Y)^{-1} \\ &= \left[I + (I - AA_g)E(I + A_gE)^{-1}A_g\right](I + Y)^{-1}(I + A_gE)^{-1}A_g(I + Y)^{-1} \\ &\quad \times \left[I + A_g(I + EA_g)^{-1}E(I - AA_g)\right], \end{aligned}$$
where $Y = A_gE(I + A_gE)^{-1}(I - AA_g)(I + EA_g)^{-1}EA_g$.
37. [CH96a] Let $A \in \mathbb{C}^{n\times n}$ with $\operatorname{index}(A) = k$ and $\operatorname{rank}(A^k) = r$. Define the sequence $\{X_i\}_0^{\infty}$ by
$$X_{i+1} = 2X_i - X_iAX_i,$$
where $X_0 = \varepsilon A^k$, ε satisfies $\max\limits_{i=1,2,\ldots,r} \left|1 - \varepsilon\lambda_i^{k+1}\right| < 1$, and $\lambda_1, \lambda_2, \cdots, \lambda_r$ are the nonzero eigenvalues of A. Then $\lim\limits_{i\to\infty} X_i = A^D$.
38. [BP79, Chap. 7] Let $H \in \mathbb{C}^{n\times n}$. Then H is semi-convergent if and only if there exists a nonsingular matrix P such that
$$H = P^{-1}\begin{bmatrix} I & 0 \\ 0 & K \end{bmatrix}P,$$
where the identity matrix I is missing if $1 \notin \sigma(H)$ and $\rho(K) < 1$, or K is missing. If H is semi-convergent, then
$$\lim_{i\to\infty} H^i = I - (I - H)(I - H)_g.$$
39. [XSW10] The statements on $B = A + E \in \mathbb{C}^{n\times n}$ with $\operatorname{index}(B) = s$ are equivalent:
    (a) B is a stable perturbation of A.
    (b) For any $k, l \in \mathbb{N}$ with $k \geq s$ and $E_{k,l} = B^k - A^l$,
    $$I + (A^D)^lE_{k,l} \text{ is nonsingular}, \quad B^k\left[I + (A^D)^lE_{k,l}\right]^{-1}A^{\pi} = 0.$$
    (c) There exist $k, l \in \mathbb{N}$ with $k \geq s$ and $E_{k,l} = B^k - A^l$, such that
    $$I + (A^D)^lE_{k,l} \text{ is nonsingular}, \quad B^k\left[I + (A^D)^lE_{k,l}\right]^{-1}A^{\pi} = 0.$$

(d) B satisfies condition $(\mathcal{C}_s)$ [CRV08]: $\operatorname{range}(B^s) \cap \operatorname{range}(A^r) = \{0\}$ and $\ker(B^s) \cap \ker(A^r) = \{0\}$.

(e) $\operatorname{rank}(B^s) = \operatorname{rank}(A^r) = \operatorname{rank}(A^r B^s) = \operatorname{rank}(B^s A^r)$.

40. [XSW10] Let $B \in \mathbb{C}^{n\times n}$ be a stable perturbation of A with $\operatorname{index}(B) = s$. Then

$$\begin{aligned} B^D &= W_{k,l}^{-1} \left[I + (A^D)^{l+1} E_{k+1,l+1}\right]^{-1} A^D \left[I + (A^D)^l E_{k,l}\right] W_{k,l}, \\ B^\pi &= I - BB^D = W_{k,l}^{-1} \left[I + (A^D)^l E_{k,l}\right]^{-1} A^\pi \left[I + (A^D)^l E_{k,l}\right] W_{k,l}, \end{aligned}$$

where $W_{k,l} = (I + Y_{k,l}Z_{k,l})(I - Z_{k,l}), W_{k,l}^{-1} = (I + Z_{k,l})(I + Y_{k,l}Z_{k,l})^{-1}$ and $Y_{k,l} = \left[I + (A^D)^l E_{k,l}\right]^{-1} (A^D)^l E_{k,l}A^\pi, Z_{k,l} = A^\pi E_{k,l}(A^D)^l \left[I + E_{k,l}(A^D)^l\right]^{-1}$. Furthermore,

$$\frac{\|B^D - A^D\|}{\|A^D\|} \le \frac{\left\|W_{k,l}^{-1}\right\|}{\|A^D\|} \left(\|\Omega_1\| + \|\Omega_2\| \, \|W_{k,l}\|\right),$$

where Ω_1 and Ω_2 are independent of the choice of k and l, which are defined by

$$\begin{aligned} \Omega_1 &= A^D Y_{k,l} Z_{k,l} - Y_{k,l} Z_{k,l} A^D + Z_{k,l} A^D, \\ \Omega_2 &= \left[I + (A^D)^{l+1} E_{k+1,l+1}\right]^{-1} \left(A^D\right)^{l+1} \left(B^k - B^{k+1} A^D\right). \end{aligned}$$

Furthermore, if $\|Y_{k,l}Z_{k,l}\| < 1$, then

$$\begin{aligned} \frac{\|B^D - A^D\|}{\|A^D\|} &\le \frac{1 + \|Z_{k,l}\|}{(1 - \|Y_{k,l}Z_{k,l}\|) \|A^D\|} \left(\|\Omega_1\| + \varepsilon \|\Omega_2\|\right) \\ &\le \frac{1 + \|Z_{k,l}\|}{(1 - \|Y_{k,l}Z_{k,l}\|) \|A^D\|} \left(\gamma \|A^D\| + \varepsilon \|\Omega_2\|\right), \end{aligned}$$

where $\varepsilon = 1 + \|Z_{k,l}\| + \|Y_{k,l}Z_{k,l}\|$, $\gamma = (2\|Y_{k,l}Z_{k,l}\| + \|Z_{k,l}\|) \left\|A^D\right\|$.

41. Let $B = A + E \in \mathbb{C}^{n\times n}$ with $\operatorname{index}(A) = k$ and $I + A^D E$ be invertible.

(a) [Wei00a] If $AA^D E = E$, then $\operatorname{range}(B^D) = \operatorname{range}(A^D)$ and

$$B^D = X + \sum_{i=0}^{k-1} X^{i+2} E \left(I - AA^D\right) A^i,$$

where $X = A^D - A^D E(I + A^D E)^{-1} A^D = (I + A^D E)^{-1} A^D$.

(b) [Mey80, Wei00a] If $EAA^D = E$, then $\ker(B^D) = \ker(A^D)$ and

$$B^D = Y + \sum_{i=0}^{k-1} \left(I - AA^D\right) A^i E Y^{i+2},$$

where $Y = A^D - A^D(I + EA^D)^{-1} EA^D = A^D(I + EA^D)^{-1}$.

(c) [WW97] If $AA^DE = EAA^D = E$, then $BB^D = AA^D$ and

$$B^D = \left(I + A^DE\right)^{-1} A^D = A^D \left(I + EA^D\right)^{-1}.$$

(d) [WWQ04, Chap. 8] The condition number of the Drazin inverse

$$Cond_P(A) = \lim_{\epsilon \to 0} \sup_{\substack{\|E\|_P \leq \epsilon \|A\|_P \\ AA^DE = EAA^D = E}} \frac{\left\|(A+E)^D - A^D\right\|_P}{\epsilon \left\|A^D\right\|_P},$$

satisfies $Cond_P(A) = \|A\|_P \left\|A^D\right\|_P$, where $\|A\|_P = \left\|PAP^{-1}\right\|_2$, $\left\|A^D\right\|_P = \left\|PA^DP^{-1}\right\|_2$, and P is the transformation matrix of the Jordan canonical form for A.

42. [WW00c] Let $B = A + E$ with index$(A) = k$ and index$(B) = j$. Let $l = \max\{k, j\}$ and $E(l) = B^l - A^l$. If $\|EA^D\| < 1$, then

$$B^D = \left(I + A^DE\right)^{-1} A^D = A^D \left(I + EA^D\right)^{-1}$$

if and only if

$$\operatorname{rank}\left(B^j\right) = \operatorname{rank}\left(A^k\right), \quad AA^DE(l) = E(l)AA^D = E(l).$$

43. [Wan89] Let $A \in \mathbb{C}^{n\times n}$, index$(A) = k$, rank$(A^k) = r$, and $U, V^* \in \mathbb{C}_{n-r}^{n\times(n-r)}$ be matrices whose columns form bases for ker $\left(A^k\right)$ and ker $\left(A^{k^*}\right)$, respectively. Then $\mathcal{A} = \begin{bmatrix} A & U \\ V & 0 \end{bmatrix}$ is nonsingular and

$$\mathcal{A}^{-1} = \begin{bmatrix} A^D & U(VU)^{-1} \\ (VU)^{-1}V & -(VU)^{-1}VAU(VU)^{-1} \end{bmatrix}.$$

44. [BG03, Chap. 4] Suppose $A \in \mathbb{C}^{n\times n}$ and perform a sequence of full rank factorizations:

$$A = B_1C_1, \qquad C_iB_i = B_{i+1}C_{i+1}, \quad (i = 1, 2, \ldots, k-1)$$

where k is the index of A. Then

$$A^D = B_1B_2 \cdots B_k(C_kB_k)^{-1}C_kC_{k-1} \cdots C_1.$$

45. [CM79, Chap. 7] Let $A \in \mathbb{C}^{r\times r}$ and $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$. If rank$(M)$ = rank$(A) = r$, then index$(M) = 1$ if and only if S^{-1} exists, where $S = I + A^{-1}BCA^{-1}$. When index$(M) = 1, M_g$ is given by

$$M_g = \begin{bmatrix} I \\ CA^{-1} \end{bmatrix} (SAS)^{-1} \begin{bmatrix} I & A^{-1}B \end{bmatrix} = \begin{bmatrix} A \\ C \end{bmatrix} \left(A^2 + BC\right)^{-1} A \left(A^2 + BC\right)^{-1} \begin{bmatrix} A & B \end{bmatrix}.$$

46. [Wei98a, WW00a, WW01a] The general solution of the singular linear equations

$$A\mathbf{x} = \mathbf{b}, \qquad \left(\mathbf{b} \in \operatorname{range}(A^k), \quad k = \operatorname{index}(A)\right)$$

is $\mathbf{x} = A^D\mathbf{b} + A^{k-1}(I - A^DA)\mathbf{z}$, $\mathbf{z}$ is an arbitrary vector. In particular, the minimal P-norm solution of this equation is presented by $\mathbf{x} = A^D\mathbf{b}$, where P is the transformation matrix of the Jordan canonical form for A and $\|\mathbf{x}\|_P = \|P\mathbf{x}\|_2$.

Examples:

1. [CM79, Example 7.2.2] Let $A = \begin{bmatrix} 2 & 0 & 0 \\ -1 & 1 & 1 \\ -1 & -1 & -1 \end{bmatrix}$.

   We can compute A^D by the Jordan canonical form

$$PAP^{-1} = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & -1 & -1 \end{bmatrix} = \begin{bmatrix} C & 0 \\ 0 & N \end{bmatrix},$$

   where

$$C = 2, \qquad N = \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix} \left(N^2 = 0\right), \qquad P = \frac{1}{8}\begin{bmatrix} 1 & 0 & 0 \\ 8 & 8 & 0 \\ 0 & 0 & 8 \end{bmatrix}, \qquad P^{-1} = \begin{bmatrix} 8 & 0 & 0 \\ -8 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

   Then

$$A^D = P^{-1}\begin{bmatrix} C^{-1} & 0 \\ 0 & 0 \end{bmatrix} P = P^{-1}\begin{bmatrix} \frac{1}{2} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} P = \frac{1}{2}\begin{bmatrix} 1 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

2. We consider a singular M-matrix [CNS97, WW00d],

$$A = \begin{bmatrix} 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & -1 & 1 & -1 & 0 & 0 & 0 & 0 \\ -1 & -1 & -1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & -1 & -1 & -1 \\ 0 & 0 & 0 & 0 & -1 & 1 & -1 & -1 \\ 0 & 0 & 0 & -1 & 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 \end{bmatrix}.$$

   Here $\sigma(A) = \{0,0,0,0,2,2,2,2\}$ and $\text{index}(A) = 4$. We can compute the Drazin inverse A^D by using Fact 37 with $\varepsilon = 0.001$. After 11 iterations we get that

$$A^D = \begin{bmatrix} \frac{1}{4} & -\frac{1}{4} & 0 & 0 & 0 & 0 & 0 & 0 \\ -\frac{1}{4} & \frac{1}{4} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{4} & -\frac{1}{4} & 0 & 0 & 0 & 0 \\ 0 & 0 & -\frac{1}{4} & \frac{1}{4} & 0 & 0 & 0 & 0 \\ 0 & 0 & -\frac{1}{16} & \frac{1}{16} & \frac{1}{4} & -\frac{1}{4} & 0 & 0 \\ 0 & 0 & -\frac{1}{16} & \frac{1}{16} & -\frac{1}{4} & \frac{1}{4} & 0 & 0 \\ \frac{1}{16} & \frac{1}{16} & -\frac{1}{16} & -\frac{1}{16} & 0 & 0 & \frac{1}{4} & -\frac{1}{4} \\ -\frac{1}{16} & -\frac{1}{16} & \frac{3}{16} & -\frac{1}{16} & 0 & 0 & -\frac{1}{4} & \frac{1}{4} \end{bmatrix}.$$

27.4 Outer Inverse

Definitions:

Let $A \in \mathbb{C}^{m \times n}$.

If $X \in \mathbb{C}^{n \times m}$ satisfies $AXA = A$, then X is an **inner inverse** or **{1}-inverse** of A.

If $X \in \mathbb{C}^{n\times m}$ satisfies $XAX = X$, then X is an **outer inverse** or **{2}-inverse** of A.

If X is both an inner and an outer inverse of A, then X is a **reflexive generalized inverse**.

Let $A \in \mathbb{C}_r^{m\times n}, T \subseteq \mathbb{C}^n, S \subseteq \mathbb{C}^m$, $\dim(T) = \dim(S^\perp) \leq r$. An outer inverse X of A such that range$(X) = T$, and $\ker(X) = S$ is the **outer inverse with prescribed range T and null space S** and is denoted by $A^{(2)}_{T,S}$ [BG03, Chap. 2].

Facts: Notation: Let $A \in \mathbb{C}_r^{m\times n}, T \subseteq \mathbb{C}^n, S \subseteq \mathbb{C}^m$, $\dim(T) = \dim(S^\perp) \leq r$.

1. A has a outer inverse X such that range$(X) = T$, and $\ker(X) = S$ if and only if $AT \oplus S = \mathbb{C}^m$, in which case X is unique.
2. If A has an outer inverse X such that range$(X) = T$, $\ker(X) = S$, and $\dim(T) = \dim(S^\perp) = r$, then the outer inverse $A^{(2)}_{T,S}$ is a reflexive generalized inverse (and can be denoted $A^{(1,2)}_{T,S}$).
3. The common important generalized inverses, such as the Moore-Penrose inverse $A^\dagger$, the weighted Moore-Penrose inverse $A^\dagger_{M,K}$ [Eld82], the Drazin inverse A^D, the group inverse A_g, the Bott-Duffin inverse $A^{(-1)}_{(L)}$ [BG03, LWW09], the generalized Bott-Duffin inverse $A^{(\dagger)}_{(L)}$ [Che90], and the W-weighted Drazin inverse $A_{d,W}$ [RW02], can be reduced to the outer inverse X of A with prescribed range T and null space S [Che93, Che05], i.e.,
$$XAX = X, \quad \text{range}(X) = T, \quad \ker(X) = S.$$
4. [BG03, Chap. 2] Let $A \in \mathbb{C}_r^{m\times n}$, T be a subspace of $\mathbb{C}^n$ of dimension r, and S be a subspace of $\mathbb{C}^m$ of dimension $m - r$. Then the following statements are equivalent:
(i) $AT \oplus S = \mathbb{C}^m$.
(ii) range$(A) \oplus S = \mathbb{C}^m$ and $\ker(A) \oplus T = \mathbb{C}^n$.
(iii) There exists an $X \in A\{1, 2\}$ such that range$(X) = T$ and $\ker(X) = S$.
5. [BG03, Chap. 2] $A^{(2)}_{T,S} = (P_{S^\perp} A P_T)^\dagger, \quad \left(A^{(2)}_{T,S}\right)^* = (A^*)^{(2)}_{S^\perp,T^\perp}$.
6. [Che93] $AT \oplus S = \mathbb{C}^m$ is equivalent to $A^*S^\perp \oplus T^\perp = \mathbb{C}^n$.
7. [BG03, Chap. 2] $A^{(1,2)}_{T,S}$ is the unique matrix X satisfying three matrix equations:
$$AX = P_{L,S}, \quad XA = P_{T,M}, \quad XP_{L,S} = X.$$
8. [BG03, Chap. 2] If A is square and $A = FG$ is a full-rank factorization, A has a reflexive generalized inverse X with range$(X) =$ range(A) and $\ker(X) = \ker(A)$ if and only if GF is nonsingular, in which case,
$$X = F\left[(GF)^{-1}\right]^2 G.$$
9. [WW01d] Let $A = M - N \in \mathbb{C}^{m\times n}, T \subseteq \mathbb{C}^n, S \subseteq \mathbb{C}^m, AT \oplus S = \mathbb{C}^m$, and A be a (T, S) splitting of A such that range$(M) = AT$ and $\ker(M) = (A^*S^\perp)^\perp$, then $M^{(1,2)}_{T,S}$ exists and
$$A^{(2)}_{T,S} = \left(I_n - M^{(1,2)}_{T,S} N\right)^{-1} M^{(1,2)}_{T,S} = M^{(1,2)}_{T,S}\left(I_m - NM^{(1,2)}_{T,S}\right)^{-1}.$$
10. [Wei98b] Suppose A has a generalized inverse $A^{(2)}_{T,S}$. Then $X = A^{(2)}_{T,S}$ is the unique matrix satisfying
$$\text{rank}\left(\begin{bmatrix} A & AA^{(2)}_{T,S} \\ A^{(2)}_{T,S}A & X \end{bmatrix}\right) = \text{rank}(A).$$

11. If $A \in \mathbb{C}^{m\times n}$ has rank r, there are nonsingular matrices P and Q such that
$$A = P\begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} Q.$$
Then the set of inner inverses of A is
$$\left\{ Q^{-1}\begin{bmatrix} I_r & X \\ Y & Z \end{bmatrix} P^{-1} : X \in \mathbb{C}^{r\times(n-r)}, Y \in \mathbb{C}^{(m-r)\times r}, Z \in \mathbb{C}^{(m-r)\times(n-r)} \right\}.$$

12. If $A^{(2)}_{T,S}$ exists, and suppose that $G \in \mathbb{C}^{n\times m}$ such that $\mathrm{range}(G) = T$ and $\ker(G) = S$.
(i) [Wei98b] Then the outer inverse has the expressions,
$$A^{(2)}_{T,S} = (GA)_g G = G(AG)_g, \quad \text{and} \quad A^{(2)}_{T,S} = \widetilde{A}^{-1}G,$$
with
$$A^{(2)}_{T,S} = \lim_{\varepsilon\to 0}(GA + \varepsilon I_n)^{-1}G = \lim_{\varepsilon\to 0} G(AG + \varepsilon I_m)^{-1},$$
where $\widetilde{A} = GA|_{\mathrm{range}(G)}$ is the restriction of GA to $\mathrm{range}(G)$.
(ii) [Che05, CC00] For any $\epsilon > 0$, $\lambda_k(GA)$ is an eigenvalue of GA, there exists a matrix norm $\|\cdot\|_*$ such that
$$\left\| A^{(2)}_{T,S} - (GA + \varepsilon I_n)^{-1}G \right\|_* \le \left(\frac{|\varepsilon|}{\min\limits_{\lambda_k(GA)\neq 0} |\varepsilon + \lambda_k(GA)|} + \epsilon \right) \left\| A^{(2)}_{T,S} \right\|_* .$$
Furthermore, if GA (or AG) is Hermitian nonnegative definite matrix and $\varepsilon > 0$, then
$$\left\| A^{(2)}_{T,S} - (GA + \varepsilon I_n)^{-1}G \right\|_2 \le \frac{\varepsilon}{\varepsilon + \lambda_{\min}} \left\| A^{(2)}_{T,S} \right\|_2 ,$$
where $\lambda_{\min}$ is the smallest positive eigenvalue of GA (or AG).
(iii) [YW09, Che05] $A^{(2)}_{T,S} = (GA)^{(1,5)}G = G(AG)^{(1,5)} = G(GAG)^{(1)}G$, where $(GA)^{(1,5)}$ is a $\{1,5\}$-inverse of GA, $(AG)^{(1,5)}$ is a $\{1,5\}$-inverse of AG and $(GAG)^{(1)}$ is a $\{1\}$-inverse of GAG.
(iv) [WD03, WWQ04] Let $G = PQ$ be a full rank decomposition of G. Then
$$A^{(2)}_{T,S} = P(QAP)^{-1}Q,$$
where $T = \mathrm{range}(G) = \mathrm{range}(P)$, and $S = \ker(G) = \ker(Q)$.

13. If $A^{(2)}_{T,S}$ exists, and there exists $G \in \mathbb{C}^{n\times m}$ such that $\mathrm{range}(G) = T$ and $\ker(G) = S$.
(i) [WD03] A, G and the outer inverse $A^{(2)}_{T,S}$ have the following algebraic structure:
$$A = Q^{-1}\begin{bmatrix} A_{11} & 0 \\ 0 & A_{22} \end{bmatrix} P, \quad G = P^{-1}\begin{bmatrix} G_{11} & 0 \\ 0 & 0 \end{bmatrix} Q, \quad A^{(2)}_{T,S} = P^{-1}\begin{bmatrix} A_{11}^{-1} & 0 \\ 0 & 0 \end{bmatrix} Q,$$
where A_{11}, $G_{11} \in \mathbb{C}^{r\times r}$, $P \in \mathbb{C}^{n\times n}$, $Q \in \mathbb{C}^{m\times m}$, and P, Q, A_{11}, G_{11} are all invertible.
(ii) [Wei03] $A^{(2)}_{T,S} = \int_0^\infty e^{-G(GAG)^*GAt} G(GAG)^*G dt$.
If the real part of any nonzero eigenvalue λ of GA satisfies $\mathrm{Re}(\lambda) > 0$, then
$$A^{(2)}_{T,S} = \int_0^\infty e^{-GAt} G dt.$$

14. Let $A, E \in \mathbb{C}^{m\times n}, T \subseteq \mathbb{C}^n, S \subseteq \mathbb{C}^m, AT \oplus S = \mathbb{C}^m$. Suppose $\operatorname{range}(E) \subseteq AT, \operatorname{range}(E^*) \subseteq A^*S^\perp$.
(i) [WW01b] If $I_n + A^{(2)}_{T,S}E$ is invertible, then

$$(A+E)^{(2)}_{T,S} = \left(I_n + A^{(2)}_{T,S}E\right)^{-1} A^{(2)}_{T,S} = A^{(2)}_{T,S}\left(I_m + EA^{(2)}_{T,S}\right)^{-1}.$$

(ii) [WZ03] The condition number $Cond(A) = \lim\limits_{\epsilon\to 0} \sup\limits_{\|E\|_{QP}\leq \epsilon\|A\|_{QP}} \frac{\left\|(A+E)^{(2)}_{T,S} - A^{(2)}_{T,S}\right\|_{PQ}}{\epsilon\left\|A^{(2)}_{T,S}\right\|_{PQ}}$, satisfies $Cond(A) = \|A\|_{QP}\left\|A^{(2)}_{T,S}\right\|_{PQ}$, where $\|A\|_{QP} = \left\|QAP^{-1}\right\|_2, \left\|A^{(2)}_{T,S}\right\|_{PQ} = \left\|PA^{(2)}_{T,S}Q^{-1}\right\|_2$.

15. [Che05, Chap. 5] Let $A \in \mathbb{C}_r^{m\times n}, T \subseteq \mathbb{C}^n, S \subseteq \mathbb{C}^m$, $\dim(T) = \dim(S^\perp) \leq r$ and $AT \oplus S = \mathbb{C}^m$. Suppose that $\{A_k\} \subset \mathbb{C}^{m\times n}$, $\{T_k\}, \{S_k\}$ are the subspaces of $\mathbb{C}^n$ and $\mathbb{C}^m$, respectively. Let $A_k \to A, T_k \to T, S_k \to S$. Then $(A_k)^{(2)}_{T_k,S_k} \to A^{(2)}_{T,S}$ $(k\to\infty)$, if and only if there exists k_0 such that for all $k \geq k_0$, we have

$$\dim(T_k) = \dim(S_k^\perp), \quad AT_k \oplus S_k = \mathbb{C}^m, \quad \dim(T_k) = \dim(T) \text{ (or } \dim(S_k) = \dim(S)).$$

16. [Che05, Chap. 5] Let $A, \widetilde{A} \in \mathbb{C}^{m\times n}$, $T, \widetilde{T}$ be the subspaces of $\mathbb{C}^n$ and $S, \widetilde{S}$ be the subspaces of $\mathbb{C}^m$. Suppose $\dim(\widetilde{T}) = \dim(\widetilde{S}^\perp) = \dim(T) = \dim(S^\perp)$. There exist $\widetilde{A}^{(2)}_{\widetilde{T},\widetilde{S}}$ and $A^{(2)}_{T,S}$, and $\dim(\widetilde{T}) = \dim(T) < \min\{m,n\}$, with

$$\frac{\left\|\widetilde{A}^{(2)}_{\widetilde{T},\widetilde{S}} - A^{(2)}_{T,S}\right\|}{\left\|\widetilde{A}^{(2)}_{\widetilde{T},\widetilde{S}}\right\|} \leq \frac{1+\sqrt{5}}{2}\|A\|\left\|A^{(2)}_{T,S}\right\|\left(\left\|P_{\widetilde{T}} - P_T\right\| + \left\|P_{\widetilde{S}} - P_S\right\| + \frac{\left\|\widetilde{A} - A\right\|}{\|A\|}\right).$$

17. [Che93] Let $A \in \mathbb{C}_r^{m\times n}, T \subseteq \mathbb{C}^n, S \subseteq \mathbb{C}^m$, $\dim(T) = \dim(S^\perp) \leq r$ and $AT \oplus S = \mathbb{C}^m$. Let B and C^* be of full column ranks such that $\operatorname{range}(B) = S$ and $\ker(C) = T$. Then the bordered matrix $\mathcal{A} = \begin{bmatrix} A & B \\ C & 0 \end{bmatrix}$ is nonsingular and

$$\mathcal{A}^{-1} = \begin{bmatrix} A^{(2)}_{T,S} & \left(I_n - A^{(2)}_{T,S}A\right)C^\dagger \\ B^\dagger\left(I_m - AA^{(2)}_{T,S}\right) & B^\dagger\left(AA^{(2)}_{T,S}A - A\right)C^\dagger \end{bmatrix}.$$

Furthermore, let U and V^* be of full column ranks such that $\operatorname{range}(U) = (A^*S^\perp)^\perp$ and $\ker(V) = AT$. Then

$$\mathcal{A}^{-1} = \begin{bmatrix} A^{(2)}_{T,S} & U(CU)^{-1} \\ (VB)^{-1}V & -(VB)^{-1}VAU(CU)^{-1} \end{bmatrix}.$$

18. [Che93] Let $A \in \mathbb{C}_r^{m\times n}, T \subseteq \mathbb{C}^n, S \subseteq \mathbb{C}^m$, $\dim(T) = \dim(S^\perp) = r$ and $\operatorname{range}(A) \oplus S = \mathbb{C}^m$, $\ker(A) \oplus T = \mathbb{C}^n$. Let B and C^* be of full column ranks such that $\operatorname{range}(B) = S$ and $\ker(C) = T$. Then the bordered matrix $\mathcal{A} = \begin{bmatrix} A & B \\ C & 0 \end{bmatrix}$ is nonsingular and

$$\mathcal{A}^{-1} = \begin{bmatrix} A^{(1,2)}_{T,S} & \left(I_n - A^{(1,2)}_{T,S}A\right)C^\dagger \\ B^\dagger\left(I_m - AA^{(1,2)}_{T,S}\right) & 0 \end{bmatrix}.$$

Furthermore, let U and V^* be of full column ranks such that range$(U) = \ker(A)$ and $\ker(V) =$ range(A). Then

$$\mathcal{A}^{-1} = \begin{bmatrix} A_{T,S}^{(1,2)} & U(CU)^{-1} \\ (VB)^{-1}V & 0 \end{bmatrix}.$$

19. [Che93] $A_{T,S}^{(2)}\mathbf{b}$ is the solution of the restricted equations $A\mathbf{x} = \mathbf{b}, \mathbf{x} \in T, \mathbf{b} \in AT$.
20. [YW09] Let $A \in \mathbb{C}^{m\times n}$ and $T \subseteq \mathbb{C}^n$, $S \subseteq \mathbb{C}^m$. Suppose that there exists a matrix $G \in \mathbb{C}^{n\times m}$ for which range$(G) = T$ and $\ker(G) = S$, and $A_{T,S}^{(2)}$ exists. Then

$$A_{T,S}^{(2)} = \sum_{(\alpha,\beta)\in\mathcal{N}(A)} \lambda[\alpha,\beta]A\widehat{[\alpha,\beta]}^{-1}, \quad A_{T,S}^{(2)}\mathbf{b} = \sum_{(\alpha,\beta)\in\mathcal{N}(A)} \lambda[\alpha,\beta]A[\widehat{\alpha,\beta]^{-1}}\mathbf{b}[\alpha],$$

where $\lambda[\alpha,\beta] = \frac{\det(G[\beta,\alpha])\det(A[\alpha,\beta])}{\sum\limits_{(\gamma,\delta)\in\mathcal{N}(A)}\det(G[\delta,\gamma])\det(A[\gamma,\delta])}$.

27.5 Conjectures and Open Questions

1. [CM79, Chap. 7],[Cam83] Let $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$, where A and C are square. There is no known representation for M^D with A, B, C, and D arbitrary.
2. [HL80, WW01c] What is the optimal perturbation bound of the Drazin inverse, oblique projections, and applications to the Hill cryptographic system?
3. [ZBW12a, ZBW12b] What is the Drazin inverse for block matrices and some related sign analysis?
4. [DD06, IM95, QZL05, Ste11, Sun87, Szy06] What is the metric between the oblique projectors and the Drazin inverse?
5. [CKNS10, Mey75, Mey80] What is the optimal perturbation bound of the group inverse and its applications to the finite Markov chain?
6. [AH03, SW12, WD11, WLB06] What is the sharp relative perturbation bounds for the eigenvalues of diagonalizable and singular matrices with respect to the group inverse?
7. [BC10, BDGL09, CDW06, CDW07, Ste90] What is the smooth analysis for the Moore-Penrose inverse of the rank-deficient case and the Drazin inverse?
8. [BC10, CDW06, CDW07] What is the componentwise and mixed perturbation for the Moore-Penrose inverse of the rank-deficient case and the Drazin inverse?

Alberto Borobia
UNED

In general, an **inverse eigenvalue problem** (IEP) consists of the construction of a matrix with prescribed structural and spectral constraints. This is a two-level problem: (1) on a theoretical level the target is to determine if the IEP is solvable, that is, to find necessary and sufficient conditions for the existence of at least one **solution matrix** (a matrix with the given constraints); and (2) on a practical level, the target is the effective construction of a solution matrix when the IEP is solvable. IEPs are classified into different types according to the specific constraints. We will consider three topics: IEPs with prescribed entries, nonnegative IEPs, and affine parameterized IEPs. Other important topics include pole assignment problems, Jacobi IEPs, inverse singular value problems, etc. For interested readers, we refer to the survey [CG02] where an account of IEPs with applications and extensive bibliography can be found.

28.1 IEPs with Prescribed Entries

The underlying question for an IEP with prescribed entries (PEIEPs) is to understand how the prescription of some entries of a matrix can have repercussions on its spectral properties. A classical result on this subject is the Schur–Horn Theorem allowing the construction of a real symmetric matrix with prescribed diagonal, prescribed eigenvalues, and subject to some restrictions (see Fact 1 next). Here we consider PEIEPs that require finding a matrix with some prescribed entries and with prescribed eigenvalues or characteristic polynomial; no structural constraints are imposed on the solution matrices.

Most of the facts of Sections 28.1 and 28.2 appear in [IC00], an excellent survey that describes finite step procedures for constructing solution matrices.

Definitions:

An **IEP with prescribed entries** (PEIEP) has the following standard formulation:

Given:

(a) A field F.
(b) n elements $\lambda_1, \ldots, \lambda_n$ of F (respectively, a monic polynomial $f \in F[x]$ of degree n).
(c) t elements $p_1, \ldots, p_t$ of F.
(d) A set $\mathcal{Q} = \{(i_1, j_1), \ldots, (i_t, j_t)\}$ of t positions of an $n \times n$ matrix.

Find: A matrix $A = [a_{ij}] \in F^{n\times n}$ with $a_{i_k j_k} = p_k$ for $1 \leq k \leq t$ and such that $\sigma(A) = \{\lambda_1, \ldots, \lambda_n\}$ (respectively, such that $p_A(x) = f$).

Facts: [IC00]

1. (Schur–Horn Theorem) Given any real numbers $\lambda_1 \geq \cdots \geq \lambda_n$ and $d_1 \geq \cdots \geq d_n$ satisfying

$$\sum_{i=1}^{k} \lambda_i \geq \sum_{i=1}^{k} d_i \quad \text{for } k = 1, \ldots, n-1 \quad \text{and} \quad \sum_{i=1}^{n} \lambda_i = \sum_{i=1}^{n} d_i,$$

   there exists a real symmetric $n \times n$ matrix with diagonal $(d_1, \ldots, d_n)$ and eigenvalues $\lambda_1, \ldots, \lambda_n$; and any Hermitian matrix satisfies these conditions on its eigenvalues and diagonal entries.
2. A finite step algorithm is provided in [CL83] for the construction of a solution matrix for the Schur–Horn Theorem.
3. Consider the following classes of PEIEPs:

(1.1)	F	$\lambda_1, \ldots, \lambda_n$	$p_1, \ldots, p_{n-1}$	$\lvert\mathcal{Q}\rvert = n-1$
(1.2)	F	$f = x^n + c_1x^{n-1} + \cdots + c_n$	$p_1, \ldots, p_{n-1}$	$\lvert\mathcal{Q}\rvert = n-1$
(2.1)	F	$\lambda_1, \ldots, \lambda_n$	$p_1, \ldots, p_n$	$\lvert\mathcal{Q}\rvert = n$
(2.2)	F	$f = x^n + c_1x^{n-1} + \cdots + c_n$	$p_1, \ldots, p_n$	$\lvert\mathcal{Q}\rvert = n$
(3.1)	F	$\lambda_1, \ldots, \lambda_n$	$p_1, \ldots, p_{2n-3}$	$\lvert\mathcal{Q}\rvert = 2n-3$

   (a) [Oli73a] Each PEIEP of class (1.1) is solvable.

   (b) [Dia74] Each PEIEP of class (1.2) is solvable except if all off-diagonal entries in one row or column are prescribed to be zero and f has no root on F.

   (c) [Oli73b] Each PEIEP of class (2.1) is solvable with the following exceptions: (1) all entries in the diagonal are prescribed and their sum is different from $\lambda_1 + \cdots + \lambda_n$; (2) all entries in one row or column are prescribed, with zero off-diagonal entries and diagonal entry different from $\lambda_1, \ldots, \lambda_n$; and (3) $n = 2$, $\mathcal{Q} = \{(1, 2), (2, 1)\}$, and $x^2 - (\lambda_1 + \lambda_2)x + p_1p_2 + \lambda_1\lambda_2 \in F[x]$ is irreducible over F.

   (d) [Zab86] For $n > 4$, each PEIEP of class (2.2) is solvable with the following exceptions: (1) all entries in the diagonal are prescribed and their sum is different from -c_1; (2) all entries in a row or column are prescribed, with zero off-diagonal entries and diagonal entry which is not a root of f; and (3) all off-diagonal entries in one row or column are prescribed to be zero and f has no root on F. The case $n \leq 4$ is solved but there are more exceptions.

   (e) [Her83] Each PEIEP of class (3.1) is solvable with the following exceptions: (1) all entries in the diagonal are prescribed and their sum is different from $\lambda_1 + \cdots + \lambda_n$; and (2) all entries in one row or column are prescribed, with zero off-diagonal entries and diagonal entry different from $\lambda_1, \ldots, \lambda_n$.

   (f) [Her83] The result for PEIEPs of class (3.1) cannot be improved to $|\mathcal{Q}| > 2n-3$ since a lot of specific nonsolvable situations appear and, therefore, a closed result seems to be quite inaccessible.

   (g) A gradient flow approach is proposed in [CDS04] to explore the existence of solution matrices when the set of prescribed entries has arbitrary cardinality.

4. The important case $\mathcal{Q} = \{(i,j) : i \neq j\}$ is discussed in Section 28.9.
5. Let $\{p_{ij} : 1 \leq i \leq j \leq n\}$ be a set of $\frac{n^2+n}{2}$ elements of a field F. Define the set $\{r_1, \ldots, r_s\}$ of all those integers r such that $p_{ij} = 0$ whenever $1 \leq i \leq r < j \leq n$. Assume that $0 = r_0 < r_1 < \cdots < r_s < r_{s+1} = n$ and define $\beta_t = \sum_{r_{t-1} < k \leq r_t} p_{kk}$ for $t = 1, \ldots, s+1$. The following PEIEPs have been solved:

   (a) [BGR90] Let $\lambda_1, \ldots, \lambda_n$ be n elements of F. Then there exists $A = [a_{ij}] \in F^{n \times n}$ with $a_{ij} = p_{ij}$ for $1 \leq i \leq j \leq n$ and $\sigma(A) = \{\lambda_1, \ldots, \lambda_n\}$ if and only if $\{1, \ldots, n\}$ has a partition $N_1 \cup \cdots \cup N_{s+1}$ such that $|N_t| = r_t - r_{t-1}$ and $\sum_{k \in N_t} \lambda_k = \beta_t$ for each $t = 1, \ldots, s+1$.

   (b) [Sil93] Let $f \in F[x]$ be a monic polynomial of degree n. Then there exists $A = [a_{ij}] \in F^{n \times n}$ with $a_{ij} = p_{ij}$ for $1 \leq i \leq j \leq n$ and $p_A(x) = f$ if and only if $f = f_1 \cdots f_{s+1}$, where $f_t = x^{r_t - r_{t-1}} - \beta_t \, x^{r_t - r_{t-1} - 1} + \cdots \in F[x]$ for $t = 1, \ldots, s+1$.

6. [Fil69] Let $d_1, \ldots, d_n$ be elements of a field F, and let $A \in F^{n \times n}$ with $A \neq \lambda I_n$ for all $\lambda \in F$ and $\operatorname{tr}(A) = \sum_{i=1}^n d_i$. Then A is similar to a matrix with diagonal $(d_1, \ldots, d_n)$.
7. [BCS10] If F is an integral domain (instead of a field), then each PEIEP of class (3.1) is solvable if there is at least one unprescribed entry in each row, in each column, and in the diagonal. A finite algorithm is provided to construct a solution matrix.

Examples:

1. [Oli73b] Let F be a field. Let $\lambda_1, \ldots, \lambda_n \in F$ and $p_1, \ldots, p_n \in F$ with $\sum_{i=1}^n \lambda_i = \sum_{i=1}^n p_i$. Let $\mathcal{Q} = \{(1,1), \ldots, (n,n)\}$. Then $A = [a_{ij}] \in F^{n \times n}$ with

$$\begin{aligned} a_{ii} &= p_i\,, & a_{ij} &= 0 \quad \text{if} \quad i \leq j-2\,, \\ a_{i,i+1} &= \sum_{k=1}^{i} \lambda_k - \sum_{k=1}^{i} p_k\,, & a_{ij} &= p_j - \lambda_{j+1} \quad \text{if} \quad i > j\,, \end{aligned}$$

   has diagonal $(p_1, \ldots, p_n)$ and its spectrum is $\sigma(A) = \{\lambda_1, \ldots, \lambda_n\}$.

28.2 PEIEPs of 2×2 Block Type

In the 1970s, de Oliveira posed the problem of determining all possible spectra of a 2×2 block matrix A or all possible characteristic polynomials of A or all possible invariant polynomials of A when some of the blocks are prescribed and the rest vary (*invariant polynomial* is a synonym for *invariant factor*, cf. Section 6.7).

Definitions:

Let F be a field and let A be the 2×2 block matrix

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \in F^{n \times n} \quad \text{with } A_{11} \in F^{l \times l} \text{ and } A_{22} \in F^{m \times m}.$$

Notation:

- $\deg(f)$: degree of $f \in F[x]$.

- $g|f$: polynomial g divides the polynomial f.
- $ip(B)$: invariant polynomials of the square matrix B.

Facts: [IC00]

1. [Oli71] Let A_{11} and a monic polynomial $f \in F[x]$ of degree n be given. Let $ip(A_{11}) = g_1|\cdots|g_l$. Then $p_A(x) = f$ is possible except if $l > m$ and $g_1 \cdots g_{l-m}$ is not a divisor of f.
2. [Sa79], [Tho79] Let A_{11} and n monic polynomials $f_1, \ldots, f_n \in F[x]$ with $f_1|\cdots|f_n$ and $\sum_{i=1}^{n} \deg(f_i) = n$ be given. Let $ip(A_{11}) = g_1|\cdots|g_l$. Then $ip(A) = f_1|\cdots|f_n$ is possible if and only if $f_i \,|\, g_i \,|\, f_{i+2m}$ for each $i = 1, \ldots, l$ where $f_k = 0$ for $k > n$.
3. [Oli75] Let A_{12} and a monic polynomial $f \in F[x]$ of degree n be given. Then $p_A(x) = f$ is possible except if $A_{12} = 0$ and f has no divisor of degree l.
4. [Zab89], [Sil90] Let A_{12} and n monic polynomials $f_1, \ldots, f_n \in F[x]$ with $f_1|\cdots|f_n$ and $\sum_{i=1}^{n} \deg(f_i) = n$ be given. Let $r = \operatorname{rank}(A_{12})$ and s the number of polynomials in $f_1, \ldots, f_n$ which are different from 1. Then $ip(A) = f_1|\cdots|f_n$ is possible if and only if $r \leq n - s$ with the following exceptions:
   (a) $r = 0$ and $\prod_{i=1}^{n} f_i$ has no divisor of degree l.
   (b) $r \geq 1$, $l - r$ odd and $f_{n-s+1} = \cdots = f_n$ with f_n irreducible of degree 2.
   (c) $r = 1$ and $f_{n-s+1} = \cdots = f_n$ with f_n irreducible of degree $k \geq 3$ and $k|l$.
5. [Wim74] Let A_{11}, A_{12}, and a monic polynomial $f \in F[x]$ of degree n be given. Let $h_1|\cdots|h_l$ be the invariant factors of $\left[\, xI_l - A_{11} \mid -A_{12} \,\right]$. Then $p_A(x) = f$ is possible if and only if $h_1 \cdots h_l | f$.
6. All possible invariant polynomials of A are characterized in [Zab87] when A_{11} and A_{12} are given. The statement of this result contains a majorization inequality involving the *controllability indices* of the pair (A_{11}, A_{12}).
7. [Sil87b] Let A_{11}, A_{22}, and n elements $\lambda_1, \ldots, \lambda_n$ of F be given. Assume that $l \geq m$ and let $ip(A_{11}) = g_1|\cdots|g_l$. Then $\sigma(A) = \{\lambda_1, \ldots, \lambda_n\}$ is possible if and only if all the following conditions are satisfied:
   (a) $\operatorname{tr}(A_{11}) + \operatorname{tr}(A_{22}) = \lambda_1 + \cdots + \lambda_n$.
   (b) If $l > m$, then $g_1 \cdots g_{l-m} | (x - \lambda_1) \cdots (x - \lambda_n)$.
   (c) If $A_{11} = aI_l$ and $A_{22} = dI_m$, then there exists a permutation τ of $\{1, \ldots, n\}$ such that $\lambda_{\tau(2i-1)} + \lambda_{\tau(2i)} = a + d$ for $1 \leq i \leq m$ and $\lambda_{\tau(j)} = a$ for $2m + 1 \leq j \leq n$.
8. [Sil87a] Let A_{12}, A_{21}, and n elements $\lambda_1, \ldots, \lambda_n$ of F be given. Then $\sigma(A) = \{\lambda_1, \ldots, \lambda_n\}$ is possible except if, simultaneously, $l = m = 1$, $A_{12} = [\,b\,]$, $A_{21} = [\,c\,]$ and the polynomial $x^2 - (\lambda_1 + \lambda_2)x + bc + \lambda_1\lambda_2 \in F[x]$ is irreducible over F.
9. Let A_{12}, A_{21}, and a monic polynomial $f \in F[x]$ of degree n be given:
   (a) [Fri77] If F is algebraically closed, then $p_A(x) = f$ is always possible.
   (b) [MS00] If $F = \mathbb{R}$ and $n \geq 3$, then $p_A(x) = f$ is possible if and only if either $\min\{\operatorname{rank}(A_{12}), \operatorname{rank}(A_{21})\} > 0$ or f has a divisor of degree l.
   (c) If $F = \mathbb{R}$, $A_{12} = [\,b\,]$, $A_{21} = [\,c\,]$ and $f = x^2 + c_1x + c_2 \in \mathbb{R}[x]$, then $p_A(x) = f$ is possible if and only if $x^2 + c_1x + c_2 + bc$ has a root in $\mathbb{R}$.
10. [Sil91] Let A_{11}, A_{12}, A_{22}, and n elements $\lambda_1, \ldots, \lambda_n$ of F be given. Let $k_1|\cdots|k_l$ be the invariant factors of $\left[\, xI_l - A_{11} \mid -A_{12} \,\right]$, $h_1|\cdots|h_m$ the invariant factors of $\begin{bmatrix} -A_{12} \\ xI_m - A_{22} \end{bmatrix}$, and $g = k_1 \cdots k_l h_1 \cdots h_m$. Then $\sigma(A) = \{\lambda_1, \ldots, \lambda_n\}$ is possible if and only if all the following conditions hold:
    (a) $\operatorname{tr}(A_{11}) + \operatorname{tr}(A_{22}) = \lambda_1 + \cdots + \lambda_n$.

   (b) $g|(x-\lambda_1)\cdots(x-\lambda_n)$.
   (c) If $A_{11}A_{12}+A_{12}A_{22}=\eta A_{12}$ for some $\eta \in F$, then there exists a permutation τ of $\{1,\dots,n\}$ such that $\lambda_{\tau(2i-1)}+\lambda_{\tau(2i)}=\eta$ for $1\leq i\leq t$ where $t=\operatorname{rank}(A_{12})$ and $\lambda_{\tau(2t+1)},\dots,\lambda_{\tau(n)}$ are the roots of g.

11. If a problem of block type is solved for prescribed characteristic polynomial, then the solution for prescribed spectrum easily follows.
12. The book [GKvS95] deals with PEIEPs of block type from an operator point of view.
13. A description is given in [FS98] of all the possible characteristic polynomials of a square matrix with an arbitrary prescribed submatrix.
14. The PEIEPs of 2×2 block type can be generalized to $k\times k$ block matrices with $k\geq 3$. Let
$$A=[A_{ij}]_{i,j=1}^{k}\in F^{n\times n} \quad \text{with } A_{ii}\in F^{m_i\times m_i} \text{ and } m_1\geq\ldots\geq m_k.$$
Let $\lambda_1,\dots,\lambda_n$ be n elements of F and let τ be a permutation of $\{1,\dots,k\}$.
   (a) [CS00] If $m_1=m_k$ and $2n-3$ blocks are prescribed, then $\sigma(A)=\{\lambda_1,\dots,\lambda_n\}$ is possible if and only if the following conditions are satisfied: (1) if $A_{11},\dots,A_{kk}$ are prescribed, then $\sum_{i=1}^{k}\operatorname{tr}(A_{ii})=\sum_{j=1}^{n}\lambda_j$; (2) if $A_{11},\dots,A_{1k}$ are prescribed and $h_1|\cdots|h_{m_1}$ are the invariant factors of $\begin{bmatrix} xI_{m_1}-A_{11} & -A_{12} & \cdots & -A_{1k}\end{bmatrix}$, then $h_1\cdots h_{m_1}|(x-\lambda_1)\cdots(x-\lambda_n)$; (3) if all blocks in any other row or column are prescribed, then the condition is similar to the previous one.
   (b) [CS03] If $A_{1\tau(1)},\dots,A_{k\tau(k)}$ are prescribed, then $\sigma(A)=\{\lambda_1,\dots,\lambda_n\}$ is possible if and only if the following conditions are satisfied: (1) if τ is the identity, then $\sum_{i=1}^{k}\operatorname{tr}(A_{ii})=\sum_{j=1}^{n}\lambda_j$; (2) if $\tau(1)=1$, $m_1>n/2$ and $f_1|\cdots|f_{m_1}$ are the invariant polynomials of A_{11}, then $f_1\cdots f_{2m_1-n}|(x-\lambda_1)\cdots(x-\lambda_n)$.
   (c) [BC12] If F is an integral domain, then the previous result is also valid except for the case $\tau(1)=1$ and $m_1>n/2$ that is not solved. A finite step algorithm provides a solution matrix (if such a matrix exists).
15. A recent survey on the subject can be found in [C09].

28.3 Nonnegative IEP (NIEP)

Nonnegative matrices appear naturally in many different mathematical areas, both pure and applied, such as numerical analysis, statistics, economics, social sciences, etc. One of the most intriguing problems in this field is the so-called *nonnegative IEP* (NIEP). Its origin goes back to A.N. Kolgomorov, who in 1938 posed the problem of determining which individual complex numbers belong to the spectrum of some $n\times n$ nonnegative matrix with its spectral radius normalized to be 1. Kolgomorov's problem was generalized in 1949 by H. R. Suleĭmanova, who posed the NIEP: To determine which n-tuples of complex numbers are spectra of $n\times n$ nonnegative matrices. For definitions and additional facts about nonnegative matrices, see Chapter 10.

Definitions:

Let Π_n denote the compact subset of $\mathbb{C}$ bounded by the regular n-sided polygon inscribed in the unit circle of $\mathbb{C}$ and with one vertex at $1\in\mathbb{C}$.

Let Θ_n denote the subset of $\mathbb{C}$ composed of those complex numbers λ such that λ is an eigenvalue of some $n\times n$ row stochastic matrix.

A **circulant matrix** is a matrix in which every row is obtained by a single cyclic shift of the previous row.

Facts:

All the following facts appear in [Min88].

1. A complex nonzero number λ is an eigenvalue of a nonnegative $n \times n$ matrix with positive spectral radius ρ if and only if $\lambda/\rho \in \Theta_n$.
2. [DD45], [DD46] $\Theta_3 = \Pi_2 \cup \Pi_3$.
3. [Mir63] Each point in $\Pi_2 \cup \Pi_3 \cup \cdots \cup \Pi_n$ is an eigenvalue of a doubly stochastic $n \times n$ matrix.
4. [Kar51] The set Θ_n is symmetric relative to the real axis and is contained within the circle $|z| \leq 1$. It intersects $|z| = 1$ at the points $e^{\frac{2\pi i a}{b}}$ where a and b run over all integers satisfying $0 \leq a < b \leq n$. The boundary of Θ_n consists of the curvilinear arcs connecting these points in circular order. For $n \geq 4$, each arc is given by one of the following parametric equations:

$$\begin{aligned} z^q(z^p - t)^r &= (1-t)^r, \\ (z^c - t)^d &= (1-t)^d z^q, \end{aligned}$$

   where the real parameter t runs over the interval $0 \leq t \leq 1$, and c, d, p, q, r are natural numbers defined by certain rules (explicitly stated in [Min88]).

Examples:

1. [LL78] The circulant matrix

$$\frac{1}{3}\begin{bmatrix} 1+2r\cos\theta & 1-2r\cos(\frac{\pi}{3}+\theta) & 1-2r\cos(\frac{\pi}{3}-\theta) \\ 1-2r\cos(\frac{\pi}{3}-\theta) & 1+2r\cos\theta & 1-2r\cos(\frac{\pi}{3}+\theta) \\ 1-2r\cos(\frac{\pi}{3}+\theta) & 1-2r\cos(\frac{\pi}{3}-\theta) & 1+2r\cos\theta \end{bmatrix}$$

   has spectrum $\{1, re^{i\theta}, re^{-i\theta}\}$, and it is doubly stochastic if and only if $re^{i\theta} \in \Pi_3$.

28.4 Spectra of Nonnegative Matrices

Definitions:

$\mathcal{N}_n \equiv \{\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C} : \exists A \geq 0 \quad \text{with spectrum } \sigma\}$.

$\mathcal{R}_n \equiv \{\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{R} : \exists A \geq 0 \quad \text{with spectrum } \sigma\}$.

$\mathcal{S}_n \equiv \{\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{R} : \exists A \geq 0 \quad \text{symmetric with spectrum } \sigma\}$.

$\mathcal{R}_n^* \equiv \{(1, \lambda_2, \ldots, \lambda_n) \in \mathbb{R}^n : \{1, \lambda_2, \ldots, \lambda_n\} \in \mathcal{R}_n; 1 \geq \lambda_2 \geq \cdots \geq \lambda_n\}$.

$\mathcal{S}_n^* \equiv \{(1, \lambda_2, \ldots, \lambda_n) \in \mathbb{R}^n : \{1, \lambda_2, \ldots, \lambda_n\} \in \mathcal{S}_n; 1 \geq \lambda_2 \geq \cdots \geq \lambda_n\}$.

For any set $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C}$, let

$$\rho(\sigma) = \max_{1 \leq i \leq n} |\lambda_i| \quad \text{and} \quad \mathrm{s}_k = \sum_{i=1}^{n} \lambda_i^k \quad \text{for each } k \in \mathbb{N}.$$

A set $S \subset \mathbb{R}^n$ is **star-shaped** from $p \in S$ if every line segment drawn from p to another point in S lies entirely in S.

Facts:

Most of the following facts appear in [ELN04].

1. [Joh81] If $\sigma = \{\lambda_1, \ldots, \lambda_n\} \in \mathcal{N}_n$, then σ is the spectrum of a $n \times n$ nonnegative matrix with all row sums equal to $\rho(\sigma)$.
2. If $\sigma = \{\lambda_1, \ldots, \lambda_n\} \in \mathcal{N}_n$, then the following conditions hold:

   (a) $\rho(\sigma) \in \sigma$.
   (b) $\overline{\sigma} = \sigma$.
   (c) $\mathrm{s}_i \geq 0$ for $i \geq 1$.
   (d) [LL78], [Joh81] $\mathrm{s}_k^m \leq n^{m-1}\mathrm{s}_{km}$ for $k, m \geq 1$.

3. $\mathcal{N}_n$ is known for $n \leq 3$, $\mathcal{R}_n$ and $\mathcal{S}_n$ are known for $n \leq 4$:
   (a) $\mathcal{N}_2 = \mathcal{R}_2 = \mathcal{S}_2 = \{\sigma = \{\lambda_1, \lambda_2\} \subset \mathbb{R} : \mathrm{s}_1 \geq 0\}$.
   (b) $\mathcal{R}_3 = \mathcal{S}_3 = \{\sigma = \{\lambda_1, \lambda_2, \lambda_3\} \subset \mathbb{R} : \rho(\sigma) \in \sigma;\ \mathrm{s}_1 \geq 0\}$.
   (c) [LL78] $\mathcal{N}_3 = \{\sigma = \{\lambda_1, \lambda_2, \lambda_3\} \subset \mathbb{C} : \overline{\sigma} = \sigma;\ \rho(\sigma) \in \sigma;\ \mathrm{s}_1 \geq 0;\ \mathrm{s}_1^2 \leq 3\mathrm{s}_2\}$.
   (d) $\mathcal{R}_4 = \mathcal{S}_4 = \{\sigma = \{\lambda_1, \lambda_2, \lambda_3, \lambda_4\} \subset \mathbb{R} : \rho(\sigma) \in \sigma;\ \mathrm{s}_1 \geq 0\}$.
4. (a) [JLL96] $\mathcal{R}_n$ and $\mathcal{S}_n$ are not always equal sets.
   (b) [ELN04] $\sigma = \{97, 71, -44, -54, -70\} \in \mathcal{R}_5$ but $\sigma \notin \mathcal{S}_5$.
   (c) [ELN04] provides symmetric matrices for all known elements of $\mathcal{S}_5$.
5. [Rea96] Let $\sigma = \{\lambda_1, \lambda_2, \lambda_3, \lambda_4\} \subset \mathbb{C}$ with $\mathrm{s}_1 = 0$. Then $\sigma \in \mathcal{N}_4$ if and only if $\mathrm{s}_2 \geq 0$, $\mathrm{s}_3 \geq 0$, and $4\mathrm{s}_4 \geq \mathrm{s}_2^2$. Moreover, σ is the spectrum of

$$\begin{bmatrix} 0 & 1 & 0 & 0 \\ \frac{\mathrm{s}_2}{4} & 0 & 1 & 0 \\ \frac{\mathrm{s}_3}{4} & 0 & 0 & 1 \\ \frac{4\mathrm{s}_4 - \mathrm{s}_2^2}{16} & \frac{\mathrm{s}_3}{12} & \frac{\mathrm{s}_2}{4} & 0 \end{bmatrix}.$$

6. [LM99] Let $\sigma = \{\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5\} \subset \mathbb{C}$ with $\mathrm{s}_1 = 0$. Then $\sigma \in \mathcal{N}_5$ if and only if the following conditions are satisfied:
   (a) $\mathrm{s}_i \geq 0$ for $i = 2, 3, 4, 5$.
   (b) $4\mathrm{s}_4 \geq \mathrm{s}_2^2$.
   (c) $12\mathrm{s}_5 - 5\mathrm{s}_2\mathrm{s}_3 + 5\mathrm{s}_3\sqrt{4\mathrm{s}_4 - \mathrm{s}_2^2} \geq 0$.

   The proof of the sufficient part is constructive.
7. (a) $\mathcal{R}_n^*$ and $\mathcal{S}_n^*$ are star-shaped from $(1, \ldots, 1)$.
   (b) [BM97] $\mathcal{R}_n^*$ is star-shaped from $(1, 0, \ldots, 0)$.
   (c) [KM01], [Mou03] $\mathcal{R}_n^*$ and $\mathcal{S}_n^*$ are not convex sets for $n \geq 5$.
8. [TAA07] Given real numbers $k_1, k_2, \ldots, k_n$, find necessary and sufficient conditions for the existence of a nonnegative matrix of order n with characteristic polynomial $x^n + k_1x^{n-1} + \cdots + k_{n-1}x + k_n$. This inverse problem is solved for $n \leq 4$.

Examples:

1. We show that $\sigma = \{5, 5, -3, -3, -3\} \notin \mathcal{N}_5$. Suppose A is a nonnegative matrix with spectrum σ. By the Perron–Frobenius Theorem, A is reducible and σ can be partitioned into two nonempty subsets, each one being the spectrum of a nonnegative matrix with Perron root equal to 5. This is not possible since one of the subsets must contain numbers with negative sum.
2. $\{6, 1, 1, -4, -4\} \in \mathcal{N}_5$ by Fact 6.

28.5 Nonzero Spectra of Nonnegative Matrices

For the definitions and additional facts about primitive matrices see Section 40.6 and Chapter 10.

Definitions:

The **Möbius function** $\mu : \mathbb{N} \mapsto \{-1, 0, 1\}$ is defined by $\mu(1) = 1$, $\mu(m) = (-1)^e$ if m is a product of e distinct primes, and $\mu(m) = 0$ otherwise.

The k^{th} **net trace** of $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C}$ is $\mathrm{tr}_k(\sigma) = \sum_{d|k} \mu(\frac{k}{d})\mathrm{s}_d$.

The set $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C}$ with $0 \notin \sigma$ is the **nonzero spectrum** of a matrix if there exists a $t \times t$ matrix, $t \geq n$, whose spectrum is $\{\lambda_1, \ldots, \lambda_n, 0, \ldots, 0\}$ with $t - n$ zeros.

The set $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C}$ has a **Perron value** if $\rho(\sigma) \in \sigma$ and there exists a unique index i with $\lambda_i = \rho(\sigma)$.

Facts:

1. [BH91] Spectral Conjecture: Let $\mathbb{S}$ be a unital subring of $\mathbb{R}$. The set $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C}$ with $0 \notin \sigma$ is the nonzero spectrum of some primitive matrix over $\mathbb{S}$ if and only if the following conditions hold:
   (a) σ has a Perron value.
   (b) All the coefficients of the polynomial $\prod_{i=1}^{n}(x - \lambda_i)$ lie in $\mathbb{S}$.
   (c) If $\mathbb{S} = \mathbb{Z}$, then $\mathrm{tr}_k(\sigma) \geq 0$ for all positive integers k.
   (d) If $\mathbb{S} \neq \mathbb{Z}$, then $\mathrm{s}_k \geq 0$ for all $k \in \mathbb{N}$ and $\mathrm{s}_m > 0$ implies $\mathrm{s}_{mp} > 0$ for all $m, p \in \mathbb{N}$.
2. [BH91] Subtuple Theorem: Let $\mathbb{S}$ be a unital subring of $\mathbb{R}$. Suppose that $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C}$ with $0 \notin \sigma$ has $\rho(\sigma) = \lambda_1$ and satisfies conditions (a) to (d) of the spectral conjecture. If for some $j \leq n$ the set $\{\lambda_1, \ldots, \lambda_j\}$ is the nonzero spectrum of a nonnegative matrix over $\mathbb{S}$, then σ is the nonzero spectrum of a primitive matrix over $\mathbb{S}$.
3. The spectral conjecture is true for $\mathbb{S} = \mathbb{R}$ by the subtuple theorem.
4. [KOR00] The spectral conjecture is true for $\mathbb{S} = \mathbb{Z}$ and $\mathbb{S} = \mathbb{Q}$.
5. [BH91] The set $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C}$ with $0 \notin \sigma$ is the nonzero spectrum of a positive matrix if and only if the following conditions hold:
   (a) σ has a Perron value.
   (b) All coefficients of $\prod_{i=1}^{n}(x - \lambda_i)$ are real.
   (c) $\mathrm{s}_k > 0$ for all $k \in \mathbb{N}$.

Examples:

1. Let $\sigma_\epsilon = \{5, 4 + \epsilon, -3, -3, -3\}$. Then:
   (a) σ_ϵ for $\epsilon < 0$ is not the nonzero spectrum of a nonnegative matrix since $\mathrm{s}_1 < 0$.
   (b) σ_0 is the nonzero spectrum of a nonnegative matrix by Fact 2.
   (c) σ_1 is not the nonzero spectrum of a nonnegative matrix by arguing as in Example 28.4.1
   (d) σ_ϵ for $\epsilon > 0$, $\epsilon \neq 1$, is the nonzero spectrum of a positive matrix by Fact 5.

28.6 Some Merging Results for Spectra of Nonnegative Matrices

Facts:

1. If $\{\lambda_1, \ldots, \lambda_n\} \in \mathcal{N}_n$ and $\{\mu_1, \ldots, \mu_m\} \in \mathcal{N}_m$, then $\{\lambda_1, \ldots, \lambda_n, \mu_1, \ldots, \mu_m\} \in \mathcal{N}_{n+m}$.

2. [Fie74] Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \in \mathcal{S}_n$ with $\rho(\sigma) = \lambda_1$ and $\tau = \{\mu_1, \ldots, \mu_m\} \in \mathcal{S}_m$ with $\rho(\tau) = \mu_1$. Then $\{\lambda_1 + \epsilon, \lambda_2, \ldots, \lambda_n, \mu_1 - \epsilon, \mu_2, \ldots, \mu_m\} \in \mathcal{S}_{n+m}$ for any $\epsilon \geq 0$ if $\lambda_1 \geq \mu_1$. The proof is constructive.
3. [Šmi04] Let A be a nonnegative matrix with spectrum $\{\lambda_1, \ldots, \lambda_n\}$ and maximal diagonal element d, and let $\tau = \{\mu_1, \ldots, \mu_m\} \in \mathcal{N}_m$ with $\rho(\tau) = \mu_1$. If $d \geq \mu_1$, then $\{\lambda_1, \ldots, \lambda_n, \mu_2, \ldots, \mu_m\} \in \mathcal{N}_{n+m-1}$. The proof is constructive.
4. Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \in \mathcal{N}_n$ with $\rho(\sigma) = \lambda_1$ and let $\epsilon \geq 0$. Then:
   (a) [Wuw97] $\{\lambda_1 + \epsilon, \lambda_2, \ldots, \lambda_n\} \in \mathcal{N}_n$.
   (b) If $\lambda_2 \in \mathbb{R}$, then not always $\{\lambda_1, \lambda_2 + \epsilon, \lambda_3, \ldots, \lambda_n\} \in \mathcal{N}_n$ (see the previous example).
   (c) [Wuw97] If $\lambda_2 \in \mathbb{R}$, then $\{\lambda_1 + \epsilon, \lambda_2 \pm \epsilon, \lambda_3, \ldots, \lambda_n\} \in \mathcal{N}_n$ (the proof is not constructive).

Examples:

1. Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \in \mathcal{N}_n$ with $\rho(\sigma) = \lambda_1$, and $\tau = \{\mu_1, \ldots, \mu_m\} \in \mathcal{N}_m$ with $\rho(\tau) = \mu_1$. By Fact 28.4.1 there exists $A \geq 0$ with spectrum σ and row sums λ_1, and $B \geq 0$ with spectrum τ and row sums μ_1 [BMS04]. If $\lambda_1 \geq \mu_1$ and $\epsilon \geq 0$, then the nonnegative matrix

$$\left[\begin{array}{c|c} A & \epsilon\, \mathbf{e}\mathbf{e}_1^T \\ \hline (\lambda_1 - \mu_1 + \epsilon)\, \mathbf{e}\mathbf{e}_1^T & B \end{array}\right] \geq 0$$

has row sums $\lambda_1 + \epsilon$ and spectrum $\{\lambda_1 + \epsilon, \lambda_2, \ldots, \lambda_n, \mu_1 - \epsilon, \mu_2, \ldots, \mu_m\}$.

28.7 Sufficient Conditions for Spectra of Nonnegative Matrices

Definitions:

The set $\{\lambda_1, \ldots, \lambda_{i-1}, \alpha, \beta, \lambda_{i+1}, \ldots, \lambda_n\}$ is a **negative subdivision** of $\{\lambda_1, \ldots, \lambda_n\}$ if $\alpha + \beta = \lambda_i$ with $\alpha, \beta, \lambda_i < 0$.

The set $\{\lambda_1, \ldots, \lambda_n\}$ is **C-realizable** if it can be reached starting from the n realizable sets $\{0\}$, $\{0\}$, …,$\{0\}$ and successively applying, in any order and any number of times, either Fact 1, Fact 28.6.4(a) or Fact 28.6.4(c).

Facts:

Most of the following facts appear in [ELN04] and [SBM05].

1. [Sul49] Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{R}$ with $\lambda_1 \geq \cdots \geq \lambda_n$. Then $\sigma \in \mathcal{R}_n$ if

$$(\mathbf{Su}) \begin{cases} \bullet\ \lambda_1 \geq 0 \geq \lambda_2 \geq \cdots \geq \lambda_n \\ \bullet\ \lambda_1 + \cdots + \lambda_n \geq 0 \end{cases}.$$

2. [BMS04] Complex version of (Su). Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C}$ be a set that satisfies:
   (a) $\overline{\sigma} = \sigma$.
   (b) $\rho(\sigma) = \lambda_1$.
   (c) $\lambda_1 + \cdots + \lambda_n \geq 0$.
   (d) $\{\lambda_2, \ldots, \lambda_n\} \subset \{z \in \mathbb{C} : \mathrm{Re} z \leq 0, |\mathrm{Re} z| \geq |\mathrm{Im} z|\}$.

   Then $\sigma \in \mathcal{N}_n$ and the proof is constructive.

3. [Sou83] Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{R}$ with $\lambda_1 \geq \cdots \geq \lambda_n$. Then there exists a symmetric doubly stochastic matrix D such that $\lambda_1 D$ has spectrum σ if

$$(\textbf{Sou}) \quad \left\{ \frac{1}{n}\lambda_1 + \frac{n-m-1}{n(m+1)}\lambda_2 + \sum_{k=1}^{m} \frac{\lambda_{n-2k+2}}{(k+1)k} \geq 0 \quad \text{where} \quad m = \left[\tfrac{n-1}{2}\right] \right.$$

and the proof is constructive.

4. [Kel71] Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{R}$ with $\lambda_1 \geq \cdots \geq \lambda_n$. Let r be the greatest index for which $\lambda_r \geq 0$ and let $\delta_i = \lambda_{n+2-i}$ for $2 \leq i \leq n-r+1$. Define $K = \{i : 2 \leq i \leq \min\{r, n-r+1\}$ and $\lambda_i + \delta_i < 0\}$. Then $\sigma \in \mathcal{R}_n$ if

$$(\textbf{Ke}) \quad \begin{cases} \bullet\ \lambda_1 + \sum_{i \in K,\ i<k}(\lambda_i + \delta_i) + \delta_k \geq 0 \text{ for all } k \in K \\ \bullet\ \lambda_1 + \sum_{i \in K}(\lambda_i + \delta_i) + \sum_{j=r+1}^{n-r+1} \delta_j \geq 0 \end{cases}.$$

5. [Bor95] Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{R}$ with $\lambda_1 \geq \cdots \geq \lambda_n$. Then $\sigma \in \mathcal{R}_n$ if

$$(\textbf{Bo}) \quad \begin{cases} \bullet\ \exists\, \tau = \{\beta_1, \ldots, \beta_d\} \subset \mathbb{R} \text{ with } d \leq n \text{ that satisfies conditions (Ke)} \\ \bullet\ \sigma \text{ is obtained from } \tau \text{ after } n-d \text{ negative subdivisions} \end{cases}.$$

6. [Sot03] Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{R}$. For any partition $\sigma = \sigma^{(1)} \cup \cdots \cup \sigma^{(t)}$ where $\sigma^{(k)} = \{\lambda_1^{(k)}, \ldots, \lambda_{n_k}^{(k)}\}$ with $\lambda_1^{(k)} \geq \cdots \geq \lambda_{n_k}^{(k)}$ define

$$\begin{aligned} &R_j^{(k)} = \lambda_j^{(k)} + \lambda_{n_k-j+1}^{(k)} \text{ for } 2 \leq j \leq \left[\tfrac{n_k}{2}\right] \quad \text{and} \quad R_{\frac{n_k+1}{2}}^{(k)} = \lambda_{\frac{n_k+1}{2}}^{(k)} \quad \text{if } n_k \text{ odd;} \\ &T^{(k)} = \lambda_1^{(k)} + \lambda_{n_k}^{(k)} + \textstyle\sum_{R_j^{(k)}<0} R_j^{(k)}. \end{aligned}$$

Then $\sigma \in \mathcal{R}_n$ if

$$(\textbf{Sot}) \quad \begin{cases} \text{there exists a partition } \sigma = \sigma^{(1)} \cup \cdots \cup \sigma^{(t)} \text{ such that} \\ \lambda_1^{(1)} + \displaystyle\sum_{T^{(k)}<0,k=2}^{t} T^{(k)} \geq \max\left\{\lambda_1^{(1)} - T^{(1)}, \max_{2 \leq k \leq t}\{\lambda_1^{(k)}\}\right\} \end{cases}$$

and the proof is constructive.

7. [BMS08] If $\sigma = \{\lambda_1, \ldots, \lambda_n\}$ is C-realizable then $\sigma \in \mathcal{R}_n$.
8. [SBM05], [BMS08] (Su) $\Rightarrow$ (Ke) $\Rightarrow$ (Bo) $\Rightarrow$ (Sot) $\Rightarrow$ C-realizable, and no opposite implication is true.
9. [Rad96] (Sou) and (Ke) are not comparable (see Example 2 next).
10. [Rad96] If σ satisfies (Bo), then $\sigma \in \mathcal{S}_n$.
11. [RS03] Let $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{C}$ with $\overline{\sigma} = \sigma$ and $d = -\sum_{i=2}^{n} \lambda_i > 0$. Let $c_1, \ldots, c_n$ be defined by $(x-d)\prod_{i=2}^{n}(x-\lambda_i) = x^n + \sum_{k=1}^{n} c_k x^{n-k}$. If $\lambda_1 \geq d\big(1 + \sum_{c_k>0} \frac{c_k}{d^k}\big)$, then $\sigma \in \mathcal{N}_n$. The proof is constructive.
12. [MPS07] A map of sufficient conditions for the real nonnegative inverse eigenvalue problem is provided, establishing inclusion or independency relations between them.

Examples:

1. If $\sigma = \{\lambda_1, \ldots, \lambda_n\} \subset \mathbb{R}$ satisfies (Su), then the companion matrix of the polynomial $\prod_{i=1}^{n}(x-\lambda_i)$ is nonnegative with spectrum σ.
2. $\{5, 3, -2, -2, -4\}$ satisfies (Ke), but not (Sou), and $\{5, 3, -2, -2, -2, -2\}$ satisfies (Sou), but not (Ke).
3. $\sigma = \{8, 4, -3, -3, -3, -3\}$ does not satisfies (Ke), but it satisfies (Bo) since σ is obtained from $\tau = \{8, 4, -6, -6\}$ after two negative subdivisions and τ satisfies (Ke).

4. $\sigma = \{9, 7, 2, 2, -5, -5, -5, -5\}$ does not satisfy (Bo), but it satisfies (Sot) with $\sigma^{(1)} = \{9, 2, -5, -5\}$ and $\sigma^{(2)} = \{7, 2, -5, -5\}$.
5. $\sigma = \{6, 1, 1, -4, -4\}$ does not satisfy (Sot), but $\sigma \in \mathcal{R}_5$ (Example 28.4.2).

28.8 Affine Parameterized IEPs (PIEPs)

The set $F^{n\times n}$ of $n \times n$ matrices over the field F is naturally identified with the vector space F^{n^2}. An affine parameterized IEP requires finding within a given affine subspace of $F^{n\times n}$ a matrix with prescribed spectrum. Here we will consider that the given affine subspace is n-dimensional and $F = \mathbb{R}$ or $F = \mathbb{C}$. Especially interesting is the case where the affine subspace contains only real symmetric matrices. Some important motivating applications, including the Sturm–Liouville problem, inverse vibration problems, and nuclear spectroscopy are discussed in [FNO87].

Most of the facts of Sections 28.8, 28.9, and 28.10 appear in [Dai98].

Definitions:

An **affine parameterized IEP** (PIEP) has the following standard formulation:
Given: A field F; $n+1$ matrices $A, A_1, \ldots, A_n \in F^{n\times n}$; and n elements $\lambda_1, \ldots, \lambda_n \in F$.
Find: $\mathbf{c} = (c_1, \ldots, c_n)^T \in F^n$ such that $\{\lambda_1, \ldots, \lambda_n\}$ is the spectrum of the matrix

$$A(\mathbf{c}) = A + c_1 A_1 + \cdots + c_n A_n.$$

In particular, a PIEP($\mathbb{C}$) is a PIEP with $F = \mathbb{C}$, a PIEP($\mathbb{R}$) is a PIEP with $F = \mathbb{R}$, and a PIEP($\mathbb{R}$S) is a PIEP with $F = \mathbb{R}$ and with all given matrices symmetric.

Facts: [Dai98]

1. [Xu92] Almost all PIEP($\mathbb{C}$) are solvable.
2. [SY86] Almost all PIEP($\mathbb{R}$) and almost all PIEP($\mathbb{R}$S) are unsolvable in the presence of multiple eigenvalues.
3. All known sufficient conditions for the solvability of a PIEP($\mathbb{R}$) or a PIEP($\mathbb{R}$S) require that the eigenvalues should be sufficiently pairwise separated. An account of necessary and of sufficient conditions can be found in [Dai98].

28.9 Relevant PIEPs Which Are Solvable Everywhere

Definitions:

Additive IEP (AIEP): Given $A \in \mathbb{C}^{n\times n}$ and $\lambda_1, \ldots, \lambda_n \in \mathbb{C}$, find a diagonal matrix $D \in \mathbb{C}^{n\times n}$ such that $\sigma(A + D) = \{\lambda_1, \ldots, \lambda_n\}$.

Multiplicative IEP (MIEP): Given $B \in \mathbb{C}^{n\times n}$ and $\lambda_1, \ldots, \lambda_n \in \mathbb{C}$, find a diagonal matrix $D \in \mathbb{C}^{n\times n}$ such that $\sigma(BD) = \{\lambda_1, \ldots, \lambda_n\}$.

Toeplitz IEP (ToIEP): Given $\lambda_1, \ldots, \lambda_n \in \mathbb{R}$, find $\mathbf{c} = [c_1, \ldots, c_n]^T \in \mathbb{R}^n$ such that $\left[\, t_{ij} \,\right]_{i,j=1}^{n}$ with $t_{ij} = c_{|i-j|+1}$ has spectrum $\{\lambda_1, \ldots, \lambda_n\}$.

Facts: [Dai98]

1. Each AIEP is a PIEP($\mathbb{C}$) with $A_k = \mathbf{e}_k \mathbf{e}_k^T$ for $k = 1, \ldots, n$. Each AIEP is also an IEP with prescribed (off-diagonal) entries.

2. [Fri77] For any $A \in \mathbb{C}^{n\times n}$ and any $\lambda_1, \dots, \lambda_n \in \mathbb{C}$, the corresponding AIEP is solvable, with the number of solutions not exceeding $n!$. Moreover, for almost all $\lambda_1, \dots, \lambda_n$ there are exactly $n!$ solutions.
3. Each MIEP is a PIEP($\mathbb{C}$) with $A = 0$ and $A_k = \mathbf{v}_k\mathbf{e}_k^T$ for $k = 1, \dots, n$, where $\mathbf{v}_1, \dots, \mathbf{v}_n \in \mathbb{C}^n$ and $B = [\,\mathbf{v}_1 \ \cdots \ \mathbf{v}_n\,] \in \mathbb{C}^{n\times n}$.
4. [Fri75] Assume that all principal minors of $B \in \mathbb{C}^{n\times n}$ are nonzero. For any $\lambda_1, \dots, \lambda_n \in \mathbb{C}$, the corresponding MIEP is solvable, with the number of solutions not exceeding $n!$. Moreover, for almost all $\lambda_1, \dots, \lambda_n$ there are exactly $n!$ solutions.
5. Each ToIEP is a PIEP($\mathbb{RS}$) with $A = 0$ and $A_k = [\,a_{ij}^{(k)}\,]_{i,j=1}^n$, where $a_{ij}^{(k)} = 1$ if $|i-j|+1 = k$ and $a_{ij}^{(k)} = 0$ otherwise.
6. [Lan94] For any $\lambda_1, \dots, \lambda_n \in \mathbb{R}$ the corresponding ToIEP is solvable.

28.10 Numerical Methods for PIEPs

Facts: [Dai98]

1. For a given PIEP($\mathbb{RS}$), it is possible to order both the eigenvalues $\lambda_1 \leq \cdots \leq \lambda_n$ and the eigenvalues $\lambda_1(\mathbf{c}) \leq \cdots \leq \lambda_n(\mathbf{c})$ of $A(\mathbf{c})$. Then solving the PIEP($\mathbb{RS}$) is equivalent to solving the nonlinear system

   $$f(\mathbf{c}) = (\lambda_1(\mathbf{c}) - \lambda_1, \dots, \lambda_n(\mathbf{c}) - \lambda_n)^T = 0.$$

   Assume that a solution $\mathbf{c}^*$ exists and that the given eigenvalues are distinct:

   (a) *Method 1a.* Newton's method provides a locally quadratically convergent (l.q.c.) algorithm, and it is usually l.q.c. even in the presence of multiple eigenvalues [FNO87]. Each iteration in Newton's method involves the solution of an eigenvalue–eigenvector problem.

   (b) *Method 1b.* A Newton-like method is given in [FNO87] . Newton's method is modified by using the inverse power method to find approximate eigenvectors in each iteration. The new algorithm maintains l.q.c. (see [CXZ99]).

   (c) *Method 1c.* An inexact Newton-like method is given in [CCX03] . The last iterations of the inverse power method are truncated avoiding oversolving. The algorithm converges superlinearly, but the overall cost is reduced. In particular, for ToIEPs, this improved algorithm has better performance than specific known algorithms.
2. For a given PIEP($\mathbb{R}$) or PIEP($\mathbb{C}$), complex eigenvalues can appear. Assume that for the corresponding PIEP a solution $\mathbf{c}^*$ exists:

   (a) *Method 2.* In [BK81], Newton's method is applied to solve

   $$f(\mathbf{c}) = (\det(A(\mathbf{c}) - \lambda_1 I_n), \dots, \det(A(\mathbf{c}) - \lambda_n I_n))^T = 0.$$

   The algorithm is l.q.c. and is suitable for the case of distinct eigenvalues.

   (b) *Method 3.* Newton's method is applied in [Xu96] to solve

   $$f(\mathbf{c}) = (\sigma_{min}(A(\mathbf{c}) - \lambda_1 I_n), \dots, \sigma_{min}(A(\mathbf{c}) - \lambda_n I_n))^T = 0,$$

   where σ_{min} denotes the smallest singular value. The algorithm is l.q.c. under mild conditions even when multiple eigenvalues are present.

   (c) *Method 4a.* An l.q.c. algorithm based on the QR decomposition theory is given in [Li92] that is suitable for the case of distinct eigenvalues.

   (d) *Method 4b.* Method 4a is extended in [Dai99] to the case of multiple eigenvalues for any PIEP(ℝS). The new algorithm is l.q.c. and is based on QR-like decomposition theory and least square techniques. Methods 4a and 4b are given in a more general context.

3. All previous methods require starting from an initial point close to a solution in order to guarantee convergence.

   (a) *Method 5.* A homotopy approach has been considered for complex symmetric matrices (see [Chu90], [Xu93]), which in theory provides a globally convergent algorithm by which all solutions can be found.

Total positivity has been a recurring theme in linear algebra and other aspects of mathematics for the past 80 years. Totally positive matrices, in fact, originated from studying small oscillations in mechanical systems [GK60], and from investigating relationships between the number of sign changes of the vectors $\mathbf{x}$ and $A\mathbf{x}$ for fixed A [Sch30]. Since then this class (and the more general class of sign-regular matrices) has arisen in such a wide range of applications (see [GM96] for an incredible compilation of interesting articles dealing with a long list of relevant applications of totally nonnegative matrices) that, over the years, many convenient points of view for total positivity have been offered and later defended by a number of prominent mathematicians.

After F.R. Gantmacher and M.G. Krein [GK60], totally positive matrices were seen and further developed in connection with spline functions, collocation matrices, and generating totally positive sequences (or Polya frequency sequences). Then in 1968 came one of the most important and influential references in this area, namely the book *Total Positivity* by S. Karlin [Kar68]. Karlin approached total positivity by considering the analytic properties of totally positive functions. Along these lines, he studied totally positive kernels, sign-regular functions, and Polya frequency functions. Karlin also noted the importance of total positivity in the fields of probability and statistics.

The next significant viewpoint came from T. Ando's survey paper [And87]. Ando's contribution was to consider a multilinear approach to this subject, namely making use of skew-symmetric products and Schur complements as his underlying tools. More recently, it has become more apparent that factorizations of totally positive matrices are a fruitful avenue for further research on this class. Coupled with matrix factorizations, totally positive matrices have taken on a new combinatorial form known as Planar networks. Karlin and G. McGregor [KM59] were some of the pioneers of this view point on total positivity (see also [Bre95] or [Lin73]), and there has since been a revolution of sorts with many new and exciting advances and additional applications (e.g., positive elements in reductive Lie groups, computer-aided geometric design, shape-preserving designs).

This area is not only a historically significant one in linear algebra, but continues to produce many important advances and spawn many more worthwhile applications. In fact, over the past two years, two new books ([FJ11] and [Pin10]) on this topic have appeared adding additional excitement and interest to this useful and important research area.

29.1 Basic Properties

In this section, we present many basic, yet fundamental, properties associated with the important class of totally positive and totally nonnegative matrices.

Definitions:

An $m \times n$ real matrix A is **totally nonnegative** (TN) if the determinant of every square submatrix (i.e., minor) of A is nonnegative.

An $m \times n$ real matrix A is **totally positive** (TP) if every minor of A is positive.

An $n \times n$ matrix A is **oscillatory** if A is totally nonnegative and A^k is totally positive for some integer $k \geq 1$.

An $m \times n$ real matrix A is TP_k if all minors of A up to order k are positive.

An $m \times n$ real matrix A is TN_k if all minors of A up to order k are nonnegative.

An $m \times n$ real matrix is **in double echelon form** if

(a) Each row of A has one of the following forms ($*$ indicates a nonzero entry):

1. $(*, *, \cdots, *)$,
2. $(*, \cdots, *, 0, \cdots, 0)$,
3. $(0, \cdots, 0, *, \cdots, *)$, or
4. $(0, \cdots, 0, *, \cdots, *, 0, \cdots, 0)$.

(b) The first and last nonzero entries in row $i+1$ are not to the left of the first and last nonzero entries in row i, respectively ($i = 1, 2, \ldots, n-1$).

Facts:

1. Every totally positive matrix is a totally nonnegative matrix.
2. Suppose A is a totally nonnegative (positive) rectangular matrix. Then
   (a) A^T, the transpose of A, is totally nonnegative (positive),
   (b) $A[\alpha, \beta]$ is totally nonnegative (positive) for any row index set α and column index set β.
3. (Section 4.2) Cauchy–Binet Identity: Since any $k \times k$ minor of the product AB is a sum of products of $k \times k$ minors of A and B, it follows that if all the $k \times k$ minors of two $n \times n$ matrices are nonnegative (positive), then all the $k \times k$ minors of their product are nonnegative (positive).
4. [GK02, p. 74], [And87] The set of all totally nonnegative (positive) matrices is closed under conventional multiplication.
5. Let A be TP (TN) and D_1 and D_2 be two positive diagonal matrices. Then $D_1 A D_2$ is TP (TN).
6. [And87], [Fal01], [Whi52], [Kar68, p. 98] The closure of the totally positive matrices (in the usual topology on $\mathbb{R}^{m \times n}$) is the totally nonnegative matrices.
7. Facts 2 through 6 can be extended accordingly to the class of TN_k matrices.
8. [GK02, p. 75] If A is a square invertible totally nonnegative (or is totally positive) matrix, then $SA^{-1}S$ is totally nonnegative (positive) for $S = \mathrm{diag}(1, -1, \cdots, \pm 1)$. Hence, if A is a square invertible totally nonnegative matrix (or is totally positive), then the unsigned adjugate matrix of A (or the $(n-1)$st compound of A) is totally nonnegative (positive).
9. [And87], [Fal99] If A is a square totally nonnegative (positive) matrix, then, assuming $A[\alpha^c]$ is invertible, $A/A[\alpha^c] = A[\alpha] - A[\alpha, \alpha^c](A[\alpha^c])^{-1} A[\alpha^c, \alpha]$, the Schur complement

of $A[\alpha^c]$ in A, is totally nonnegative (positive), for all index sets α based on consecutive indices. Recall that α^c denotes the complement of the set α.

10. [Fal99], [JS00] Let $A = [\mathbf{a_1}, \mathbf{a_2}, \ldots, \mathbf{a_n}]$ be an $m \times n$ totally nonnegative (positive) matrix whose i^{th} column is $\mathbf{a_i}$ $(i = 1, 2, \ldots, n)$. Suppose C denotes the set of all column vectors $\mathbf{b}$ for which the $m \times (n+1)$ matrix $\hat{A} = [\mathbf{a_1}, \ldots, \mathbf{a_k}, \mathbf{b}, \mathbf{a_{k+1}}, \ldots, \mathbf{a_n}]$ is a totally nonnegative (positive) matrix (here k is fixed but arbitrary). Then C is a nonempty convex cone.
11. [Fal99] If A is an $m \times n$ totally nonnegative (positive) matrix, then increasing the (1,1) or the (m, n) entries of A results in a totally nonnegative (positive) matrix. In general, these are the only two entries in a TN matrix with this property (see [FJS00]).
12. [And87] Let P denote the $n \times n$ permutation matrix induced by the permutation $i \to n - i + 1$, $(1 \leq i \leq n)$, and suppose A is an $n \times n$ totally nonnegative (positive) matrix. Then PAP is a totally nonnegative (positive) matrix.
13. [Fal99] Let A be an $m \times n$ totally nonnegative matrix with no zero rows or columns. Then A must be in double echelon form.
14. [Rad68], [Fal99] An $n \times n$ totally nonnegative matrix $A = [a_{ij}]$ is irreducible if and only if $a_{i,i+1} > 0$ and $a_{i+1,i} > 0$, for $i = 1, 2, \ldots, n-1$.
15. [Fal99], [BK10] The totally nonnegative (0,1) matrices have been completely characterized.

Examples:

1. Consider the following 3×3 matrix: $A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 2 & 4 \\ 1 & 3 & 9 \end{bmatrix}$. It is not difficult to check that all minors of A are positive. Hence, A is TP.
2. (Inverse tridiagonal matrix) From Fact 8, the inverse of a TN tridiagonal matrix is signature similar to a TN matrix. Such matrices are referred to as "single-pair" matrices in [GK02, pp. 78–80], are very much related to "Green's matrices" (see [Kar68, pp. 110–112]), and are connected with matrices of type D found in [Mar70a].
3. The matrix
$$[\min\{i,j\}] = \begin{bmatrix} 1 & 1 & 1 & \cdots & 1 \\ 1 & 2 & 2 & \cdots & 2 \\ 1 & 2 & 3 & \cdots & 3 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 2 & 3 & \cdots & n \end{bmatrix}$$
is the inverse of a tridiagonal matrix and is also an invertible TN matrix.
4. (Vandermonde matrix) Square Vandermonde matrices arise in the problem of determining a polynomial of degree at most $n-1$ that interpolates n data points. Suppose that n data points $(x_i, y_i)_{i=1}^n$ are given. The goal is to construct a polynomial $p(x) = a_0 + a_1 x + \cdots + a_{n-1} x^{n-1}$ that satisfies $p(x_i) = y_i$ for $i = 1, 2, \ldots, n$, which can be expressed as
$$\begin{bmatrix} 1 & x_1 & x_1^2 & \cdots & x_1^{n-1} \\ 1 & x_2 & x_2^2 & \cdots & x_2^{n-1} \\ \vdots & & \vdots & & \vdots \\ 1 & x_n & x_n^2 & \cdots & x_n^{n-1} \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_{n-1} \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}. \tag{29.1}$$
The $n \times n$ coefficient matrix in Eq. (29.1) is called a *Vandermonde matrix*, and we denote it by $\mathcal{V}(x_1, \ldots, x_n)$. The determinant of the $n \times n$ Vandermonde matrix in Eq. (29.1) is

given by the formula $\prod_{i>j}(x_i - x_j)$; see [MM64, pp. 15–16]. Thus, if $0 < x_1 < x_2 < \cdots < x_n$, then $\mathcal{V}(x_1, \ldots, x_n)$ has positive entries, positive leading principal minors, and positive determinant. More generally, it is known [GK02, p. 111] that if $0 < x_1 < x_2 < \cdots < x_n$, then $\mathcal{V}(x_1, \ldots, x_n)$ is TP. The matrix A in Example 1 is a Vandermonde matrix.

5. Let $f(x) = \sum_{i=0}^{n} a_i x^i$ be an n^{th} degree polynomial in x. The *Routh–Hurwitz matrix* is the $n \times n$ matrix given by

$$A = \begin{bmatrix} a_1 & a_3 & a_5 & a_7 & \cdots & 0 & 0 \\ a_0 & a_2 & a_4 & a_6 & \cdots & 0 & 0 \\ 0 & a_1 & a_3 & a_5 & \cdots & 0 & 0 \\ 0 & a_0 & a_2 & a_4 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \cdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & a_{n-1} & 0 \\ 0 & 0 & 0 & 0 & \cdots & a_{n-2} & a_n \end{bmatrix}.$$

A specific example of a Routh–Hurwitz matrix for an arbitrary polynomial of degree six, $f(x) = \sum_{i=0}^{6} a_i x^i$, is given by

$$A = \begin{bmatrix} a_1 & a_3 & a_5 & 0 & 0 & 0 \\ a_0 & a_2 & a_4 & a_6 & 0 & 0 \\ 0 & a_1 & a_3 & a_5 & 0 & 0 \\ 0 & a_0 & a_2 & a_4 & a_6 & 0 \\ 0 & 0 & a_1 & a_3 & a_5 & 0 \\ 0 & 0 & a_0 & a_2 & a_4 & a_6 \end{bmatrix}.$$

A polynomial $f(x)$ is *stable* if all the zeros of $f(x)$ have negative real parts. It is proved in [Asn70] that $f(x)$ is stable if and only if the Routh–Hurwitz matrix formed from f is invertible and totally nonnegative.

6. (Cauchy matrix) An $n \times n$ matrix $C = [c_{ij}]$ is called a *Cauchy matrix* if the entries of C are given by

$$c_{ij} = \frac{1}{x_i - y_j},$$

where $x_1, x_2, \ldots, x_n$ and $y_1, y_2, \ldots, y_n$ are two sequences of real numbers (chosen so that c_{ij} is well defined). A Cauchy matrix is totally positive if and only if $0 < x_1 < x_2 < \cdots < x_n$ and $y_n < y_{n-1} < \cdots < y_1 < 0$ [GK02, pp. 77–78].

7. (Pascal matrix) Consider the 4×4 matrix $P_4 = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{bmatrix}$. The matrix P_4 is called the *symmetric* 4×4 *Pascal matrix* because of its connection with Pascal's triangle (see Example 29.2.4 for a definition of P_n for general n). Then P_4 is TP, and the inverse of P_4 is given by

$$P_4^{-1} = \begin{bmatrix} 4 & -6 & 4 & -1 \\ -6 & 14 & -11 & 3 \\ 4 & -11 & 10 & -3 \\ -1 & 3 & -3 & 1 \end{bmatrix}.$$

Notice that the inverse of the 4×4 Pascal matrix is integral. Moreover, deleting the signs by forming $SP_4^{-1}S$, where $S = \mathrm{diag}(1, -1, 1, -1)$, results in the TP matrix $\begin{bmatrix} 4 & 6 & 4 & 1 \\ 6 & 14 & 11 & 3 \\ 4 & 11 & 10 & 3 \\ 1 & 3 & 3 & 1 \end{bmatrix}$.

Applications:

1. (Tridiagonal matrices) When Gantmacher and Krein were studying the oscillatory properties of an elastic segmental continuum (no supports between the endpoints a and b) under small transverse oscillations, they generated a system of linear equations that defined the frequencies of the oscillations (see [GK60]). The system of equations thus found can be represented in what is known as the influence-coefficient matrix, whose properties are analogous to those governing the segmental continuum. This process of obtaining the properties of the segmental continuum from the influence-coefficient matrix was only possible due to the inception of the theory of oscillatory matrices. A special case involves tridiagonal matrices (or Jacobi matrices as they were called in [GK02]). Tridiagonal matrices are not only interesting in their own right as a model example of oscillatory matrices, but they also naturally arise in studying small oscillations in certain mechanical systems, such as torsional oscillations of a system of disks fastened to a shaft. In [GK02, pp. 81–82] they proved that an irreducible tridiagonal matrix is totally nonnegative if and only if its entries are nonnegative and its leading principal minors are nonnegative.
2. A real function (or kernel) $k(x, y)$ in two variables, along with two linearly ordered sets X, Y is said to be *totally positive of order* n if for every

   $$x_1 < x_2 < \cdots < x_n;\;\; y_1 < y_2 < \cdots < y_n,\;\; x_i \in X,\;\; y_j \in Y,$$

   we have

   $$\det \begin{bmatrix} k(x_1, y_1) & \cdots & k(x_1, y_n) \\ \vdots & \ddots & \vdots \\ k(x_n, y_1) & \cdots & k(x_n, y_n) \end{bmatrix} > 0.$$

   The term *totally nonnegative for a function* $k(x, y)$ is used if the inequalities above are not necessarily strict.

   We issue a word of warning here: In the existing literature, the terminology used is not always consistent with what is presented above. Sometimes the term totally positive above corresponds to strictly totally positive and totally nonnegative corresponds to totally positive.

   There are many examples of totally positive functions. For instance,

   (1) $k(x, y) = e^{xy}$ (see [Kar68, p. 15]), $x, y \in (-\infty, \infty)$,

   (2) $k(x, y) = x^y$, $x \in (0, \infty)$, $y \in (-\infty, \infty)$

   are both (over their respective domains) totally positive functions.

   Observe that for a fixed n and given $0 < x_1 < x_2 < \cdots < x_n$ and $y_1 < y_2 < \cdots < y_n$, the $n \times n$ matrix $(k(x_i, y_j))_{i,j=1}$ is a generalized Vandermonde matrix, when $k(x, y) = x^y$. For instance, if $n = 4$, then the matrix in question is given by

   $$\begin{bmatrix} x_1^{y_1} & x_1^{y_2} & x_1^{y_3} & x_1^{y_4} \\ x_2^{y_1} & x_2^{y_2} & x_2^{y_3} & x_2^{y_4} \\ x_3^{y_1} & x_3^{y_2} & x_3^{y_3} & x_3^{y_4} \\ x_4^{y_1} & x_4^{y_2} & x_4^{y_3} & x_4^{y_4} \end{bmatrix}.$$

   An important example is when a totally positive function of order n, say $k(x, y)$, can be written as $k(x, y) = f(x - y)$ $(x, y \in \mathbb{R})$. In this case, the function $f(u)$ is called a *Pólya frequency function of order* n, and is often abbreviated as PF_n (see [Kar68], for example). Further, if $k(x, y) = f(x - y)$ but $x, y \in \mathbb{Z}$, then $f(u)$ is said to be a *Pólya frequency sequence of order* n.

29.2 Factorizations

Recently, there has been renewed interest in total positivity partly motivated by the so-called "bidiagonal factorization," namely, the fact that any totally positive matrix can be factored into entry-wise nonnegative bidiagonal matrices. This result has proven to be a very useful and tremendously powerful property for this class. (See Section 1.6 for basic information on LU factorizations.)

Definitions:

An **elementary bidiagonal matrix** is an $n \times n$ matrix whose main diagonal entries are all equal to one, and there is, at most, one nonzero off-diagonal entry and this entry must occur on the super- or subdiagonal. The lower elementary bidiagonal matrix whose elements are given by

$$c_{ij} = \begin{cases} 1, & \text{if } i = j, \\ \mu, & \text{if } i = k,\ j = k-1, \\ 0, & \text{otherwise,} \end{cases}$$

is denoted by $E_k(\mu) = [c_{ij}]$ $(2 \leq k \leq n)$.

A triangular matrix is **ΔTP** if all of its nontrivial minors are positive. (Here a trivial minor is one that is necessarily zero only because of the zero pattern of a triangular matrix.)

Facts:

1. $(E_k(\mu))^{-1} = E_k(-\mu)$.
2. [Cry73] Let A be an $n \times n$ matrix. Then A is totally positive if and only if A has an LU factorization such that both L and U are $n \times n$ ΔTP matrices.
3. [And87], [Cry76] Let A be an $n \times n$ matrix. Then A is totally nonnegative if and only if A has an LU factorization such that both L and U are $n \times n$ totally nonnegative matrices.
4. [Whi52] Suppose $A = [a_{ij}]$ is an $n \times n$ matrix with $a_{j1}, a_{j+1,1} > 0$, and $a_{k1} = 0$ for $k > j+1$. Let B be the $n \times n$ matrix obtained from A by using row j to eliminate $a_{j+1,1}$. Then A is TN if and only if B is TN. Note that B is equal to $E_{j+1}(-a_{j+1,1}/a_{j1})A$ and, hence, $A = (E_{j+1}(-a_{j+1,1}/a_{j1}))^{-1}B = E_{j+1}(a_{j+1,1}/a_{j1})B$.
5. [Loe55], [GP96], [BFZ96], [FZ00], [Fal01], [FJ11] Let A be an $n \times n$ nonsingular totally nonnegative (TP) matrix. Then A can be written as

$$\begin{aligned} A = {} & (E_2(l_k))(E_3(l_{k-1})E_2(l_{k-2})) \cdots (E_n(l_{n-1}) \cdots E_3(l_2)E_2(l_1))D \\ & (E_2^T(u_1)E_3^T(u_2) \cdots E_n^T(u_{n-1})) \cdots (E_2^T(u_{k-2})E_3^T(u_{k-1}))(E_2^T(u_k)), \end{aligned} \tag{29.2}$$

   where $k = \binom{n}{2}$; $l_i, u_j \geq 0$ $(l_i, u_j > 0)$ for all $i, j \in \{1, 2, \ldots, k\}$; and D is a positive diagonal matrix.
6. [Cry76] Any $n \times n$ totally nonnegative matrix A can be written as

$$A = \prod_{i=1}^{M} L^{(i)} \prod_{j=1}^{N} U^{(j)}, \tag{29.3}$$

   where the matrices $L^{(i)}$ and $U^{(j)}$ are, respectively, lower and upper bidiagonal totally nonnegative matrices with at most one nonzero entry off the main diagonal.
7. [Cry76], [RH72] If A is an $n \times n$ totally nonnegative matrix, then there exists a totally nonnegative matrix S and a tridiagonal totally nonnegative matrix T such that
   (a) $TS = SA$.
   (b) The matrices A and T have the same eigenvalues.

Moreover, if A is nonsingular, then S is nonsingular.

8. [BFZ96], [Bre95], [Fal01], [Fal04], [FZ00], [FJ11] Bidiagonal factorizations in general have an important combinatorial interpretation (via planar networks) that has lead to numerous connections between total positivity and combinatorics.

Examples:

1. Let P_4 be the matrix given in Example 29.1.7. Then P_4 is TP, and a (unique up to a positive diagonal scaling) LU factorization of P_4 is given by

$$P_4 = LU = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 2 & 1 & 0 \\ 1 & 3 & 3 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 \\ 0 & 0 & 1 & 3 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

Observe that the rows of L, or the columns of U, come from the rows of Pascal's triangle (ignoring the zeros); hence, the name Pascal matrix (see Example 4 for a definition of P_n).

2. The 3×3 Vandermonde matrix A in Example 29.1.1 can be factored as

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{bmatrix}$$
$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}. \tag{29.4}$$

3. In fact, we can write $\mathcal{V}\ (x_1, x_2, x_3)$ as

$$\mathcal{V}(x_1, x_2, x_3) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & \frac{(x_3-x_2)}{(x_2-x_1)} & 1 \end{bmatrix}$$
$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & x_2 - x_1 & 0 \\ 0 & 0 & (x_3 - x_2)(x_3 - x_1) \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & x_2 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & x_1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & x_1 \\ 0 & 0 & 1 \end{bmatrix}.$$

4. Consider the factorization (29.2) from Fact 5 of a 4×4 matrix in which all of the variables are equal to one. The resulting matrix is P_4, which is necessarily TP. On the other hand, consider the $n \times n$ matrix $P_n = [p_{ij}]$ whose first row and column entries are all ones, and for $2 \leq i, j \leq n$ let $p_{ij} = p_{i-1,j} + p_{i,j-1}$. In fact, the relation $p_{ij} = p_{i-1,j} + p_{i,j-1}$ implies [Fal01] that P_n can be written as

$$P_n = E_n(1) \cdots E_2(1) \begin{bmatrix} 1 & 0 \\ 0 & P_{n-1} \end{bmatrix} E_2^T(1) \cdots E_n^T(1).$$

Hence, by induction, P_n has the factorization (29.2) in which the variables involved are all equal to one. Consequently, the symmetric Pascal matrix P_n is TP for all $n \geq 1$. Furthermore, since in general $(E_k(\mu))^{-1} = E_k(-\mu)$ (Fact 1), it follows that P_n^{-1} is not only signature similar to a TP matrix, but it is also integral.

29.3 Recognition and Testing

In practice, how can one determine if a given $n \times n$ matrix is TN or TP? One could calculate *every* minor, but that would involve evaluating $\sum_{k=1}^{n} \binom{n}{k}^2 \sim 4^n/\sqrt{\pi n}$ determinants. Is there a smaller collection of minors whose nonnegativity or positivity implies the nonnegativity or positivity of all minors?

Definitions:

For $\alpha = \{i_1, i_2, \ldots, i_k\} \subseteq N = \{1, 2, \ldots, n\}$, with $i_1 < i_2 < \cdots < i_k$, the **dispersion of** α, denoted by $d(\alpha)$, is defined to be $\sum_{j=1}^{k-1}(i_{j+1} - i_j - 1) = i_k - i_1 - (k-1)$, with the convention that $d(\alpha) = 0$, when α is a singleton.

If α and β are two contiguous index sets with $|\alpha| = |\beta| = k$, then the minor $\det A[\alpha, \beta]$ is called **initial** if α or β is $\{1, 2, \ldots, k\}$. A minor is called a **leading principal minor** if it is an initial minor with both $\alpha = \beta = \{1, 2, \ldots, k\}$.

An upper right (lower left) **corner minor** of A is one of the form $\det A[\alpha, \beta]$ in which α consists of the first k (last k) and β consists of the last k (first k) indices, $k = 1, 2, \ldots, n$.

Facts:

1. The dispersion of a set α represents a measure of the "gaps" in the set α. In particular, observe that $d(\alpha) = 0$ if and only if α is a contiguous subset of N.
2. [Fek13] (Fekete's Criterion) An $m \times n$ matrix A is totally positive if and only if $\det A[\alpha, \beta] > 0$, for all $\alpha \subseteq \{1, 2, \ldots, m\}$ and $\beta \subseteq \{1, 2, \ldots, n\}$, with $|\alpha| = |\beta|$ and $d(\alpha) = d(\beta) = 0$. (Reduces the number of minors to be checked for total positivity to roughly n^3.)
3. [GP96], [FZ00] If all initial minors of A are positive, then A is TP. (Reduces the number of minors to be checked for total positivity to n^2.)
4. [SS95], [Fal04] Suppose that A is TN. Then A is TP if and only if all corner minors of A are positive.
5. [GP96] Let $A \in \mathbb{R}^{n \times n}$ be nonsingular.
   (a) A is TN if and only if for each $k = 1, 2, \ldots, n$,
      i. $\det A[\{1, 2, \ldots, k\}] > 0$.
      ii. $\det A[\alpha, \{1, 2, \ldots, k\}] \geq 0$, for every $\alpha \subseteq \{1, 2, \ldots, n\}$, $|\alpha| = k$.
      iii. $\det A[\{1, 2, \ldots, k\}, \beta] \geq 0$, for every $\beta \subseteq \{1, 2, \ldots, n\}$, $|\beta| = k$.
   (b) A is TP if and only if for each $k = 1, 2 \ldots, n$,
      i. $\det A[\alpha, \{1, 2, \ldots, k\}] > 0$, for every $\alpha \subseteq \{1, 2, \ldots, n\}$ with $|\alpha| = k$, $d(\alpha) = 0$.
      ii. $\det A[\{1, 2, \ldots, k\}, \beta] > 0$, for every $\beta \subseteq \{1, 2, \ldots, n\}$ with $|\beta| = k$, $d(\beta) = 0$.
6. [GK02, p. 100] An $n \times n$ totally nonnegative matrix $A = [a_{ij}]$ is oscillatory if and only if
   (a) A is nonsingular.
   (b) $a_{i,i+1} > 0$ and $a_{i+1,i} > 0$, for $i = 1, 2, \ldots, n-1$.
7. [Fal04] Suppose A is an $n \times n$ invertible totally nonnegative matrix. Then A is oscillatory if and only if a parameter from at least one of the bidiagonal factors E_k and E_k^T is positive, for each $k = 2, 3, \ldots, n$ in the elementary bidiagonal factorization of A given in Fact 29.2.5.

Examples:

1. Unfortunately, Fekete's Criterion, Fact 2 above, does not hold in general if "totally positive" is replacedwith "totally nonnegative" and "> 0" is replaced with "≥ 0." Consider the following simple example: $A = \begin{bmatrix} 1 & 0 & 2 \\ 1 & 0 & 1 \\ 2 & 0 & 1 \end{bmatrix}$. It is not difficult to verify that every minor of A based on contiguous row and column sets is nonnegative, but $\det A[\{1,3\}] = -3$. For an invertible and irreducible example consider $A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$.

29.4 Spectral Properties

Approximately 60 years ago, Gantmacher and Krein [GK60], who were originally interested in oscillation dynamics, undertook a careful study into the theory of totally nonnegative matrices. Of the many topics they considered, one was the properties of the eigenvalues of totally nonnegative matrices.

Facts:

1. [GK02, pp. 86–91] Let A be an $n \times n$ oscillatory matrix. Then the eigenvalues of A are positive, real, and distinct. Moreover, an eigenvector $\mathbf{x_k}$ corresponding to the k^{th} largest eigenvalue has exactly $k-1$ variations in sign for $k = 1, 2, \ldots, n$. Furthermore, assuming we choose the first entry of each eigenvector to be positive, the positions of the sign change in each successive eigenvectors interlace. (See Preliminaries for the definition of interlace.)
2. [And87] Let A be an $n \times n$ totally nonnegative matrix. Then the eigenvalues of A are real and nonnegative.
3. [FGJ00] Let A be an $n \times n$ irreducible totally nonnegative matrix. Then the positive eigenvalues of A are distinct.
4. [GK02, pp. 107–108] If A is an $n \times n$ oscillatory matrix, then the eigenvalues of A are distinct and strictly interlace the eigenvalues of the two principal submatrices of order $n-1$ obtained from A by deleting the first row and column or the last row and column. If A is an $n \times n$ TN matrix, then non-strict interlacing holds between the eigenvalues of A and the two principal submatrices of order $n-1$ obtained from A by deleting the first row and column or the last row and column.
5. [Pin98] If A is an $n \times n$ totally positive matrix with eigenvalues $\lambda_1 > \lambda_2 > \cdots > \lambda_n$ and $A(k)$ is the $(n-1) \times (n-1)$ principal submatrix obtained from A by deleting the kth row and column with eigenvalues $\mu_1 > \mu_2 > \cdots > \mu_{n-1}$, then for $j = 1, 2, \ldots, n-1$, $\lambda_{j-1} > \mu_j > \lambda_{j+1}$, where $\lambda_0 = \lambda_1$. In the usual Cauchy interlacing inequalities [MM64, p. 119] for positive semidefinite matrices, λ_{j-1} is replaced by λ_j. The strict inequalities need not hold for TN matrices. The extreme cases $(j = 1, n-1)$ of this interlacing result were previously proved in [Fri85].
6. [Gar82] Let $n \geq 2$ and $A = [a_{ij}]$ be an oscillatory matrix. Then the main diagonal entries of A are majorized by the eigenvalues of A. (See Preliminaries for the definition of majorization.)
7. [FG05] Let A be an irreducible $n \times n$ TN matrix. Then

(1) A has at least one non-zero eigenvalue. Furthermore, the non-zero eigenvalues of A are positive and distinct.

(2) Let p be the number of non-zero (or positive) eigenvalues of A. For each $i \geq 1$, let $m_i = m_i(A)$ denote the number of Jordan blocks of size i corresponding to the zero eigenvalue in the Jordan canonical form of A. Then the numbers m_i satisfy the following conditions:

(a) $\sum im_i = n - p$.

(b) $m_i = 0$ for $i > p$.

(c) $\sum m_i \geq \frac{n-p}{p}$.

(3) Conversely, let $n \geq 2$, let $1 \leq p \leq n$, let $\lambda_1, \ldots, \lambda_p$ be arbitrary distinct positive numbers and let $m_1, m_2, \ldots$ be nonnegative integers satisfying the conditions in 2.

Then there exists an irreducible TN matrix A having non-zero eigenvalues $\lambda_1, \ldots, \lambda_p$ and with $m_i(A) = m_i$ for all $i \geq 1$.

Examples:

1. Consider the 4×4 TP matrix $P_4 = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{bmatrix}$. Then the eigenvalues of P_4 are 26.305, 2.203, .454, and .038, with respective eigenvectors

$$\begin{bmatrix} .06 \\ .201 \\ .458 \\ .864 \end{bmatrix}, \begin{bmatrix} .53 \\ .64 \\ .392 \\ -.394 \end{bmatrix}, \begin{bmatrix} .787 \\ -.163 \\ -.532 \\ .265 \end{bmatrix}, \begin{bmatrix} .309 \\ -.723 \\ .595 \\ -.168 \end{bmatrix}.$$

2. The irreducible, singular TN (Hessenberg) matrix given by $H = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix}$ has eigenvalues equal to 3, 1, 0, 0. Notice the positive eigenvalues of H are distinct.
3. Using the TP matrix P_4 in Example 1, the eigenvalues of $P_4(\{1\})$ are 26.213, 1.697, and .09. Observe that the usual Cauchy interlacing inequalities are (strictly) satisfied in this case.

29.5 Deeper Properties

In this section, we explore more advanced topics that are not only interesting in their own right, but also continue to demonstrate the delicate structure and beauty of these matrices.

Definitions:

For a given vector $\mathbf{c} = (c_1, c_2, \ldots, c_n)^T \in \mathbb{R}^n$ we define two quantities associated with the number of sign changes of the vector $\mathbf{c}$. These are:

$V^-(\mathbf{c})$ — the **number of sign changes in the sequence** $c_1, c_2, \ldots, c_n$ with the zero elements discarded; and

$V^+(\mathbf{c})$ — the **maximum number of sign changes in the sequence** $c_1, c_2, \ldots, c_n$, in which the zero elements are arbitrarily assigned the values $+1$ and -1.

For example, $V^-((1,0,1,-1,0,1)^T) = 2$ and $V^+((1,0,1,-1,0,1)^T) = 4$.

We use $<, \leq$ to denote the usual entry-wise partial order on matrices; i.e., for $A = [a_{ij}]$, $B = [b_{ij}] \in \mathbb{R}^{m \times n}$, $A \leq\ (<)\ B$ means $a_{ij} \leq\ (<)\ b_{ij}$, for all i, j.

Let S be the signature matrix whose diagonal entries alternate in sign beginning with $+1$. For $A, B \in \mathbb{R}^{m \times n}$, we write $A \overset{*}{\leq} B$ if and only if $SAS \leq SBS$ and $A \overset{*}{<} B$ if and only if $SAS < SBS$, and we call this the **"checkerboard" partial order** on real matrices.

The **Hadamard product** of two $m \times n$ matrices $A = [a_{ij}]$ and $B = [b_{ij}]$ is defined and denoted by

$$A \circ B = [a_{ij} b_{ij}].$$

If A is a $m \times n$ and entrywise nonnegative matrix, then $A^{(t)}$ denotes the tth **Hadamard power of** A, and is defined to be

$$A^{(t)} = [a_{ij}^t],$$

for any $t \geq 0$.

Facts:

1. [Sch30] Let A be an $m \times n$ real matrix with $m \geq n$. If A is totally positive, then $V^+(A\mathbf{x}) \leq V^-(\mathbf{x})$, for all nonzero $\mathbf{x} \in \mathbb{R}^n$.
2. [Sch30] Let A be an $m \times n$ real matrix with $m \geq n$. If A is totally nonnegative and of rank n, then $V^-(A\mathbf{x}) \leq V^-(\mathbf{x})$, for all nonzero $\mathbf{x} \in \mathbb{R}^n$.
3. [FJ11] Suppose that A is an $m \times n$ TN matrix. Then A is TP if and only if $V^+(A\mathbf{x}) \leq V^-(\mathbf{x})$ for all nonzero $\mathbf{x} \in \mathbb{R}^n$.
4. [GJ04] Suppose that $\mathbf{x} \in \mathbb{R}^n$, $\mathbf{y} \in \mathbb{R}^m$, and $\mathbf{x} \neq 0$. Then there is an $m \times n$ TP matrix A such that $A\mathbf{x} = \mathbf{y}$ if and only if $V^+(\mathbf{y}) \leq V^-(\mathbf{x})$ and if $V^+(\mathbf{y}) = V^-(\mathbf{x})$, then the signs of the initial nonzero entries of vectors dervied from $\mathbf{x}$ and $\mathbf{y}$ coincide.
5. Let $A = [a_{ij}]$ be an $n \times n$ totally nonnegative matrix. Then:
   (a) Hadamard: [GK02, pp. 91–97], [Kot53]
   $\det A \leq \prod_{i=1}^n a_{ii}$,
   (b) Fischer: [GK02, pp. 91–97], [Kot53] Let $S \subseteq N = \{1, 2, \ldots, n\}$,
   $\det A \leq \det A[S] \cdot \det A[N \setminus S]$,
   (c) Koteljanskii: [Kot53] Let S, $T \subseteq N$,
   $\det A[S \cup T] \cdot \det A[S \cap T] \leq \det A[S] \cdot \det A[T]$.

   The above three determinantal inequalities also hold for positive semidefinite matrices. (See Section 9.5.)
6. [FGJ03] Let $\alpha_1, \alpha_2, \beta_1$, and β_2 be subsets of $\{1, 2, \ldots, n\}$, and let A be any TN matrix. Then

   $$\det A[\alpha_1] \det A[\alpha_2] \leq \det A[\beta_1] \det A[\beta_2]$$

   if and only if each index i has the same multiplicity in the multiset $\alpha_1 \cup \alpha_2$ and the multiset $\beta_1 \cup \beta_2$, and $\max(|\alpha_1 \cap L|, |\alpha_2 \cap L|) \geq \max(|\beta_1 \cap L|, |\beta_2 \cap L|)$, for every contiguous (i.e., $d(L) = 0$) index set $L \subseteq \{1, 2, \ldots, n\}$ (see [FGJ03] for other classes of multiplicative principal-minor inequalities).
7. [Ska04], [BF08] Analogous non-principal minor inequalities (to those presented in Fact 6) have been produced for TP matrices in a effort to determine the multiplicative generators for all such determinantal inequalities.
8. [FJS00] Let A be an $n \times n$ totally nonnegative matrix with $\det A(\{1\}) \neq 0$. Then $A - xE_{11}$ is totally nonnegative for all $x \in [0, \frac{\det A}{\det A(\{1\})}]$.
9. [BJP82] If A is TN and invertible and $B = A[S]$, where $S \subseteq N$ is contiguous, then

B is invertible TN and

$$0 \leq (-1)^{i+j}(B^{-1})_{i,j} \leq (-1)^{i+j}(A^{-1})_{i,j},$$

for all $i, j \in S$.

10. [FJ98] Let A be an $n \times n$ TN matrix partitioned as follows:

$$A = \begin{bmatrix} A_{11} & \mathbf{b} \\ \mathbf{c}^T & d \end{bmatrix},$$

where A_{11} is $(n-1)\times(n-1)$. Suppose that $\operatorname{rank}(A_{11}) = p$. Then either $\operatorname{rank}([A_{11}, \mathbf{b}]) = p$ or $\operatorname{rank}[A_{11}^T, \mathbf{c}]^T = p$. See [FJ98] and [FJ11] (or [Pin08]) for other types of row and column inclusion results for TN matrices.

11. [Pin08], [FJ11] Under certain regulatory conditions a nice description on the distribution of zero minors in a TN matrix is provided and both represent a natural extension of the double echelon form mentioned in Section 29.1 and has become known as a shadow-type configuration casting to either the north-east or the south-west.
12. [CFJ01], [FJ07] If A and B are TN_k (TP_k), then $A \circ B$ need not be TN_k (TP_k) in general, unless $k = 2$, in which case $A \circ B$ is always TN_2 (TP_2), whenever A and B are TN_2 (TP_2).
13. [FJ07] If A is TP_k, then $A^{(t)}$ is TP_k for all $t \geq 1$, whenever $k \leq 3$, and if $k \geq 4$, then there exists a TN_k (TP_k) matrix for which some Hadamard power (at least one) is not TN_k (TP_k).
14. [CFJ01] Let T be an $n \times n$ totally nonnegative tridiagonal matrix. Then the Hadamard product of T with any other TN matrix is again TN.
15. [CFJ01], [Mar70b] The Hadamard product of any two $n \times n$ tridiagonal totally nonnegative matrices is again totally nonnegative.
16. [CFJ01] Let $A = \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$ be a 3×3 totally nonnegative matrix. Then A has the property that $A \circ B$ is TN for all B in TN if and only if

$$\begin{aligned} aei + gbf &\geq afh + dbi, \\ aei + dch &\geq afh + dbi. \end{aligned}$$

17. [CFJ01] Let A be an $n \times n$ totally nonnegative matrix with the property that $A \circ B$ is TN for all B in TN. Then

$$\det(A \circ B) \geq \det B \prod_{i=1}^{n} a_{ii},$$

for any $n \times n$ totally nonnegative matrix B.

18. [FJ07] Suppose A is an $m \times n$ matrix. Then A is TP_2 if and only if there exists some $T > 0$, such that for all $t \geq T$, $A^{(t)}$ is TP.
19. [Ste91] Let $A = [a_{ij}] \in \mathbb{R}^{n \times n}$, and let S_n denote the symmetric group on n symbols. If χ is an irreducible character of S_n, then the corresponding matrix function

$$[a_{ij}] \mapsto \sum_{\omega \in S_n} \chi(\omega) \prod_{i=1}^{n} a_{i,\omega(i)}$$

is called an *immanant*. For example, if χ is the trivial character $\chi(w) = 1$, then the corresponding immanant is the permanent and, if χ is $\operatorname{sgn}(\omega)$, then the immanant is the determinant. Every immanant of a totally nonnegative matrix is nonnegative.

20. [Gar96] If $A, B, C \in \mathbb{R}^{n\times n}$, $A \overset{*}{\leq} C \overset{*}{\leq} B$, and A and B are TP, then $\det C > 0$.
21. [Gar96] If $A, B, C \in \mathbb{R}^{n\times n}$, $A \overset{*}{\leq} C \overset{*}{\leq} B$, and A and B are TP, then C is TP.
22. [Gar96] If $A, B, C \in \mathbb{R}^{n\times n}$, $A \overset{*}{\leq} C \overset{*}{\leq} B$, and A and B are invertible and TN, then C is invertible and TN, whenever all of the *vertices* of the matrix interval defined by ordering on A and B above are invertible and TN.
23. [JN10] The Bruhat partial order on permutations is equivalent to a certain natural partial order induced by TP_2 matrices. Furthermore, a positive matrix is TP_2 if and only if it satisfies certain inequalities induced by the Bruhat partial order.

Examples:

1. Let

$$P_4 = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{bmatrix} \quad \text{and} \quad \text{let } \mathbf{x} = \begin{bmatrix} 1 \\ -2 \\ -5 \\ 4 \end{bmatrix}.$$

Then $V^-(\mathbf{x}) = 2$ and $P_4\mathbf{x} = [-2, -2, 5, 23]^T$, so $V^+(P_4\mathbf{x}) = 1$. Hence, Schoenberg's variation diminishing property (Fact 29.5.1) holds.

2. Let

$$H = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix} \quad \text{and} \quad \text{let } \mathbf{x} = \begin{bmatrix} 1 \\ -1 \\ -1 \\ 1 \end{bmatrix}.$$

Then $V^-(\mathbf{x}) = 2$ and $H\mathbf{x} = [0, -1, 0, 0]^T$, so $V^+(H\mathbf{x}) = 3$. Hence, Schoenberg's variation diminishing property (Fact 29.5.1) does not hold in general for TN matrices.

3. If $0 < A < B$ and $A, B \in \mathbb{R}^{n\times n}$ are TP, then not all matrices in the interval between A and B need be TP. Let

$$A = \begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 4 & 5 \\ 5 & 7 \end{bmatrix}.$$

Then A, B are TP and

$$C = \begin{bmatrix} 3 & 4 \\ 4 & 5 \end{bmatrix}$$

satisfies $A < C < B$, and C is not TP.

4. If TP is replaced by TN, then Fact 21 no longer holds. For example,

$$\begin{bmatrix} 2 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 1 \end{bmatrix} \overset{*}{\leq} \begin{bmatrix} 3 & 0 & 4 \\ 0 & 0 & 0 \\ 4 & 0 & 5 \end{bmatrix} \overset{*}{\leq} \begin{bmatrix} 4 & 0 & 5 \\ 0 & 0 & 0 \\ 5 & 0 & 7 \end{bmatrix};$$

however, both end matrices are TN while the middle matrix is not.

5. A polynomial $f(x)$ is *stable* if all the zeros of $f(x)$ have negative real parts, which is equivalent to the the Routh–Hurwitz matrix (Example 29.1.5) formed from f being invertible and totally nonnegative [Asn70]. Suppose $f(x) = \sum_{i=0}^{n} a_i x^i$ and $g(x) = \sum_{i=0}^{m} b_i x^i$ are two polynomials of degree n and m, respectively. Then the *Hadamard product of f and g* is the polynomial $(f \circ g)(x) = \sum_{i=0}^{k} a_i b_i x^i$, where $k = \min(m, n)$. In [GW96a], it is proved that the Hadamard product of stable polynomials is stable. Hence, the Hadamard product of two totally nonnegative Routh–Hurwitz matrices is in turn a totally nonnegative matrix [GW96a]. See also [GW96b] for a list of other subclasses of TN matrices that are closed under Hadamard multiplication.

6. Let $A = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$ and let $B = A^T$. Then A and B are TN, $A \circ B = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix}$, and $\det(A \circ B) = -1 < 0$. Thus, $A \circ B$ is not TN.
7. (Polya matrix) Let $q \in (0, 1)$. The $n \times n$ Polya matrix Q has its $(i, j)^{th}$ entry equal to q^{-2ij}. Then Q is totally positive for all n (see [Whi52]). In fact, Q is diagonally equivalent to a TP Vandermonde matrix. Suppose Q represents the 3×3 Polya matrix. Then Q satisfies that $Q \circ A$ is TN for all A TN whenever $q \in (0, \sqrt{1/\mu})$, where $\mu = \frac{1+\sqrt{5}}{2}$ (the golden mean).
8. The bidiagonal factorization (29.2) from Fact 29.2.5 for TN matrices was used in [Loe55] to show that for each nonsingular $n \times n$ TN matrix A there is a piece-wise continuous family of matrices $\Omega(t)$ of a special form such that the unique solution of the initial value problem

$$\frac{dA(t)}{dt} = \Omega(t)A(t), \; A(0) = I \tag{29.5}$$

has $A(1) = A$. Let $A(t) = [a_{ij}(t)]$ be a differentiable matrix-valued function of t such that $A(t)$ is nonsingular and TN for all $t \in [0, 1]$, and $A(0) = I$. Then

$$\Omega \equiv \left(\frac{dA(t)}{dt} \right)_{t=0} \tag{29.6}$$

is called an *infinitesimal element* of the semigroup of nonsingular TN matrices. By Eq. (29.2) every nonsingular TN matrix can be obtained from the solution of the initial value problem (29.5) in which all $\Omega(t)$ are infinitesimal elements.
9. If the main diagonal entries of a TP matrix are all equal to one, then it is not difficult to observe that as you move away from the diagonal there is a "drop off" effect in the entries of this matrix. Craven and Csordas [CC98] have worked out an enticing sufficient "drop off" condition for a matrix to be TP. If $A = [a_{ij}]$ is an $n \times n$ matrix with positive entries and satisfies

$$a_{ij}a_{i+1,j+1} \geq c_0 a_{i,j+1}a_{i+1,j},$$

where $c_0 = 4.07959562349...$, then A is TP. This condition is particularly appealing for both Hankel and Toeplitz matrices. Recall that a Hankel matrix is an $(n + 1) \times (n + 1)$ matrix of the form

$$\begin{bmatrix} a_0 & a_1 & \cdots & a_n \\ a_1 & a_2 & \cdots & a_{n+1} \\ \vdots & \vdots & \cdots & \vdots \\ a_n & a_{n+1} & \cdots & a_{2n} \end{bmatrix}.$$

So, if the positive sequence $\{a_i\}$ satisfies $a_{k-1}a_{k+1} \geq c_0 a_k^2$, then the corresponding Hankel matrix is TP. An $(n + 1) \times (n + 1)$ Toeplitz matrix is of the form

$$\begin{bmatrix} a_0 & a_1 & a_2 & \cdots & a_n \\ a_{-1} & a_0 & a_1 & \cdots & a_{n-1} \\ a_{-2} & a_{-1} & a_0 & \cdots & a_{n-2} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ a_{-n} & a_{-(n-1)} & a_{-(n-2)} & \cdots & a_0 \end{bmatrix}.$$

Hence, if the positive sequence $\{a_i\}$ satisfies $a_k^2 \geq c_0 a_{k-1}a_{k+1}$, then the corresponding Toeplitz matrix is TP. The exact value of c_0 was determined in [KV06].
10. A sequence $a_0, a_1, \ldots$ of real numbers is called *totally nonnegative* if the two-way infinite

matrix given by

$$\begin{bmatrix} a_0 & 0 & 0 & \cdots \\ a_1 & a_0 & 0 & \cdots \\ a_2 & a_1 & a_0 & \cdots \\ \vdots & \vdots & \vdots & \end{bmatrix}$$

is TN. As expected, an infinite matrix is TN if all of its minors are nonnegative. Notice that the above matrix is a Toeplitz matrix. Studying the functions that generate totally nonnegative sequences was a difficult and important step in the area of totally nonnegative matrices; $f(x)$ generates the sequence $a_0, a_1, \ldots$ if $f(x) = a_0 + a_1 x + a_2 x^2 + \cdots$. In Aissen et al. [ASW52] (see also [Edr52]), it was shown that the above two-way infinite Toeplitz matrix is TN (i.e., the corresponding sequence is totally nonnegative) if and only if the generating function $f(x)$ for the sequence $a_0, a_1, \ldots$ has the form

$$f(x) = e^{\gamma x} \frac{\prod_{\nu=1}^{\infty}(1 + \alpha_v x)}{\prod_{\nu=1}^{\infty}(1 - \beta_v x)},$$

where $\gamma, \alpha_v, \beta_v \geq 0$, and $\sum \alpha_v$ and $\sum \beta_v$ are convergent.

Linear Preserver Problems

Peter Šemrl
University of Ljubljana

30.1 Basic Concepts 30-1
30.2 Standard Forms 30-2
30.3 Standard Linear Preserver Problems 30-4
30.4 Additive, Multiplicative, and Nonlinear Preservers 30-8
References 30-9

Linear preservers are linear maps on linear spaces of matrices that leave certain subsets, properties, relations, functions, etc. invariant. Linear preserver problems ask what is the general form of such maps. Describing the structure of such maps often gives a deeper understanding of the matrix sets, functions, or relations under the consideration. Some of the linear preserver problems are motivated by applications (system theory, quantum mechanics, etc.).

30.1 Basic Concepts

Definitions:

Let $\mathcal{V}$ be a linear subspace of $F^{m\times n}$. Let f be a (scalar-valued, vector-valued, or set-valued) function on $\mathcal{V}$, $\mathcal{M}$ a subset of $\mathcal{V}$, and $\sim$ a relation defined on $\mathcal{V}$.

A linear map $\phi : \mathcal{V} \to \mathcal{V}$ is called a **linear preserver of function** f if $f(\phi(A)) = f(A)$ for every $A \in \mathcal{V}$.

A linear map $\phi : \mathcal{V} \to \mathcal{V}$ **preserves** $\mathcal{M}$ if $\phi(\mathcal{M}) \subseteq \mathcal{M}$.

The map ϕ **strongly preserves** $\mathcal{M}$ if $\phi(\mathcal{M}) = \mathcal{M}$.

A linear map $\phi : \mathcal{V} \to \mathcal{V}$ **preserves the relation** $\sim$ if $\phi(A) \sim \phi(B)$ whenever $A \sim B$, $A, B \in \mathcal{V}$.

If for every pair $A, B \in \mathcal{V}$ we have $\phi(A) \sim \phi(B)$ if and only if $A \sim B$, then ϕ **strongly preserves the relation** $\sim$.

Facts:

1. If linear maps $\phi : \mathcal{V} \to \mathcal{V}$ and $\psi : \mathcal{V} \to \mathcal{V}$ both preserve $\mathcal{M}$, then $\phi\psi : \mathcal{V} \to \mathcal{V}$ preserves $\mathcal{M}$. Consequently, the set of all linear transformations on $\mathcal{V}$ preserving $\mathcal{M}$ is a multiplicative semigroup.
2. The set of all bijective linear transformations strongly preserving $\mathcal{M}$ is a multiplicative group.
3. [BLL92, p. 41] Let $\mathcal{M} \subseteq \mathcal{V}$ be an algebraic subset and $\phi : \mathcal{V} \to \mathcal{V}$ a bijective linear map satisfying $\phi(\mathcal{M}) \subseteq \mathcal{M}$. Then ϕ strongly preserves $\mathcal{M}$.

Examples:

1. Let $R \in F^{m\times m}$ and $S \in F^{n\times n}$. The linear map $\phi\colon F^{m\times n} \to F^{m\times n}$ defined by $\phi(A) = RAS$, $A \in F^{m\times n}$, preserves the set of all matrices of rank at most one. In general, such a map does not preserve this set strongly.
2. If R and S in the previous example are invertible, then ϕ is a bijective linear map strongly preserving matrices of rank one. In fact, such a map ϕ strongly preserves matrices of rank k, $k = 1, \ldots, \min\{m, n\}$.
3. If $m = n$ and $R, S \in F^{n\times n}$, then the linear map $A \mapsto RA^TS$, $A \in F^{n\times n}$, preserves matrices of rank at most one. If both R and S are invertible, then ϕ strongly preserves the set of all matrices of rank k, $1 \le k \le n$.
4. Assume that $m = n$. Let $R \in F^{n\times n}$ be an invertible matrix, c a nonzero scalar, and $f : F^{n\times n} \to F$ a linear functional. Then both maps $A \mapsto cRAR^{-1} + f(A)I$, $A \in F^{n\times n}$, and $A \mapsto cRA^TR^{-1} + f(A)I$, $A \in F^{n\times n}$, strongly preserve commutativity; that is, if $\phi : F^{n\times n} \to F^{n\times n}$ is any of these two maps, then for every pair $A, B \in F^{n\times n}$ we have $\phi(A)\phi(B) = \phi(B)\phi(A)$ if and only if $AB = BA$.
5. Let $\|\cdot\|$ be any norm on $\mathbb{C}^{m\times n}$. A linear map $\phi : \mathbb{C}^{m\times n} \to \mathbb{C}^{m\times n}$ is called an isometry if $\|\phi(A)\| = \|A\|$, $A \in \mathbb{C}^{m\times n}$. Thus, isometries are linear preservers of norm functions.
6. Let $1 \le k < \min\{m, n\}$. A matrix $A \in F^{m\times n}$ is of rank at most k if the determinant of every $(k+1)\times(k+1)$ submatrix of A is zero. Thus, the set of all $m \times n$ matrices of rank at most k is an algebraic subset of $F^{m\times n}$.
7. The set of all nilpotent $n \times n$ matrices is an algebraic subset of $F^{n\times n}$. More generally, given a polynomial $p \in F[X]$, the set of all matrices $A \in F^{n\times n}$ satisfying $p(A) = 0$ is an algebraic set. Hence, bijective linear maps on $F^{n\times n}$ preserving idempotent matrices, nilpotents, involutions, etc. preserve these sets strongly.

30.2 Standard Forms

Definitions:

Let $\mathcal{V}$ be a linear subspace of $F^{m\times n}$ and let P be a preserving property which makes sense for linear maps acting on $\mathcal{V}$ (P may be the property of preserving a certain subset of $\mathcal{V}$ or the property of preserving a certain relation on $\mathcal{V}$ or the property of preserving a certain function defined on $\mathcal{V}$). A **linear preserver problem** corresponding to the property P is the problem of characterizing all linear (bijective) maps on $\mathcal{V}$ satisfying this property. Very often, linear preservers have the standard forms (see the next section). Occasionally, there are interesting exceptional cases especially in low dimensions (see later examples).

Let $R \in F^{m\times m}$ and $S \in F^{n\times n}$ be invertible matrices. A map $\phi : F^{m\times n} \to F^{m\times n}$ is called an (R, S)-**standard map** if either $\phi(A) = RAS$, $A \in F^{m\times n}$, or $m = n$ and $\phi(A) = RA^TS$, $A \in F^{n\times n}$. In many cases we assume that R and S satisfy some additional assumptions.

Let $R \in F^{n\times n}$ be an invertible matrix, c a nonzero scalar, and $f : F^{n\times n} \to F$ a linear functional. A map $\phi : F^{n\times n} \to F^{n\times n}$ is called an (R, c, f)-**standard map** if either $\phi(A) = cRAR^{-1} + f(A)I$, $A \in F^{n\times n}$, or $\phi(A) = cRA^TR^{-1} + f(A)I$, $A \in F^{n\times n}$.

When we consider linear preservers on proper subspaces $\mathcal{V} \subset F^{m\times n}$, we usually have to modify the notion of standard maps. Let us consider the case when $\mathcal{V} = \mathcal{T}_n \subset F^{n\times n}$ is the subalgebra of all upper triangular matrices. The **flip map** $A \mapsto A^f$, $A \in \mathcal{T}_n$, is defined as the transposition over the antidiagonal; that is, $A^f = GA^TG$, where $G = E_{1n} + E_{2,n-1} + \ldots + E_{n1}$ (see Example 1). Standard maps on $\mathcal{T}_n$ are maps of the form

$$A \mapsto RAS, \quad A \in \mathcal{T}_n,$$

$$A \mapsto RA^fS, \quad A \in \mathcal{T}_n,$$

$$A \mapsto cRAR^{-1} + f(A)I, \quad A \in \mathcal{T}_n,$$

and

$$A \mapsto cRA^f R^{-1} + f(A)I, \quad A \in \mathcal{T}_n,$$

where R and S are invertible upper triangular matrices, c is a nonzero scalar, and f is a linear functional on $\mathcal{T}_n$.

Facts:

1. Every (R, S)-standard map is bijective. It strongly preserves matrices of rank k, $k = 1, \dots, \min\{m, n\}$. Every (R, c, f)-standard map is either bijective, or its kernel is the one-dimensional subspace consisting of all scalar matrices.
2. Let $U \in \mathbb{C}^{m\times m}$ and $V \in \mathbb{C}^{n\times n}$ be unitary matrices. Then a (U, V)-standard map preserves singular values and, hence, all functions of singular values including unitarily invariant norms.
3. Let $R \in \mathbb{C}^{n\times n}$ be an invertible matrix. Then an (R, R^{-1})-standard map on $\mathbb{C}^{n\times n}$ preserves spectrum, idempotents, nilpotents, similarity, zero products, etc.
4. If $U \in \mathbb{C}^{n\times n}$ is a unitary matrix, then a (U, U^*)-standard map defined on $\mathbb{C}^{n\times n}$ strongly preserves the set of all orthogonal idempotents, the set of all normal matrices, numerical range, etc.
5. If $A, B \in \mathcal{T}_n$, then $(AB)^f = B^f A^f$.

Examples:

1. $$\begin{bmatrix} a & b & c & d \\ 0 & e & f & g \\ 0 & 0 & h & i \\ 0 & 0 & 0 & j \end{bmatrix}^f = \begin{bmatrix} j & i & g & d \\ 0 & h & f & c \\ 0 & 0 & e & b \\ 0 & 0 & 0 & a \end{bmatrix}.$$
2. A map $\phi : \mathbb{C}^{2\times 2} \to \mathbb{C}^{2\times 2}$ given by
$$\phi\left(\begin{bmatrix} a & b \\ c & d \end{bmatrix}\right) = \begin{bmatrix} a & -b \\ c & d \end{bmatrix}$$
is a bijective linear map that strongly preserves commutativity but is not of a standard form. More generally, any bijective linear map $\phi : \mathbb{C}^{2\times 2} \to \mathbb{C}^{2\times 2}$ satisfying $\phi(I) = I$ strongly preserves commutativity [Kun99]. In higher dimensions, there are no nonstandard bijective linear maps preserving commutativity [BLL92, p. 76].
3. Let $\mathcal{W} \subset \mathbb{C}^{n\times n}$ be any linear subspace of matrices with the property that $AB = BA$ for every pair $A, B \in \mathcal{W}$. Assume that $\phi : \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ is a linear map whose range is contained in $\mathcal{W}$. Then ϕ is a nonstandard map preserving commutativity. If $n > 1$, then it does not preserve commutativity strongly. A map $\phi : \mathbb{C}^{2\times 2} \to \mathbb{C}^{2\times 2}$ defined by
$$\phi\left(\begin{bmatrix} a & b \\ c & d \end{bmatrix}\right) = \begin{bmatrix} a & b \\ -b & a \end{bmatrix}$$
is a concrete example of such a map.
4. A map $\phi : \mathbb{R}^{4\times 4} \to \mathbb{R}^{4\times 4}$ given by
$$\phi\left(\begin{bmatrix} a & b & c & d \\ * & * & * & * \\ * & * & * & * \\ * & * & * & * \end{bmatrix}\right) = \begin{bmatrix} a & b & c & d \\ -b & a & -d & c \\ -c & d & a & -b \\ -d & -c & b & a \end{bmatrix}$$

preserves the real orthogonal group, that is, $\phi(O)$ is an orthogonal matrix for every orthogonal matrix $O \in \mathbb{R}^{4\times 4}$. Note that the right-hand side of the previous equation is the standard matrix representation of the quaternion $a + bi + cj + dk$. Similar constructions with matrix representations of complex and Cayley numbers give nonstandard linear preservers of real orthogonal group on $\mathbb{R}^{2\times 2}$ and $\mathbb{R}^{8\times 8}$. If $\phi : \mathbb{R}^{n\times n} \to \mathbb{R}^{n\times n}$ is a linear preserver of orthogonal group and $n \notin \{2, 4, 8\}$, then ϕ is a (U, V)-standard map with U and V being orthogonal matrices [LP01, p. 601].

5. A linear map ϕ acting on 4×4 upper triangular matrices given by

$$\begin{bmatrix} a & b & c & d \\ 0 & e & f & g \\ 0 & 0 & h & i \\ 0 & 0 & 0 & j \end{bmatrix} \mapsto \begin{bmatrix} e & f & g & b \\ 0 & j & i & c \\ 0 & 0 & h & d \\ 0 & 0 & 0 & a \end{bmatrix}$$

is a nonstandard bijective linear map strongly preserving the set of invertible matrices. All that is important in this example is that A and $\phi(A)$ have the same diagonal entries up to a permutation.

30.3 Standard Linear Preserver Problems

Definitions:

Linear preserver problems ask what is the general form of (bijective) linear maps on matrix spaces having a certain preserving property. When the general form of linear preservers under the consideration is one of the standard forms, we speak of a **standard linear preserver problem**. The following list of some of the most important standard linear preserver results is far from being complete. Many more results can be found in the survey [BLL92].

Facts:

1. [BLL92, Theorem 2.2], [LT92, Prop. 3] Let m, n be positive integers and $\phi : \mathbb{C}^{m\times n} \to \mathbb{C}^{m\times n}$ a linear map. Assume that one of the following two conditions is satisfied:
   - Let k be a positive integer, $k \leq \min\{m, n\}$, and assume that $\operatorname{rank}\phi(A) = k$ whenever $\operatorname{rank} A = k$.
   - ϕ is invertible and $\operatorname{rank}\phi(A) = \operatorname{rank}\phi(B)$ whenever $\operatorname{rank} A = \operatorname{rank} B$.

   Then ϕ is an (R, S)-standard map for some invertible matrices $R \in \mathbb{C}^{m\times m}$ and $S \in \mathbb{C}^{n\times n}$.
2. [BLL92, p. 9] Let F be a field with more than three elements, k a positive integer, $k \leq \min\{m, n\}$, and $\phi : F^{m\times n} \to F^{m\times n}$ an invertible linear map such that $\operatorname{rank}\phi(A) = k$ whenever $\operatorname{rank} A = k$. Then ϕ is an (R, S)-standard map for some invertible matrices $R \in F^{m\times m}$ and $S \in F^{n\times n}$.
3. [BLL92, Theorem 2.6] Let $\phi : F^{m\times n} \to F^{p\times q}$ be a linear map such that $\operatorname{rank}\phi(A) \leq 1$ whenever $\operatorname{rank} A = 1$. Then either
   (a) $\phi(A) = RAS$ for some $R \in F^{p\times m}$ and some $S \in F^{n\times q}$ or
   (b) $\phi(A) = RA^T S$ for some $R \in F^{p\times n}$ and some $S \in F^{m\times q}$ or
   (c) the range of ϕ is contained in the set of all matrices of rank at most one.
4. [BLL92, p. 10] Let F be an infinite field with characteristic $\neq 2$, $\mathcal{S}_n$ the space of all $n \times n$ symmetric matrices over F, and let k be an integer, $1 \leq k \leq n$. If $\phi : \mathcal{S}_n \to \mathcal{S}_n$

is an invertible linear rank k preserver, then $\phi(A) = cRAR^T$ for every $A \in \mathcal{S}$. Here, c is a nonzero scalar and R an invertible $n \times n$ matrix.

5. [BLL92, Theorem 2.9] Let F be a field with characteristic $\neq 2$. Assume that F has more than three elements. Let $\phi : \mathcal{S}_n \to \mathcal{S}_m$ be a linear map such that $\operatorname{rank} \phi(A) \leq 1$ whenever $\operatorname{rank} A = 1$. Then either
   (a) there exist an $m \times n$ matrix R and a scalar c such that $\phi(A) = cRAR^T$ or
   (b) the range of ϕ is contained in a linear span of some rank one $m \times m$ symmetric matrix.

6. [BLL92, Theorem 2.7, Theorem 2.8, p. 25] Let ϕ be a real linear map acting on the real linear space $\mathcal{H}_n$ of all $n \times n$ Hermitian complex matrices. Let π, ν, δ be nonnegative integers with $\pi + \nu + \delta = n$ and denote by $G(\pi, \nu, \delta)$ the set of all $A \in \mathcal{H}_n$ with inertia $\operatorname{in}(A) = (\pi, \nu, \delta)$. Assume that one of the following is satisfied:

   - $n \geq 3$, $k < n$, ϕ is invertible, and $\operatorname{rank} \phi(A) \leq k$ whenever $\operatorname{rank} A = k$.
   - $n \geq 2$, the range of ϕ is not one-dimensional, and $\operatorname{rank} \phi(A) = 1$ whenever $\operatorname{rank} A = 1$.
   - The triple (π, ν, δ) does not belong to the set $\{(n, 0, 0), (0, n, 0), (0, 0, n)\}$, ϕ is bijective, and $\phi(G(\pi, \nu, \delta)) \subseteq G(\pi, \nu, \delta)$.

   Then there exist an invertible $n \times n$ complex matrix R and a constant $c \in \{-1, 1\}$ such that either

   (a) $\phi(A) = cRAR^*$ for every $A \in \mathcal{H}_n$ or
   (b) $\phi(A) = cRA^TR^*$ for every $A \in \mathcal{H}_n$.

   Of course, if the third of the above conditions is satisfied, then the possibility $c = -1$ can occur only when $\pi = \nu$.

7. [BLL92, p. 76] Let $n \geq 3$ and let $\phi : F^{n \times n} \to F^{n \times n}$ be an invertible linear map such that $\phi(A)\phi(B) = \phi(B)\phi(A)$ whenever A and B commute. Then ϕ is an (R, c, f)-standard map for some invertible $R \in F^{n \times n}$, some nonzero scalar c, and some linear functional $f : F^{n \times n} \to F$.
8. [LP01, Theorem 2.3] Let $\phi : \mathbb{C}^{n \times n} \to \mathbb{C}^{n \times n}$ be a linear similarity preserving map. Then either
   (a) ϕ is an (R, c, f)-standard map or
   (b) $\phi(A) = (\operatorname{tr} A)B$, $A \in \mathbb{C}^{n \times n}$.

   Here, $B, R \in \mathbb{C}^{n \times n}$ and R is invertible, c is a nonzero complex number, and $f : \mathbb{C}^{n \times n} \to \mathbb{C}$ is a functional of the form $f(A) = b\operatorname{tr} A$, $A \in \mathbb{C}^{n \times n}$, for some $b \in \mathbb{C}$.
9. [BLL92, p. 77] Let ϕ be a real-linear unitary similarity preserving map on $\mathcal{H}_n$. Then either
   (a) $\phi(A) = (\operatorname{tr} A)B$, $A \in \mathcal{H}_n$ or
   (b) $\phi(A) = cUAU^* + b(\operatorname{tr} A)I$, $A \in \mathcal{H}_n$ or
   (c) $\phi(A) = cUA^TU^* + b(\operatorname{tr} A)I$, $A \in \mathcal{H}_n$.

   Here, B is a Hermitian matrix, U is a unitary matrix, and b, c are real constants.
10. [BLL92, Theorem 4.7.6] Let $n > 2$ and let F be an algebraically closed field of characteristic zero. Let p be a polynomial of degree n with at least two distinct roots. Let us write p as $p(x) = x^k q(x)$ with $k \geq 0$ and $q(0) \neq 0$. Assume that $\phi : F^{n \times n} \to F^{n \times n}$ is an invertible linear map preserving the set of all matrices annihilated by p. Then either
    (a) $\phi(A) = cRAR^{-1}$, $A \in F^{n \times n}$ or
    (b) $\phi(A) = cRA^TR^{-1}$, $A \in F^{n \times n}$.

Here, R is an invertible matrix and c is a constant permuting the roots of q; that is, $q(c\lambda) = 0$ for each $\lambda \in F$ satisfying $q(\lambda) = 0$.

11. [BLL92, p. 48] Let $sl_n \subset F^{n\times n}$ be the linear space of all trace zero matrices and $\phi\colon sl_n \to sl_n$ an invertible linear map preserving the set of all nilpotent matrices. Then there exist an invertible matrix $R \in F^{n\times n}$ and a nonzero scalar c such that either

    (a) $\phi(A) = cRAR^{-1}$, $A \in sl_n$ or
    (b) $\phi(A) = cRA^TR^{-1}$, $A \in sl_n$.

    When considering linear preservers of nilpotent matrices one should observe first that the linear span of all nilpotent matrices is sl_n and, therefore, it is natural to confine maps under consideration to this subspace of codimension one.

12. [GLS00, pp. 76, 78] Let F be an algebraically closed field of characteristic 0, m, n positive integers, and $\phi\colon F^{n\times n} \to F^{m\times m}$ a linear transformation. If ϕ is nonzero and maps idempotent matrices to idempotent matrices, then $m \geq n$ and there exist an invertible matrix $R \in F^{m\times m}$ and nonnegative integers k_1, k_2 such that $1 \leq k_1 + k_2$, $(k_1 + k_2)n \leq m$ and

    $$\phi(A) = R(A \oplus \ldots \oplus A \oplus A^T \oplus \ldots \oplus A^T \oplus 0)R^{-1}$$

    for every $A \in F^{n\times n}$. In the above block diagonal direct sum the matrix A appears k_1 times, A^T appears k_2 times, and 0 is the zero matrix of the appropriate size (possibly absent). If $p \in F[X]$ is a polynomial of degree > 1 with simple zeros (each zero has multiplicity one), ϕ is unital and maps every $A \in F^{n\times n}$ satisfying $p(A) = 0$ into some $m \times m$ matrix annihilated by p, then ϕ is of the above described form with $(k_1 + k_2)n = m$.

13. [BLL92, Theorem 4.6.2] Let $\phi\colon \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ be a linear map preserving the unitary group. Then ϕ is a (U, V)-standard map for some unitary matrices $U, V \in \mathbb{C}^{n\times n}$.

14. [KH92] Let $\phi\colon \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ be a linear map preserving normal matrices. Then either

    (a) $\phi(A) = cUAU^* + f(A)I$, $A \in \mathbb{C}^{n\times n}$ or
    (b) $\phi(A) = cUA^tU^* + f(A)I$, $A \in \mathbb{C}^{n\times n}$ or
    (c) the range of ϕ is contained in the set of normal matrices.

    Here, U is a unitary matrix, c is a nonzero scalar, and f is a linear functional on $\mathbb{C}^{n\times n}$.

15. [LP01, p. 595] Let $\|\cdot\|$ be a unitarily invariant norm on $\mathbb{C}^{m\times n}$ that is not a multiple of the Frobenius norm defined by $\|A\| = \sqrt{\operatorname{tr}(AA^*)}$. The group of linear preservers of $\|\cdot\|$ on $\mathbb{C}^{m\times n}$ is the group of all (U, V)-standard maps, where $U \in \mathbb{C}^{m\times m}$ and $V \in \mathbb{C}^{n\times n}$ are unitary matrices. Of course, if $\|\cdot\|$ is a mulitple of the Frobenious norm, then the group of linear preservers of $\|\cdot\|$ on $\mathbb{C}^{m\times n}$ is the group of all unitary operators, i.e., those linear operators $\phi\colon \mathbb{C}^{m\times n} \to \mathbb{C}^{m\times n}$ that preserve the usual inner product $\langle A, B\rangle = \operatorname{tr}(AB^*)$ on $\mathbb{C}^{m\times n}$.

16. [BLL92, pp. 63–64] Let $\phi\colon \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ be a linear map preserving the numerical radius. Then either

    (a) $\phi(A) = cUAU^*$, $A \in \mathbb{C}^{n\times n}$ or
    (b) $\phi(A) = cUA^TU^*$, $A \in \mathbb{C}^{n\times n}$.

    Here, U is a unitary matrix and c a complex constant with $|c| = 1$.

17. [BLL92, Theorem 4.3.1] Let $n > 2$ and let $\phi\colon F^{n\times n} \to F^{n\times n}$ be a linear map preserving the permanent. Then ϕ is an (R, S)-standard map, where R and S are each a product of a diagonal and a permutation matrix, and the product of the two diagonal matrices has determinant one.

18. [CL98] Let $\phi : \mathcal{T}_n \to \mathcal{T}_n$ be a linear rank one preserver. Then either
    (a) the range of ϕ is the space of all matrices of the form

$$\begin{bmatrix} * & * & \dots & * \\ 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 \end{bmatrix}$$

    or

    (b) the range of ϕ is the space of all matrices of the form

$$\begin{bmatrix} 0 & 0 & \dots & 0 & * \\ 0 & 0 & \dots & 0 & * \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 0 & * \end{bmatrix}$$

    or

    (c) $\phi(A) = RAS$ for some invertible $R, S \in \mathcal{T}_n$ or
    (d) $\phi(A) = RA^f S$ for some invertible $R, S \in \mathcal{T}_n$.

Examples:

1. Let $n \geq 2$. Then the linear map $\phi : \mathcal{T}_n \to \mathcal{T}_n$ defined by

$$\phi\left(\begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ 0 & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & a_{nn} \end{bmatrix}\right)$$

$$= \begin{bmatrix} a_{11} + a_{22} + \ldots + a_{nn} & a_{12} + a_{23} + \ldots + a_{n-1,n} & \cdots & a_{1n} \\ 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 \end{bmatrix}$$

is an example of a singular preserver of rank one.

2. The most important example of a nonstandard linear preserver problem is the problem of characterizing linear maps on $n \times n$ real or complex matrices preserving the set of positive semidefinite matrices. Let $R_1, \dots, R_r, S_1, \dots, S_k$ be $n \times n$ matrices. Then the linear map ϕ given by $\phi(A) = R_1 A R_1^* + \cdots + R_r A R_r^* + S_1 A^T S_1^* + \cdots + S_k A^T S_k^*$ is a linear preserver of positive semidefinite matrices. Such a map is called decomposable. In general, it cannot be reduced to a single congruence or a single congruence composed with the transposition. Moreover, there exist linear maps on the space of $n \times n$ matrices preserving positive semidefinite matrices that are not decomposable. There is no general structural result for such maps.

30.4 Additive, Multiplicative, and Nonlinear Preservers

Definitions:

A map $\phi : F^{m\times n} \to F^{m\times n}$ is **additive** if $\phi(A+B) = \phi(A) + \phi(B)$, $A, B \in F^{m\times n}$. An additive map $\phi : F^{m\times n} \to F^{m\times n}$ having a certain preserving property is called an **additive preserver**.

A map $\phi : F^{n\times n} \to F^{n\times n}$ is **multiplicative** if $\phi(AB) = \phi(A)\phi(B)$, $A, B \in F^{n\times n}$. A multiplicative map $\phi : F^{n\times n} \to F^{n\times n}$ having a certain preserving property is called a **multiplicative preserver**.

Two matrices $A, B \in F^{m\times n}$ are said to be **adjacent** if $\operatorname{rank}(A - B) = 1$.

A map $\phi : F^{n\times n} \to F^{n\times n}$ is called a **local similarity** if for every $A \in F^{n\times n}$ there exists an invertible $R_A \in F^{n\times n}$ such that $\phi(A) = R_A A R_A^{-1}$.

Let $f : F \to F$ be an automorphism of the field F. A map $\phi : F^{n\times n} \to F^{n\times n}$ defined by $\phi([a_{ij}]) = [f(a_{ij})]$ is called a **ring automorphism of $F^{n\times n}$ induced by f**.

Facts:

1. [BS00] Let $n \geq 2$ and assume that $\phi : F^{n\times n} \to F^{n\times n}$ is a surjective additive map preserving rank one matrices. Then there exist a pair of invertible matrices $R, S \in F^{n\times n}$ and an automorphism f of the field F such that ϕ is a composition of an (R, S)-standard map and a ring automorphism of $F^{n\times n}$ induced by f.
2. [GLR03] Let $SL(n, \mathbb{C})$ denote the group of all $n \times n$ complex matrices A such that $\det A = 1$. A multiplicative map $\phi : SL(n, \mathbb{C}) \to \mathbb{C}^{n\times n}$ satisfies $\rho(\phi(A)) = \rho(A)$ for every $A \in SL(n, \mathbb{C})$ if and only if there exists $S \in SL(n, \mathbb{C})$ such that either
   (a) $\phi(A) = SAS^{-1}$, $A \in SL(n, \mathbb{C})$ or
   (b) $\phi(A) = S\overline{A}S^{-1}$, $A \in SL(n, \mathbb{C})$.

   Here, $\overline{A}$ denotes the matrix obtained from A by applying the complex conjugation entrywise.
3. [Sem08] Let $n \geq 3$ and let $\phi : \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ be a continuous mapping. Then ϕ preserves spectrum and commutativity (no linearity, additivity, or multiplicativity is assumed) if and only if there exists an invertible matrix $R \in \mathbb{C}^{n\times n}$ such that ϕ is an (R, R^{-1})-standard map.
4. [BR00] Let $\phi : \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ be a spectrum preserving C^1-diffeomorphism (again, we do not assume that ϕ is additive or multiplicative). Then ϕ is a local similarity.
5. [HS08] Let m, n be positive integers with $n \geq 2$. Assume that $\phi : \mathcal{H}_n \to \mathcal{H}_m$ is a map such that the matrices $\phi(A)$ and $\phi(B)$ are adjacent whenever A and B are adjacent, $A, B \in \mathcal{H}_n$. Suppose that $\phi(0) = 0$. Then one of the following holds.
   (a) There exist a rank one matrix $R \in \mathcal{H}_m$ and a function $\rho : \mathcal{H}_n \to \mathbb{R}$ such that $\phi(A) = \rho(A)R$.
   (b) $m \geq n$ and there exist $c \in \{-1, 1\}$ and an invertible $m \times m$ complex matrix T such that either $\phi(A) = cT \begin{bmatrix} A & 0 \\ 0 & 0 \end{bmatrix} T^*$, $A \in \mathcal{H}_n$, or $\phi(A) = cT \begin{bmatrix} \overline{A} & 0 \\ 0 & 0 \end{bmatrix} T^*$, $A \in \mathcal{H}_n$.
6. [Mol01] Let $n \geq 2$ be an integer and $\phi : \mathcal{H}_n \to \mathcal{H}_n$ a bijective map such that $\phi(A) \leq \phi(B)$ if and only if $A \leq B$, $A, B \in \mathcal{H}_n$ (here, $A \leq B$ if and only if $B - A$ is a positive semidefinite matrix). Then there exist an invertible $R \in \mathbb{C}^{n\times n}$ and $S \in \mathcal{H}_n$ such that either
   (a) $\phi(A) = RAR^* + S$, $A \in \mathcal{H}_n$ or
   (b) $\phi(A) = R\overline{A}R^* + S$, $A \in \mathcal{H}_n$.

This result has an infinite-dimensional analog important in quantum mechanics. In the language of quantum mechanics, the relation $A \leq B$ means that the expected value of the bounded observable A in any state is less than or equal to the expected value of B in the same state.

Examples:

1. We define a mapping $\phi : \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ in the following way. For a diagonal matrix A with distinct diagonal entries, we define $\phi(A)$ to be the diagonal matrix obtained from A by interchanging the first two diagonal elements. Otherwise, let $\phi(A)$ be equal to A. Clearly, ϕ is a bijective mapping preserving spectrum and commutativity in both directions. This shows that the continuity assumption is indispensable in Fact 3.
2. Let $\phi : \mathbb{C}^{n\times n} \to \mathbb{C}^{n\times n}$ be a map defined by $\phi(0) = E_{12}$, $\phi(E_{12}) = 0$, and $\phi(A) = A$ for all $A \in \mathbb{C}^{n\times n} \setminus \{0, E_{12}\}$. Then ϕ is a bijective spectrum preserving map that is not a local similarity. More generally, we can decompose $\mathbb{C}^{n\times n}$ into the disjoint union of the classes of matrices having the same spectrum and then any bijection leaving each of these classes invariant preserves spectrum. Thus, the assumption on differentiability is essential in Fact 4.

31.1 Counting Matrices with a Given Property

Let F denote a finite field with q elements, i.e., $F = GF(q)$, where $q = p^k$ for some positive integer k and prime p. Since the number of $n \times m$ matrices over F is finite ($|F^{n\times m}| = q^{nm}$), a number of results have appeared which count matrices with various properties. The following is a selection of some of these results.

Definitions:

A matrix $A \in F^{n\times n}$ is **orthogonal** if $A^T A = I_n$.

A matrix $A \in F^{n\times n}$ is **nonderogatory** if its minimum and characteristic polynomials are equal.

The **Euler function** $\phi(f(x))$ for polynomials over F is defined as the number of monic polynomials over F which are of the same degree as $f(x)$ and relatively prime to $f(x)$.

Facts:

Proofs of the following facts can be found in [FA66], [CH56], or [Mac69].

1. Let $\mathbf{0} \neq \mathbf{v} \in F^m$ and $\mathbf{w} \in F^n$ be fixed vectors. The number of $n \times m$ matrices over F that map $\mathbf{v}$ to $\mathbf{w}$ is equal to $q^{n(m-1)}$.
2. Let $\mathbf{0} \neq \mathbf{v} \in F^n$ and $\mathbf{0} \neq \mathbf{w} \in F^n$ be fixed vectors. The number of nonsingular matrices of order n over F that map $\mathbf{v}$ to $\mathbf{w}$ is equal to $\prod_{j=1}^{n-1}(q^n - q^j)$.
3. The number of nonsingular matrices of order n over F is equal to $\prod_{j=0}^{n-1}(q^n - q^j)$.
4. The number of $n \times m$ matrices over F with rank r is equal to

$$\frac{\prod_{j=0}^{r-1}(q^n - q^j)\prod_{j=0}^{r-1}(q^m - q^j)}{\prod_{j=0}^{r-1}(q^r - q^j)}.$$

5. The number of symmetric matrices of order n over F with rank r is equal to

$$\prod_{j=1}^{\frac{r}{2}} \frac{q^{2j}}{q^{2j}-1} \prod_{j=0}^{r-1}(q^{n-j} - 1), \text{ if } r \text{ is even}$$

or

$$\prod_{j=1}^{\frac{r-1}{2}} \frac{q^{2j}}{q^{2j}-1} \prod_{j=0}^{r-1}(q^{n-j}-1), \text{ if } r \text{ is odd}$$

6. If the characteristic of F is 2, then the number of symmetric matrices of order n over F with zero diagonal and rank r is equal to

$$\prod_{j=1}^{\frac{r}{2}} \frac{q^{2j-2}}{q^{2j}-1} \prod_{j=0}^{r-1}(q^{n-j}-1), \text{ if } r \text{ is even, or 0 if } r \text{ is odd.}$$

7. If the characteristic of F is 2, then the number of orthogonal matrices of order n over F is equal to

$$q^{\frac{n-1}{2}} \prod_{j=0}^{\frac{n-3}{2}} (q^{n-1}-q^{2j}), \text{ if } n \text{ is odd,}$$

or

$$q^{\frac{n}{2}} \prod_{j=1}^{\frac{n-2}{2}} (q^{n}-q^{2j}), \text{ if } n \text{ is even.}$$

8. If the characteristic of F is odd, then the number of orthogonal matrices of order n over F is equal to

$$2q^{\frac{n-1}{2}} \prod_{j=0}^{\frac{n-3}{2}} (q^{n-1}-q^{2j}), \text{ if } n \text{ is odd,}$$

$$2(q^{\frac{n}{2}}-1) \prod_{j=1}^{\frac{n-2}{2}} (q^{n}-q^{2j}), \text{ if } n \text{ is even and } -1 \text{ is a square in } F,$$

or

$$2(q^{\frac{n}{2}}+(-1)^{\frac{n+2}{2}}) \prod_{j=1}^{\frac{n-2}{2}} (q^{n}-q^{2j}), \text{ if } n \text{ is even and } -1 \text{ is not a square in } F.$$

9. A formula for $\phi(f(x))$, $f(x) \in F[x]$, is given by

$$\phi(f(x)) = q^{\deg f(x)} \prod_{p(x)|f(x)} \left(1 - \frac{1}{q^{\deg p(x)}}\right),$$

where $p(x)$ runs through all irreducible monic divisors of $f(x)$ over F.

10. The number of nonderogatory matrices of order n over F is equal to

$$g_n \sum_{deg(f(x))=n} \frac{1}{\phi(f(x))},$$

where the sum is over all monic polynomials $f(x)$ of degree n over F, and g_n is the number of nonsingular matrices of order n over F.

11. The number of similarity classes in $F^{n\times n}$ is equal to
$$\sum_{k_1+2k_2+\cdots+nk_n=n} q^{k_1+k_2+\cdots+k_n}.$$
where the sum is over all nonnegative n-tuples $(k_1, k_2, \cdots, k_n)$ with the property that $k_1 + 2k_2 + \cdots + nk_n = n$.
12. Let $f(x) = p_1(x)^{n_1}p_2(x)^{n_2}\ldots p_k(x)^{n_k}$, where $n_i \geq 1$ and $p_i(x)$ are distinct irreducible monic polynomials over F. The number of similarity classes in $F^{n\times n}$ of matrices with characteristic polynomial $f(x)$ is equal to $\pi(n_1)\pi(n_2)\ldots\pi(n_k)$, where $\pi(m)$ is the number of unrestricted partitions of m as a sum of positive integers.
13. The number of similarity classes in $F^{n\times n}$ of matrices with minimum polynomial of degree m is equal to
$$q^m \sum_{k_1+2k_2+\cdots mk_m=n-m} 1,$$
where the sum is over all nonnegative m-tuples $(k_1, k_2, \cdots, k_m)$ with the property that $k_1 + 2k_2 + \cdots + mk_m = n - m$.

Examples:

We illustrate each of the above facts in the correspondingly numbered example below. Unless stated otherwise, we assume that $F = GF(2)$.

1. The number of matrices of order 2 over F that map $\begin{bmatrix}1\\1\end{bmatrix}$ to itself is equal to $2^2 = 4$. These are
$$I_2, \begin{bmatrix}0&1\\1&0\end{bmatrix}, \begin{bmatrix}1&0\\1&0\end{bmatrix}, \text{ and } \begin{bmatrix}0&1\\0&1\end{bmatrix}.$$
2. The number of nonsingular matrices of order 2 over F that map $\begin{bmatrix}1\\1\end{bmatrix}$ to itself is equal to $2^2 - 2 = 2$. These are
$$I_2 \text{ and } \begin{bmatrix}0&1\\1&0\end{bmatrix}.$$
3. The number of nonsingular matrices of order 2 over F is equal to $(2^2-1)(2^2-2) = 6$. These are
$$I_2, \begin{bmatrix}1&1\\0&1\end{bmatrix}, \begin{bmatrix}0&1\\1&0\end{bmatrix}, \begin{bmatrix}0&1\\1&1\end{bmatrix} \begin{bmatrix}1&1\\1&0\end{bmatrix}, \text{ and } \begin{bmatrix}1&0\\1&1\end{bmatrix}.$$
4. The number of matrices of order 2 over F with rank 1 is equal to $\frac{(2^2-1)(2^2-1)}{(2-1)} = 9$. These are all the matrices in $F^{2\times 2}$, except the zero matrix and those listed in the previous example.
5. The number of symmetric matrices of order 2 over F with rank 1 is equal to $2^2 - 1 = 3$. These are
$$\begin{bmatrix}1&0\\0&0\end{bmatrix}, \begin{bmatrix}0&0\\0&1\end{bmatrix}, \text{ and } \begin{bmatrix}1&1\\1&1\end{bmatrix}.$$
6. The number of symmetric matrices of order 2 over F with zero diagonal and rank 2 is equal to $\frac{1}{2^2-1}(2^2 - 1)(2 - 1) = 1$, namely $\begin{bmatrix}0&1\\1&0\end{bmatrix}$.
7. The number of orthogonal matrices of order 2 over F is equal to 2. These are I_2 and $\begin{bmatrix}0&1\\1&0\end{bmatrix}$.
8. *Orthogonal matrices over* $GF(3)$ *and* $GF(9)$.

• The number of orthogonal matrices of order 2 over $F = GF(3)$ is equal to $2(3+(-1)^2) = 8$, since -1 is not a square in $GF(3)$. These are

$$\pm I_2, \pm \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \pm \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \pm \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}.$$

• The polynomial $x^2 + 1$ has a root in $F = GF(9)$, which we denote by i. Then $GF(9) = \{a + bi : a, b \in \mathrm{GF}(3)\}$. The number of orthogonal matrices of order 2 over $F = GF(9)$ is equal to $2(9 - 1) = 16$, since -1 is a square in $GF(9)$. These are the matrices listed under the previous bullet, including

$$\pm i \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}, \pm i \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}, \pm i \begin{bmatrix} -1 & 1 \\ 1 & 1 \end{bmatrix}, \text{ and } \pm i \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}.$$

9. For the monic polynomials of degree two over F, it follows that
   - $\phi(x^2 + x + 1) = 3$, since the only irreducible monic divisor of $x^2 + x + 1$ over F is itself;
   - $\phi(x^2 + 1) = 2$, since the only irreducible monic divisor of $x^2 + 1$ over F is $x + 1$;
   - $\phi(x^2) = 2$, since the only irreducible monic divisor of x^2 over F is x;
   - $\phi(x^2 + x) = 1$, since the irreducible monic divisors of $x^2 + x$ over F are x and $x + 1$.
10. From the previous example, we conclude that the number of nonderogatory matrices of order 2 over F is equal to

$$g_2 \left(\frac{1}{\phi(x^2 + x + 1)} + \frac{1}{\phi(x^2 + 1)} + \frac{1}{\phi(x^2)} + \frac{1}{\phi(x^2 + x)} \right) = 6 \left(\frac{1}{3} + \frac{1}{2} + \frac{1}{2} + \frac{1}{1} \right) = 14$$

($g_2 = 6$, according to Example 3). In the case of matrices of order 2, it follows that two matrices are similar if and only if they have the same minimum polynomial. Using this fact, it follows that the similarity classes of matrices of order 2 over F are

$$\mathcal{S}(x) = \{0_{2\times 2}\};\ \mathcal{S}(x + 1) = \{I_2\};\ \mathcal{S}(x^2 + x + 1) = \left\{ \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \right\};$$

$$\mathcal{S}(x^2 + 1) = \left\{ \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \right\};\ \mathcal{S}(x^2) = \left\{ \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \right\};$$

$$\mathcal{S}(x^2 + x) = \left\{ \begin{bmatrix} 0 & 0 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix}; \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \right\},$$

where $\mathcal{S}(f(x))$ denotes the similarity class associated with the minimum polynomial $f(x)$. All the classes except $\mathcal{S}(x)$ and $\mathcal{S}(x + 1)$ consist of nonderogatory matrices, hence the nonderogatory matrices add up to 14, as determined above.
11. The number of similarity classes of matrices of order 2 over F is equal to $2^{0+1} + 2^{2+0} = 6$. These are the classes listed in Example 10.
12. The number of similarity classes of matrices of order 2 over F with characteristic polynomial $x^2 + 1$ is 2, since $x^2 + 1 = (x + 1)^2$ and $\pi(2) = 2$. These are the classes $\mathcal{S}(x + 1)$ and $\mathcal{S}(x^2 + 1)$ in Example 10.
13. • The number of similarity classes of matrices of order 2 over F with minimum polynomial of degree 2 is equal to $2^2(\sum_{k_1+2k_2=0} 1) = 4$. These are the last four classes listed in Example 10.

   • The number of similarity classes of matrices of order 3 over F with minimum polynomial of degree 2 is equal to $2^2(\sum_{k_1+2k_2=1} 1) = 4$. Representatives for these classes are $C(x) \oplus C(x^2)$; $C(x + 1) \oplus C(x^2 + 1)$; $C(x) \oplus C(x^2 + x)$; and $C(x + 1) \oplus C(x^2 + x)$, respectively, where $C(f(x))$ denotes the companion matrix associated with the monic polynomial $f(x)$.

   • The number of similarity classes of matrices of order 4 over F with minimum polynomial of degree 2 is equal to $2^2(\sum_{k_1+2k_2=2} 1) = 8$. Representatives for these classes are $C(x) \oplus$

$C(x) \oplus C(x^2)$; $C(x^2) \oplus C(x^2)$; $C(x+1) \oplus C(x+1) \oplus C(x^2+1)$; $C(x^2+1) \oplus C(x^2+1)$; $C(x) \oplus C(x) \oplus C(x^2+x)$; $C(x+1) \oplus C(x+1) \oplus C(x^2+x)$; $C(x^2+x) \oplus C(x^2+x)$; and $C(x^2+x+1) \oplus C(x^2+x+1)$, respectively, where $C(f(x))$ denotes the companion matrix associated with the monic polynomial $f(x)$.

31.2 Factorization of Matrices

The reader is referred to the survey papers [Hal91], [Laf91], and [Wu89] for further background on this topic, which deals with matrices that can be factored in such a way that each factor is of a certain prescibed type (which need not be the same for all factors). Some well-known factorizations are the LU factorization (two factors that are lower and upper triangular, respectively — see Section 1.6), the QR factorization (two factors of which the first is unitary and the second is upper triangular — see Section 5.5), and the singular value decomposition (three factors of which the first and third are unitary and the second diagonal with positive entries — see Section 5.6). In one of the first results of this kind, G. Frobenius [Fro10] showed that any square matrix over an arbitrary field can be expressed as a product of two symmetric matrices, one of which is nonsingular. See [Hal91] for a discussion of this rather surprising result, given the unsymmetric nature of some matrices. In this section, the focus is on factorizations for which the order of the field plays an important role, and which, for example, may cause the underlying theory to be more complicated in certain cases (see Fact 1) or the results to be somewhat different to what is otherwise the case (see Fact 2). Such behavior is not uncommon for fields of small order or for fields of characteristic 2.

Definitions:

Let F be a field.

The **general linear group** $\mathrm{GL}(n, F)$ is the group consisting of all invertible $n \times n$ matrices over F.

The **special linear group** $\mathrm{SL}(n, F)$ is the subgroup of $\mathrm{GL}(n, F)$ consisting of all $n \times n$ matrices with determinant 1.

A matrix $A \in \mathrm{SL}(n, F)$ is a **commutator** of $\mathrm{GL}(n, F)$ if it can be expressed as $A = BCB^{-1}C^{-1}$ for some $B, C \in \mathrm{GL}(n, F)$.

A matrix $A \in F^{n\times n}$ is **diagonalizable over** F if there exists an invertible matrix $B \in F^{n\times n}$ and a diagonal matrix $D \in F^{n\times n}$ such that $B^{-1}AB = D$. If F is clear from the context, we will simply say "A is diagonalizable," but it should be kept in mind that diagonalizability depends on the underlying field; for example, see Example 2.

Similarity will be denoted by $\approx$.

Facts:

1. *Matrices that are commutators.*
   (a) The determinant of a commutator is always 1.
   (b) If $A \approx B$ and A is a commutator, then B is a commutator.
   (c) [Tho61], [Tho62a], [Tho62b] Every matrix $A \in \mathrm{SL}(n, F)$, F an arbitrary field, is a commutator of $\mathrm{GL}(n, F)$, unless $|F| = 2$ and A is similar to $\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$.

   The proofs, which are based on the rational canonical form, depend heavily on the number of elements in F and break down when F has five or fewer elements. For $|F| = 4$ or 5, it is still possible to adapt the general methods, but for $|F| = 2$ and 3 they break down drastically and new methods have to be used.

   (d) There have been a number of attempts to simply the theory of commutators. [Laf91], [Sou86], and [GPR84] present simplified treatments but none of them have been able to cover the whole theory as their proofs are only valid for matrices whose order is small relative to the order of the underlying field. [Bot06] presents a treatment that is valid for all matrices if the underlying field has at least four elements.

2. *Products of diagonalizable matrices.*

   (a) [Bot98], [Bot99] Every $A \in F^{n\times n}$ is a product of two diagonalizable matrices if $|F| \geq 4$. (In the case of characteristic 2 fields, different methods have been used to obtain the result.)

   (b) [Bot98] Every $A \in GF(3)^{n\times n}$ is a product of three diagonalizable matrices. [Djo67], [HP71] If A is nonsingular, then it is a product of two diagonalizable matrices if and only if A is similar to A^{-1}.

   (c) [Bal78] Every $A \in GF(2)^{n\times n}$ is a product of k diagonalizable matrices if and only if $k \cdot \text{null}(A) \geq \text{rank}(I_n - A)$.

3. *Factorization of symmetric matrices.*
   Proofs of the following facts can be found in [SL80].

   (a) Every symmetric $A \in GF(2^k)^{n\times n}$ of rank r can be factored as $A = BB^T$, where B is an $n \times m$ matrix with minimal

$$m = \begin{cases} r, & \text{if } A \text{ has a nonzero diagonal element} \\ r+1, & \text{otherwise.} \end{cases}$$

   (b) Every symmetric $A \in GF(p^k)^{n\times n}$, p an odd prime, of rank r can be factored as $A = BB^T$, where B is an $n \times m$ matrix with minimal

$$m = \begin{cases} r, & \text{if } A \text{ has a nonzero principal minor of order } r \text{ which is a square in } F \\ r+1, & \text{otherwise.} \end{cases}$$

Examples:

1. *The commutators of* $\text{GL}(2, GF(2))$.
   Let $F = GF(2)$, the field of two elements.
   • $|F^{2\times 2}| = 2^4 = 16$.
   • $\text{GL}(2, F) = \{I_2, A_0, A_1, A_2, A_3, A_4\}$, where
   $A_0 = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, $A_1 = \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix}$, $A_2 = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}$, $A_3 = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$, and $A_4 = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}$.
   Note that here $\text{SL}(2, F) = \text{GL}(2, F)$.
   • $\text{GL}(2, F)$ has three similarity classes, namely,
   $\mathcal{C}_1 = \{I_2\}$, $\mathcal{C}_2 = \{A_1, A_4\}$ (since $A_1 = A_0^{-1}A_4A_0$), and
   $\mathcal{C}_3 = \{A_0, A_2, A_3\}$ (since $A_2 = A_3^{-1}A_0A_3$, $A_3 = A_2^{-1}A_0A_2$).
   • The set of commutators in $\text{GL}(2, F)$ is $\mathcal{C}_1 \cup \mathcal{C}_2$.
   Note that $A_1 = A_0A_2A_0^{-1}A_2^{-1}$ and $A_4 = A_0A_3A_0^{-1}A_3^{-1}$.
   • In general, the only matrices with determinant 1 that are not commutators are those in $\mathcal{C}_3$ (over $F = GF(2)$).

2. $A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \in \mathbb{R}^{2\times 2}$ is diagonalizable over $\mathbb{C}$ but not over $\mathbb{R}$, since it has two distinct eigenvalues in $\mathbb{C}$ which do not lie in $\mathbb{R}$.

3. *Products of diagonalizable matrices.*

   Let $A = \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix}$. We express A as a product of diagonalizable matrices as follows, where in each case the number of factors is minimal.

   - $A = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} -1 & -1 \\ 0 & 1 \end{bmatrix}$ over $GF(5)$. Note that A is not diagonalizable over $GF(5)$.
   - A is already diagonalizable over $GF(4)$, since it has two distinct eigenvalues in $GF(4)$.
   - $A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} -1 & -1 \\ 0 & 1 \end{bmatrix}$ over $GF(3)$. Note that A cannot be expressed as a product of two diagonalizable matrices, since $A^{-1} = \begin{bmatrix} -1 & 1 \\ 1 & 0 \end{bmatrix} \approx \begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}$, which is not similar to A.
   - A cannot be expressed as a product of diagonalizable matrices over $GF(2)$, since the only nonsingular diagonalizable matrices over $GF(2)$ are the identity matrices.

   Let $B = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$. We express B as a product of diagonalizable matrices as follows, where in each case the number of factors is minimal. Note that, since $B \neq 0$ is nilpotent, it is not diagonalizable over any field.

   - $B = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$ over $GF(5)$ and $GF(3)$.
   - $B = \begin{bmatrix} 0 & 1 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}$ over $GF(4)$.
   - $B = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}$ over $GF(2)$. Note that each factor is idempotent.

   B cannot be expressed as a product of less than 3 diagonalizable factors, since $\mathrm{null}(B) = 1$ and $\mathrm{rank}(I_3 - B) = 3$.

4. *Factorization of symmetric matrices.*

   Let $A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$. We can express A as a product $A = BB^T$ over fields of order at most 5 as follows, where in each case the number of columns in B is minimal.

   - $A = \begin{bmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 0 & 1 \\ 1 & 0 \end{bmatrix}$ over $GF(2)$ and $GF(4)$. Note that we need three columns for B, since A does not have a nonzero diagonal entry.
   - $A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 2 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ 1 & 1 \end{bmatrix}$ over $GF(3)$. Note that we need three columns for B, since $|A| = 2$, which is not a square in $GF(3)$.
   - $A = \begin{bmatrix} 2 & 4 \\ 4 & 2 \end{bmatrix} \begin{bmatrix} 2 & 4 \\ 4 & 2 \end{bmatrix}$ over $GF(5)$. Note that we need only two columns for B in this case, since $|A| = 4$, which is a square in $GF(5)$.

31.3 Matrix Fields

In this section, unless stated otherwise, F denotes a finite field with q elements, i.e., $F = GF(q)$, where $q = p^k$ for some positive integer k and prime p. The minimum polynomial of $A \in F^{n\times n}$ is denoted by $q_A(x)$.

Definitions:

If K is an extension field of a field F, then the dimension of K, considered as a vector space over F, is called the **degree of** K **over** F, and denoted $[K : F]$. If $[K : F] = n$ (finite), then K is a **finite extension of degree** n **over** F.

By a **matrix field over** F we mean a subset $M \subseteq F^{n\times n}, n \geq 1$, such that M forms a field under the normal operations of addition and multiplication in $F^{n\times n}$. We also refer to M as a **matrix subfield** of (the matrix ring) $F^{n\times n}$.

The **rank** of M is defined as the rank of the multiplicative identity of M.

Two matrix subfields M and M' of $F^{n\times n}$ are **similar** if there exists a nonsingular matrix $P \in F^{n\times n}$ such that the similarity operator $A \mapsto P^{-1}AP$ defines a ring isomorphism between M and M', i.e., $M' = \{P^{-1}AP : A \in M\}$.

A polynomial $f(x) \in F[x]$ of degree m over F is **primitive** if it is monic and has a root in the finite extension $GF(q^m)$ of F that generates the multiplicative group of $GF(q^m)$.

For $A \in F^{n\times n}$, let $F[A]$ denote the subring of $F^{n\times n}$ defined by $F[A] = \{f(A) : f \in F[x]\}$.

Facts:

Facts requiring proof for which no specific reference is given can be found in [Bea72a], [Bea72b], or [Wil73].

1. A primitive polynomial over F is irreducible, but the converse need not be true, i.e., an irreducible monic polynomial over F need not be primitive. See Example 1.
2. For $A \in F^{n\times n}$, it follows that $F[A] = \{f(A) : f \in F[x] \text{ and } \deg(f) < \deg(q_A)\}$. The multiplicative identity of $F[A]$ is I_n.
3. $F[A]$ is a matrix subfield of $F^{n\times n}$ if and only if $q_A(x)$ is irreducible over F. In particular, A must be nonsingular.
4. The characteristic of a matrix field over F is equal to the characteristic of F.
5. $F[I_n] = \{cI_n : c \in F\}$ is a matrix subfield of $F^{n\times n}$, with multiplicative identity I_n, and $F[I_n]$ is isomorphic to F.
6. The multiplicative identity of a subfield of $F^{n\times n}$ need not be equal to I_n. For example, $\{cI_{n-1} \oplus [0] : c \in F\}$ is a subfield of $F^{n\times n}$ with multiplicative identity $I_{n-1} \oplus 0$. Thus, the multiplicative inverses in a subfield of $F^{n\times n}$ need not be the same as the ordinary inverses in $F^{n\times n}$. If, however, a matrix subfield M of $F^{n\times n}$ contains a nonsingular matrix, then all the nonzero matrices in M are nonsingular, and the multiplicative identity in M is I_n. In this case, the inverses in M are the same as the ordinary inverses in $F^{n\times n}$.
7. The nonzero matrices in a matrix field are all of the same rank.
8. A matrix subfield M of $F^{n\times n}$ need not contain an isomorphic copy of F. But it always contains $\{aJ : a \in GF(p)\}$, where J denotes the multiplicative identity of M, which is the prime subfield of M, and isomorphic to $GF(p)$.
9. *Matrix fields over the prime field* $GF(p)$.
   If $F = GF(p)$ (i.e., $k = 1$), then $M \subseteq F^{n\times n}$ is a matrix subfield of $F^{n\times n}$ if and only if M is similar to $\{g(A) \oplus 0_{n-r} : g(x) \in F[x]\}$ for some matrix $A = C(f(x)) \oplus \cdots \oplus C(f(x)) \in F^{r\times r}$, where $C(f(x))$ is the companion matrix of an irreducible monic

polynomial $f(x) \in F[x]$. The rank of M is equal to r, and the degree of M over its prime subfield is $m = \deg(f(x))$. (Note that $m \mid r$. In particular, if the multiplicative identity J of M is nonsingular, then $J = I_n$, and $m \mid n$.)

10. *Matrix fields over an arbitrary finite field F.*
    $M \subseteq F^{n\times n}$ is a matrix subfield of $F^{n\times n}$ if and only if M is similar to $\{(A \oplus 0)^i : 1 \leq i \leq p^m - 1\} \cup \{0\}$ for some matrix $A \in F^{r\times r}$ which satisfies $f(A) = 0$, where $f(x)$ is a primitive polynomial of degree m over $GF(p)$. The rank of M is equal to r, and the degree of M over its prime subfield is $m = \deg(f(x))$.

Examples:

1. *An irreducible polynomial need not be primitive.*
   - $f(x) = x^4 + x + 1$ is irreducible over $F = GF(2)$. It is also primitive, since it does not divide $x^3 + 1$ or $x^5 + 1 = (x+1)(x^4 + x^3 + x^2 + x + 1)$; hence, each of its roots generates the multiplicative group of $GF(16)$.
   - $g(x) = x^4 + x^3 + x^2 + x + 1$ is irreducible over $F = GF(2)$ but not primitive, since it divides $x^5 + 1$; hence, each of its roots has multiplicative order 5 and therefore cannot generate the multiplicative group of $GF(16)$.
2. If $0 \neq J \in F^{n\times n}$ is an idempotent matrix, then $\{cJ : c \in F\}$ is a matrix subfield of $F^{n\times n}$ with multiplicative identity J.
3. Let $F = GF(2)$ and $A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} \in F^{3\times 3}$. Since $q_A(x) = (x+1)(x^2 + x + 1)$ is not irreducible over F, it follows that $F[A]$ is not a matrix subfield of $F^{3\times 3}$.
4. *To illustrate that the degree of a matrix field does not divide its rank in general.*
   Let $F = GF(4)$, where $GF(4) = \{0, 1, \alpha, \alpha^2\}$ with α a root of $x^2 + x + 1$, and let $A_1 = [\alpha] \oplus 0_{2\times 2}$ and $A_2 = \begin{bmatrix} \alpha & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}$. Note that $f(A_i) = 0, 1 \leq i \leq 2$, where $f(x) = x^2 + x + 1$. Since $f(x)$ is primitive over $GF(2)$, it follows that $M_i = \{0, A_i, A_i^2, A_i^3\}$ is a matrix subfield of $F^{3\times 3}$ of degree $m = 2$ over its prime subfield. In the first case, $r = \text{rank}(M_1) = 1 < m$, and in the second case, $r = \text{rank}(M_2) = 3 > m$. In both cases $m \nmid r$.
5. [War94] *Matrix representation of finite fields.*
   - Working with finite fields computationally, it may be convenient to use a matrix field representation thereof in which multiplication is done cyclically and addition via ordinary matrix addition (see Fact 10). The following are the simplest such representations of $GF(8)$ and $GF(9)$.
   - Recall that the n^{th} cyclotomic polynomial $c_n(x)$ is defined as the product $c_n(x) = \prod(x - \alpha)$ taken over all $\phi(n)$ primitive n^{th} roots α of unity, where $\phi(n)$ is the Euler ϕ-function. It follows that

$$c_n(x) = (x^n - 1) \Big/ \prod_{d\mid n,\ d<n} c_d(x).$$

   - *A matrix representation of $GF(8)$.*

$$\begin{aligned} c_7(x) &= (x^7 - 1) \Big/ (x - 1) \\ &= x^6 + x^5 + x^4 + x^3 + x^2 + x + 1 \\ &= (x^3 + x + 1)(x^3 + x^2 + 1). \end{aligned}$$

Since both $x^3 + x + 1$ and $x^3 + x^2 + 1$ are irreducible of degree 3 over $GF(2)$ and are factors of $c_7(x)$, they are primitive, and therefore their companion matrices generate matrix fields

$\{A^i : 1 \leq i \leq 7\} \cup \{0\}$ of order 8, where

$$A = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \text{ or } \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 1 \end{bmatrix}.$$

- *A matrix representation of* $GF(9)$.

$$c_8(x) = (x^8 - 1) \Big/ (x^4 - 1) = x^4 + 1$$

The monic irreducible quadratics over $GF(3)$ are $x^2 + 1$, $x^2 - x - 1$, and $x^2 + x - 1$. The desired factorization is

$$c_8(x) = x^4 + 1 = (x^2 - x - 1)(x^2 + x - 1);$$

hence, the companion matrices associated with $x^2 - x - 1$ and $x^2 + x - 1$ generate matrix fields $\{A^i : 1 \leq i \leq 8\} \cup \{0\}$ of order 9, where

$$A = \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix} \text{ or } \begin{bmatrix} 0 & 1 \\ 1 & 2 \end{bmatrix}.$$

Note that the companion matrix associated with $x^2 + 1$ does not generate a field of order 9, since although it is irreducible over $GF(3)$, it is not primitive (no root generates the multiplicative group of $GF(9)$).

6. [Wil73] *A matrix representation of* $GF(4)$ *in a fixed matrix ring.*
The following is a construction of a field of order 4 in $F^{n \times n}$, where $F = GF(16)$ and $n \geq 1$.

$$\begin{aligned} c_{15}(x) &= (x^{15} - 1) \Big/ (x^5 - 1)(x^2 + x + 1)) \\ &= (x^{10} + x^5 + 1) \Big/ (x^2 + x + 1)) \\ &= x^8 + x^7 + x^5 + x^4 + x^3 + x + 1 \\ &= (x^4 + x^3 + 1)(x^4 + x + 1). \end{aligned}$$

Hence, $g(x) = x^4 + x^3 + 1$ is primitive over $GF(2)$, and therefore $GF(16) = \{\alpha^i : 1 \leq i \leq 15\} \cup \{0\}$, where α is a root of $g(x)$. Since $f(x) = x^2 + x + 1$ is primitive over $GF(2)$ and $f(x) = (x - \alpha^5)(x - \alpha^{10})$, it follows that $A = \alpha^5 I_{n_1} \oplus \alpha^{10} I_{n_2} \oplus 0_{n_3}$ satisfies $f(A) = 0$, where n_1, n_2, and n_3 are nonnegative integers such that $n = n_1 + n_2 + n_3$ and $n_1 + n_2 > 0$. Therefore, any matrix similar to A over F generates the multiplicative group of a field of order 4 in $F^{n \times n}$.

31.4 Congruence

For the respective treatment of congruence and *congruence of Hermitian matrices over the real and complex fields, and the associated invariants given by the inertia of these matrices, the reader is referred to Section 9.3. See also Chapter 13 for various congruence results associated with the matrix representations of these forms.

Definitions:

Let F be a field.

A matrix $A \in F^{n \times n}$ is **congruent** to a matrix $B \in F^{n \times n}$ if there exists a nonsingular matrix $C \in F^{n \times n}$ such that $A = C^T BC$.

A matrix $A \in F^{n \times n}$ is **alternating** if $a_{ii} = 0,\ i = 1, 2, \ldots, n$ and $a_{ji} = -a_{ij},\ 1 \leq i < j \leq n$.

A matrix $A \in F^{n\times n}$ is **skew-symmetric** if $A^T = -A$.

Facts:

1. *Alternating matrices.* See also Section 13.3, which discusses, among others, the canonical representation of alternating bilinear forms on finite dimensional vector spaces.
   (a) $A \in F^{n\times n}$ is alternating if and only $\mathbf{x}^T A\mathbf{x} = 0$ for all $\mathbf{x} \in F^n$.
   (b) If the characteristic of F is not 2, then $A \in F^{n\times n}$ is alternating if and only if it is skew-symmetric.
   (c) If the characteristic of F is 2, then $A \in F^{n\times n}$ is alternating if and only if it is symmetric with zero diagonal.
2. *Matrices congruent to a diagonal matrix.* See also Section 13.2.
   Proofs of the following facts can be found in [Alb38] . A matrix that is congruent to a diagonal matrix is clearly symmetric. For the converse, we have:
   (a) Every symmetric matrix over a field with characteristic not equal to 2 is congruent to a diagonal matrix.
   (b) A symmetric matrix over a field with characteristic 2 is congruent to a diagonal matrix if and only if it has a nonzero diagonal entry.
3. *Matrices congruent to $I_r \oplus 0_{n-r}$.*
   Let $\operatorname{rank}(A) = r$.
   (a) [Dic58, Sect. 169], [SL80] A symmetric matrix $A \in F^{n\times n}$ over a finite field F with characteristic not equal to 2 is congruent to $I_r \oplus 0_{n-r}$ if and only if A has a nonzero principal minor of order r which is a square in F. In particular, a nonsingular symmetric matrix A is congruent to I_n if and only if $|A|$ is a square in F.
   (b) [Alb38] A symmetric matrix $A \in F^{n\times n}$ over a finite field F with characteristic 2 is congruent to $I_r \oplus 0_{n-r}$ if and only if A has a nonzero diagonal entry.
4. *Matrices congruent to a triangular matrix.*
   (a) [Bal68] A nonzero matrix $A \in F^{n\times n}$ over a field F with at least three elements is congruent to a triangular matrix if and only if it is not alternating.
   (b) [Bot97] An $n \times n$ matrix A of rank r over $GF(2)$ is congruent to a triangular matrix if and only if A is not congruent to one of the following matrices:

$$\text{(i)}\quad \left(\oplus_{r/2}\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}\right) \oplus O_{n-r} \qquad (r \geq 2 \text{ and even})$$

$$\text{(ii)}\quad \begin{bmatrix} & I_{r-2} & & \vdots & 0 & \\ \cdots & \cdots & \cdots & \vdots & \cdots & \\ 0 & \cdots & 0 & \vdots & 0 & 1 \\ 1 & \cdots & 1 & \vdots & 1 & 0 \end{bmatrix} \oplus O_{n-r} \qquad (r \geq 3, r \text{ even or odd})$$

$$\text{(iii)}\quad \begin{bmatrix} & & I_{r-2} & & \vdots & 0 & \\ \cdots & \cdots & \cdots & \cdots & \vdots & \cdots & \\ 1 & 0 & \cdots & 0 & \vdots & 0 & 1 \\ 0 & 1 & \cdots & 1 & \vdots & 1 & 0 \end{bmatrix} \oplus O_{n-r} \qquad (r \geq 4, r \text{ even or odd})$$

$$\text{(iv)} \quad \begin{bmatrix} & & I_{r-2} & & & \vdots & 0 & \\ \cdots & \cdots & \cdots & \cdots & \cdots & \vdots & \cdots & \\ 1 & 1 & 0 & \ldots & 0 & \vdots & 0 & 1 \\ 0 & 0 & 1 & \ldots & 1 & \vdots & 1 & 0 \end{bmatrix} \oplus O_{n-r} \quad (r \geq 6 \text{ and even}).$$

Examples:

1. $A = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}$ over $GF(3)$ is congruent to I_2, since it is symmetric and $\det(A) = 1$.
   - $A = B^T I_2 B$, where $B = \begin{bmatrix} -1 & -1 \\ -1 & 1 \end{bmatrix}$.
2. $A = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}$ over $GF(3)$ is not congruent to I_2, since $\det(A) = -1$, which is not a square in $GF(3)$.
   - For suppose $A = C^T I_2 C = C^T C$, then $\det(A) = \det(C)^2 = -1$, which is a contradiction.
3. Note that $GF(4) = \{0, 1, \alpha, \alpha + 1\}$, where $\alpha^2 = \alpha + 1$. The matrix $A = \begin{bmatrix} 1+\alpha & \alpha \\ \alpha & 0 \end{bmatrix}$ over $GF(4)$ is congruent to I_2, since it is symmetric with a nonzero diagonal entry.
   - $A = B^T I_2 B$, where $B = \begin{bmatrix} \alpha & 1 \\ 0 & 1 \end{bmatrix}$.
4. $A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}$ is not triangulable over $F = GF(2)$.
   - The diagonal elements of a nonsingular triangular matrix $T \in F^{3\times 3}$ must all be 1. Therefore, F^3 has a basis (the standard basis, for example) consisting of unit vectors ($\mathbf{x}^T T \mathbf{x} = 1$) with respect to the bilinear form associated with T .
   - $\mathbf{x}^T A \mathbf{x} = 1 \Leftrightarrow x_1^2 + x_1 x_3 = 1 \Leftrightarrow x_1(x_1 + x_3) = 1 \Leftrightarrow x_1 = 1$ and $x_3 = 0$. Therefore, all unit vectors associated with A lie in a two-dimensional subspace of F^3. Thus, A cannot be congruent to T.

31.5 Generalized Inverses

See also Chapter 27 for a detailed discussion of generalized inverses over the complex field.

Definitions:

Let F be a field and let $- : a \mapsto \bar{a}$ denote an involutory field automorphism of F (i.e., an automorphism such that $\bar{\bar{a}} = a$).

For $A \in F^{m\times n}$, let $A^* = \bar{A}^T$, where $\bar{A} = (\bar{a}_{ij})$.

A is **Hermitian** if $A = A^*$.

The following four types of generalized inverses are identified:

(i) $A^{\hat{i}} \in F^{n\times m}$ is an **inner inverse** (sometimes also referred to as a **generalized inverse**) of A if $AA^{\hat{i}}A = A$;

(ii) $A^{\hat{r}} \in F^{n\times m}$ is a **reflexive generalized inverse** of A if $AA^{\hat{r}}A = A$ and $A^{\hat{r}}AA^{\hat{r}} = A^{\hat{r}}$;

(iii) $A^{\hat{n}} \in F^{n\times m}$ is a **normalized generalized inverse** of A if $AA^{\hat{n}}A = A$, $A^{\hat{n}}AA^{\hat{n}} = A^{\hat{n}}$, and $(AA^{\hat{n}})^* = AA^{\hat{n}}$; and

(iv) $A^\dagger \in F^{n\times m}$ is a **(Moore-Penrose) pseudoinverse** of A if $AA^\dagger A = A$, $A^\dagger AA^\dagger = A^\dagger$, $(AA^\dagger)^* = AA^\dagger$, and $(A^\dagger A)^* = A^\dagger A$.

Facts:

Proofs of the following facts can be found in [Pea68], [Ful78], or [Ful79].

1. Every matrix over an arbitrary field has a reflexive generalized inverse.
2. A matrix $A \in F^{m\times n}$ over an arbitrary field F, with involutory field automorphism $- : a \mapsto \bar{a}$, has a normalized generalized inverse if and only if $\operatorname{rank}(A^*A) = \operatorname{rank}(A)$.
3. A matrix $A \in F^{m\times n}$ over an arbitrary field F, with involutory field automorphism $- : a \mapsto \bar{a}$, has a pseudoinverse if and only if $\operatorname{rank}(A^*A) = \operatorname{rank}(AA^*) = \operatorname{rank}(A)$.
4. A reflexive generalized inverse of a matrix, as well as a normalized generalized inverse, if they exist, need not be unique, but a pseudoinverse, if it exists, is always unique.
5. Let $q = p^k$, where p is an odd prime and $k \geq 1$ is an integer. The mapping $- : GF(q^2) \to GF(q^2)$ defined by $\bar{a} = a^q$ is an involutory automorphism of $GF(q^2)$ with fixed field $GF(q)$. Let $w = g^{(q+1)/2}$, where g is a generator of the multiplicative group of $GF(q^2)$. Then $GF(q^2) = \{a + bw : a, b \in GF(q\})$, and $\overline{a + bw} = a - bw$.
6. A matrix $A \in GF(q^2)^{m\times n}$, with $\operatorname{rank}(A) = r$, and $- : a \mapsto \bar{a}$ and q as in Fact 5, has a normalized generalized inverse if and only if $A = RS$, with $R : m \times r$, $S : r \times n$, and $R^*R = I_r$. It has a pseudoinverse if and only if $A = RQS$, with $R : m \times r$, $Q : r \times r$ nonsingular, $S : r \times n$, and $R^*R = SS^* = I_r$.
7. If F is a finite field with characteristic 2 and $- : a \mapsto \bar{a}$ is any involutory automorphism of F which is not the identity, then the same results as in Fact 6 hold for matrices over F.
8. Let F be a finite field with characteristic 2 and let $- : a \mapsto \bar{a}$ be the identity automorphism of F. Then $A^* = A^T$ for all $A \in F^{m\times n}$. Let $\operatorname{rank}(A) = r$. Then A has a normalized generalized inverse if and only if $A = RS$, with $R : m \times r$, $S : r \times n$, and $R^TR = I_r$ or $R^TR = \begin{bmatrix} 0 & I_k \\ I_k & 0 \end{bmatrix}$ $(r = 2k)$. It has a pseudoinverse if and only if $A = RQS$, with $R : m \times r$, $Q : r \times r$ nonsingular, $S : r \times n$, $R^TR = I_r$ or $R^TR = \begin{bmatrix} 0 & I_k \\ I_k & 0 \end{bmatrix}$ $(r = 2k)$, and $SS^T = I_r$ or $SS^T = \begin{bmatrix} 0 & I_k \\ I_k & 0 \end{bmatrix}$ $(r = 2k)$.

Examples:

1. *Generalized inverses over* $GF(9)$.

   • The polynomial $x^2 + 1$ is irreducible over $GF(3)$. Let i denote a root of $x^2 + 1$ in $GF(9)$. Then $i^2 = -1$, and $GF(9) = \{a + bi : a, b \in GF(3)\}$. In what follows, $- : GF(9) \to GF(9)$ will denote the involutory automorphism defined by $- : a + bi \mapsto (a + bi)^3 = a - bi$.

   • Reflexive generalized inverses of $A = \begin{bmatrix} 1 & -1+i \\ 1+i & 1 \end{bmatrix}$ over $GF(9)$ are, for example, $A^{\hat{r}} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$, $\begin{bmatrix} -1-i & 0 \\ 1 & 0 \end{bmatrix}$ and $\begin{bmatrix} -i & 1 \\ 0 & 0 \end{bmatrix}$. In fact, since

   $$A = \begin{bmatrix} 1 & 0 \\ 1+i & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & -1+i \\ 0 & 1 \end{bmatrix},$$

   it follows that all reflexive generalized inverses of A are given by

   $$A^{\hat{r}} = \begin{bmatrix} 1 & -1+i \\ 0 & 1 \end{bmatrix}^{-1} \begin{bmatrix} 1 & b \\ c & cb \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 1+i & 1 \end{bmatrix}^{-1} = \begin{bmatrix} 1 & 1-i \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & b \\ c & cb \end{bmatrix} \begin{bmatrix} 1 & 0 \\ -1-i & 1 \end{bmatrix},$$

   where b and c are arbitrary elements of $GF(9)$. A does not have a normalized generalized inverse, since $A^*A = 0$, hence $\operatorname{rank}(A^*A) \neq \operatorname{rank}(A)$.

- The matrix $A = \begin{bmatrix} 1+i & -1 \\ 1+i & -1 \end{bmatrix}$ over $GF(9)$ has at least one normalized generalized inverse, since rank(A^*A) =rank(A) $=$ 1. Examples of such inverses are $A^{\hat{n}} = \begin{bmatrix} 1-i & 1-i \\ 0 & 0 \end{bmatrix}$ and $\begin{bmatrix} 1+i & 1+i \\ 1-i & 1-i \end{bmatrix}$. Since $A = \begin{bmatrix} 1+i & 0 \\ 1+i & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 1-i \\ 0 & 1 \end{bmatrix}$, the reflexive generalized inverses of A are given by

$$A^{\hat{r}} = \begin{bmatrix} 1 & 1-i \\ 0 & 1 \end{bmatrix}^{-1} \begin{bmatrix} 1 & b \\ c & cb \end{bmatrix} \begin{bmatrix} 1+i & 0 \\ 1+i & 1 \end{bmatrix}^{-1} = \begin{bmatrix} 1 & -1+i \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & b \\ c & cb \end{bmatrix} \begin{bmatrix} -1+i & 0 \\ -1 & 1 \end{bmatrix},$$

where b and c are arbitrary elements of $GF(9)$. It follows that $AA^{\hat{r}}$ is Hermitian if and only if $b = 1-i$, hence all the normalized generalized inverses of A are given by

$$A^{\hat{n}} = \begin{bmatrix} 1 & -1+i \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1-i \\ c & c(1-i) \end{bmatrix} \begin{bmatrix} -1+i & 0 \\ -1 & 1 \end{bmatrix},$$

where c is an arbitrary element of $GF(9)$. A does not have a pseudoinverse, since $AA^* = 0$, hence rank(A^*A) $\neq$rank(A).

- The matrix $A = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$ over $GF(9)$ has a (unique) pseudoinverse, since rank(A) $=$ rank(A^*A) $=$ rank(AA^*) $= 1$. Since $A^2 = -A$, it follows that $A^\dagger = A$

Matrices over Integral Domains

Shmuel Friedland
University of Illinois at Chicago

32.1 Certain Integral Domains 32-1
32.2 Equivalence of Matrices 32-5
32.3 Linear Equations over Bezout Domains 32-8
32.4 Strict Equivalence of Pencils 32-10
References 32-11

In this chapter, we present some results on matrices over integral domains, which extend the well-known results for matrices over the fields discussed in Chapter 1 of this book. The general theory of linear algebra over commutative rings is extensively studied in the book [McD84]. It is mostly intended for readers with a thorough training in ring theory. The aim of this chapter is to give a brief survey of notions and facts about matrices over classical domains that come up in applications, namely over the ring of integers, the ring of polynomials over the field, the ring of analytic functions in one variable on an open connected set, and germs of analytic functions in one variable at the origin. The last section of this chapter is devoted to the notion of strict equivalence of pencils.

Most of the results in this chapter are well known to the experts. A few new results are taken from the book in progress [Fri], which are mostly contained in the preprint [Fri81].

32.1 Certain Integral Domains

Definitions:

A commutative ring without zero divisors and containing identity 1 is an **integral domain** and denoted by $\mathbb{D}$.

The **quotient field** F of a given integral domain $\mathbb{D}$ is formed by the set of equivalence classes of all quotients $\frac{a}{b}, b \neq 0$, where $\frac{a}{b} \equiv \frac{c}{d}$ if and only if $ad = bc$, such that

$$\frac{a}{b} + \frac{c}{d} = \frac{ad+bc}{bd}, \quad \frac{a}{b}\frac{c}{d} = \frac{ac}{bd}, \quad b, d \neq 0.$$

For $\mathbf{x} = [x_1, \ldots, x_n]^T \in \mathbb{D}^n, \alpha = [\alpha_1, \ldots, \alpha_n]^T \in \mathbb{Z}_+^n$ we define $\mathbf{x}^\alpha = x_1^{\alpha_1} \cdots x_n^{\alpha_n}$ and $|\alpha| = \sum_{i=1}^n |\alpha_i|$.

$\mathbb{D}[\mathbf{x}] = \mathbb{D}[x_1, \ldots, x_n]$ is the ring of all **polynomials** $p(\mathbf{x}) = p(x_1, \ldots, x_n)$ in n variables with coefficients in $\mathbb{D}$:

$$p(x) = \sum_{|\alpha| \leq m} a_\alpha x^\alpha.$$

The **total degree**, or simply the **degree** of $p(\mathbf{x}) \neq 0$, denoted by deg p, is the maximum $m \in \mathbb{Z}_+$ such that there exists $a_\alpha \neq 0$ such that $|\alpha| = m$. (deg $0 = -\infty$.)

A polynomial p is **homogeneous** if $a_\alpha = 0$ for all $|\alpha| < \deg p$.

A polynomial $p(x) = \sum_{i=0}^{n} a_i x^i \in \mathbb{D}[x]$ is **monic** if $a_n = 1$.

$F(\mathbf{x})$ denotes the quotient field of $F[\mathbf{x}]$, and is the **field of rational functions** over F in n variables.

Let $\Omega \subset \mathbb{C}^n$ be a nonempty path-connected set. Then $\mathrm{H}(\Omega)$ denotes the ring of analytic functions $f(\mathbf{z})$, such that for each $\zeta \in \Omega$ there exists an open neighborhood $O(\zeta, f)$ of ζ such that f is analytic on $O(f, \zeta)$. The addition and the product of functions are given by the standard identities: $(f+g)(\zeta) = f(\zeta) + g(\zeta), (fg)(\zeta) = f(\zeta)g(\zeta)$. If Ω is an open set, we assume that f is defined only on Ω. If Ω consists of one point ζ, then H_ζ stands for $\mathrm{H}(\{\zeta\})$.

Denote by $\mathcal{M}(\Omega), \mathcal{M}_\zeta$ the quotient fields of $\mathrm{H}(\Omega), \mathrm{H}_\zeta$, respectively.

For $a, d \in \mathbb{D}$, d **divides** a (or d is a **divisor** of a), denoted by $d|a$, if $a = db$ for some $b \in \mathbb{D}$.

$a \in \mathbb{D}$ is **unit** if $a|1$.

$a, b \in \mathbb{D}$ are **associates**, denoted by $a \equiv b$, if $a|b$ and $b|a$. Denote $\{\{a\}\} = \{b \in \mathbb{D} : \ b \equiv a\}$.

The associates of $a \in \mathbb{D}$ and the units are called **improper** divisors of a.

$a \in \mathbb{D}$ is **irreducible** if it is not a unit and every divisor of a is improper.

A nonzero, nonunit element $p \in \mathbb{D}$ is **prime** if for any $a, b \in \mathbb{D}, p|ab$ implies $p|a$ or $p|b$.

Let $a_1, \ldots, a_n \in \mathbb{D}$. Assume first that not all of $a_1, \ldots, a_n$ are equal to zero. An element $d \in \mathbb{D}$ is a **greatest common divisor** (g.c.d) of $a_1, \ldots, a_n$ if $d|a_i$ for $i = 1, \ldots, n$, and for any d' such that $d'|a_i, i = 1, \ldots, n$, $d'|d$. Denote by $(a_1, \ldots, a_n)$ any g.c.d. of $a_1, \ldots, a_n$. Then $\{\{(a_1, \ldots, a_n)\}\}$ is the equivalence class of all g.c.d. of $a_1, \ldots, a_n$. For $a_1 = \ldots = a_n = 0$, we define 0 to be the g.c.d. of $a_1, \ldots, a_n$, i.e. $(a_1, \ldots, a_n) = 0$.

$a_1, \ldots, a_n \in \mathbb{D}$ are **coprime** if $\{\{(a_1, \ldots, a_n)\}\} = \{\{1\}\}$.

$I \subseteq \mathbb{D}$ is an **ideal** if for any $a, b \in I$ and $p, q \in \mathbb{D}$ the element $pa + qb$ belongs to I.

An ideal $I \neq \mathbb{D}$ is **prime** if $ab \in I$ implies that either a or b is in I.

An ideal $I \neq \mathbb{D}$ is **maximal** if the only ideals that contain I are I and $\mathbb{D}$.

An ideal I is **finitely generated** if there exists k elements (**generators**) $p_1, \ldots, p_k \in I$ such that any $i \in I$ is of the form $i = a_1 p_1 + \cdots + a_k p_k$ for some $a_1, \ldots, a_k \in \mathbb{D}$.

An ideal is **principal** ideal if it is generated by one element p.

$\mathbb{D}$ is a **greatest common divisor** domain (GCDD), denoted by $\mathbb{D}_g$, if any two elements in $\mathbb{D}$ have a g.c.d.

$\mathbb{D}$ is a **unique factorization** domain (UFD), denoted by $\mathbb{D}_u$, if any nonzero, nonunit element a can be factored as a product of irreducible elements $a = p_1 \cdots p_r$, and this factorization is unique within order and unit factors.

$\mathbb{D}$ is a **principal ideal** domain (PID), denoted $\mathbb{D}_p$, if any ideal of $\mathbb{D}$ is principal.

$\mathbb{D}$ is a **Euclidean** domain (ED), denoted $\mathbb{D}_e$, if there exists a function $d : \mathbb{D}\backslash\{0\} \to \mathbb{Z}_+$ such that:

$$\begin{aligned}
&\text{for all } a, b \in \mathbb{D},\ ab \neq 0, \quad d(a) \leq d(ab);\\
&\text{for any } a, b \in \mathbb{D},\ ab \neq 0,\ \text{there exists } t, r \in \mathbb{D} \text{ such that}\\
&a = tb + r,\ \text{where either } r = 0 \text{ or } d(r) < d(b).
\end{aligned}$$

It is convenient to define $d(0) = \infty$. Let $a_1, a_2 \in \mathbb{D}_e$ and assume that $\infty > d(a_1) \geq d(a_2)$. **Euclid's algorithm** consists of a sequence $a_1, \ldots, a_{k+1}$, where $(a_1 \ldots a_k) \neq 0$, which is defined recursively as follows:

$$a_i = t_i a_{i+1} + a_{i+2}, \quad a_{i+2} = 0 \text{ or } d(a_{i+2}) < d(a_{i+1}) \quad \text{for} \quad i = 1, \ldots k-1.$$

[Hel43], [Kap49] A GCDD $\mathbb{D}$ is an **elementary divisor** domain (EDD), denoted by $\mathbb{D}_{ed}$, if for any three elements $a, b, c \in \mathbb{D}$ there exists $p, q, x, y \in \mathbb{D}$ such that $(a, b, c) = (px)a + (py)b + (qy)c$.

A GCDD $\mathbb{D}$ is a **Bezout** domain (BD), denoted by $\mathbb{D}_b$, if for any two elements $a, b \in \mathbb{D}$ $(a, b) = pa + qb$, for some $p, q \in \mathbb{D}$.

$p(x) = \sum_{i=0}^{m} a_i x^{m-i} \in \mathbb{Z}[x], a_0 \neq 0, m \geq 1$ is **primitive** if 1 is a g.c.d. of $a_0, \ldots, a_m$.

For $m \in \mathbb{N}$, the set of integers modulo m is denoted by $\mathbb{Z}_m$.

Facts:

Most of the facts about domains can be found in [ZS58] and [DF04]. More special results and references on the elementary divisor domains and rings are in [McD84]. The standard results on the domains of analytic functions can be found in [GR65]. More special results on analytic functions in one complex variable are in [Rud74].

1. Any integral domain satisfies *cancellation laws*: if $ab = ac$ or $ba = ca$ and $a \neq 0$, then $b = c$.
2. An integral domain such that any nonzero element is unit is a field F, and any field is an integral domain in which any nonzero element is unit.
3. A finite integral domain is a field.
4. $\mathbb{D}[\mathbf{x}]$ is an integral domain.
5. $\mathrm{H}(\Omega)$ is an integral domain.
6. Any prime element in $\mathbb{D}$ is irreducible.
7. In a UFD, any irreducible element is prime. This is not true in all integral domains.
8. Let $\mathbb{D}$ be a UFD. Then $\mathbb{D}[x]$ is a UFD. Hence, $\mathbb{D}[\mathbf{x}]$ is a UFD.
9. Let $a_1, a_2 \in \mathbb{D}_e$ and assume that $\infty > d(a_1) \geq d(a_2)$. Then Euclid's algorithm terminates in a finite number of steps, i.e., there exists $k \geq 3$ such that $a_1 \neq 0, \ldots, a_k \neq 0$ and $a_{k+1} = 0$. Hence, $a_k = (a_1, a_2)$.
10. An ED is a PID.
11. A PID is an EDD.
12. A PID is a UFD.
13. An EDD is a BD.
14. A BD is a GCDD.
15. A UFD is a GCDD.
16. The converses of Facts 10, 11, 12, 14, and 15 are false (see Facts 28, 27, 21, and 22).
17. [DF04, Chap. 8] An integral domain that is both a BD and a UFD is a PID.
18. An integral domain is a Bezout domain if and only if any finitely generated ideal is principal.
19. $\mathbb{Z}$ is an ED with $d(a) = |a|$.
20. Let $p, q \in \mathbb{Z}[x]$ be primitive polynomials. Then pq is primitive.
21. $F[x]$ is an ED with $d(p) =$ the degree of a nonzero polynomial. Hence, $F[x_1, \ldots, x_n]$ is a UFD. But $F[x_1, \ldots, x_n]$ is not a PID for $n \geq 2$.
22. $\mathbb{Z}[x_1, \ldots, x_m]$, $F[x_1, \ldots, x_n]$, and $\mathrm{H}(\Omega)$ (for a connected set $\Omega \subset \mathbb{C}^n$) are GCDDs, but for $m \geq 1$ and $n \geq 2$ these domains are not BDs.
23. [Fri] (See Example 17.) Let $\Omega \subset \mathbb{C}$ be an open connected set. Then for $a, b \in \mathrm{H}(\Omega)$ there exists $p \in \mathrm{H}(\Omega)$ such that $(a, b) = pa + b$.
24. H_ζ, $\zeta \in \mathbb{C}$, is a UFD.
25. If $\Omega \subset \mathbb{C}^n$ is a connected open set, then $\mathrm{H}(\Omega)$ is not a UFD. (For $n = 1$ there is no prime factorization of an analytic function $f \in \mathrm{H}(\Omega)$ with an infinite countable number of zeros.)
26. Let $\Omega \subset \mathbb{C}$ be a compact connected set. Then $\mathrm{H}(\Omega)$ is an ED. Here, $d(a)$ is the number of zeros of a nonzero function $a \in \mathrm{H}(\Omega)$ counted with their multiplicities.
27. [Fri] If $\Omega \subset \mathbb{C}$ is an open connected set, then $\mathrm{H}(\Omega)$ is an EDD. (See Example 17.) As $\mathrm{H}(\Omega)$ is not a UFD, it follows that $\mathrm{H}(\Omega)$ is not a PID. (Contrary to [McD84, Exc. II.E.10 (b), p. 144].)
28. [DF04, Chap. 8] $\mathbb{Z}[(1 + \sqrt{-19})/2]$ is a PID that is not an ED.

Examples:

1. $\{1, -1\}$ is the set of units in $\mathbb{Z}$. A g.c.d. of $a_1, \ldots, a_k \in \mathbb{Z}$ is *uniquely normalized* by the condition $(a_1, \ldots, a_k) \geq 0$.
2. A positive integer $p \in \mathbb{Z}$ is irreducible if and only if p is prime.
3. $\mathbb{Z}_m$ is an integral domain and, hence, a field with m elements if and only if p is a prime.
4. $\mathbb{Z} \supset I$ is a prime ideal if and only if all elements of I are divisible by some prime p.
5. $\{1, -1\}$ is the set of units in $\mathbb{Z}[x]$. A g.c.d. of $p_1, \ldots, p_k \in \mathbb{Z}[x]$, is *uniquely normalized* by the condition $(p_1, \ldots, p_k) = \sum_{i=0}^{m} a_i x^{m-i}$ and $a_0 > 0$.
6. Any prime element in $p(x) \in \mathbb{Z}[x], \deg p \geq 1$, is a primitive polynomial.
7. Let $p(x) = 2x + 3, q(x) = 5x - 3 \in \mathbb{Z}[x]$. Clearly p, q are primitive polynomials and $(p(x), q(x)) = 1$. However, 1 cannot be expressed as $1 = a(x)p(x) + b(x)q(x)$, where $a(x), b(x) \in \mathbb{Z}[x]$. Indeed, if this was possible, then $1 = a(0)p(0) + b(0)q(0) = 3(a(0) - b(0))$, which is impossible for $a(0), b(0) \in \mathbb{Z}$. Hence, $\mathbb{Z}[x]$ is not BD.
8. The field of quotients of $\mathbb{Z}$ is the field of rational numbers $\mathbb{Q}$.
9. Let $p(x), q(x) \in \mathbb{Z}[x]$ be two nonzero polynomials. Let $(p(x), q(x))$ be the g.c.d of p, q in $\mathbb{Z}[x]$. Use the fact that $p(x), q(x) \in \mathbb{Q}[x]$ to deduce that there exists a positive integer m and $a(x), b(x) \in \mathbb{Z}[x]$ such that $a(x)p(x) + b(x)q(x) = m(p(x), q(x))$. Furthermore, if $c(x)p(x) + d(x)q(x) = l(p(x), q(x))$ for some $c(x), d(x) \in \mathbb{Z}[x]$ and $0 \neq l \in \mathbb{Z}$, then $m|l$.
10. The set of real numbers $\mathbb{R}$ and the set of complex numbers $\mathbb{C}$ are fields.
11. A g.c.d. of $a_1, \ldots, a_k \in F[x]$ is *uniquely normalized* by the condition $(p_1, \ldots, p_k)$ is a monic polynomial.
12. A linear polynomial in $\mathbb{D}[\mathbf{x}]$ is irreducible.
13. Let $\Omega \subset \mathbb{C}$ be a connected set. Then each irreducible element of $\mathrm{H}(\Omega)$ is an associate of $z - \zeta$ for some $\zeta \in \Omega$.
14. For $\zeta \in \mathbb{C}$ H_ζ, every irreducible element is of the form $a(z - \zeta)$ for some $0 \neq a \in \mathbb{C}$. A g.c.d. of $a_1, \ldots, a_k \in \mathrm{H}_\zeta$ is *uniquely normalized* by the condition $(a_1, \ldots, a_k) = (z - \zeta)^m$ for some nonnegative integer m.
15. In $\mathrm{H}(\Omega)$, the set of functions which vanishes on a prescribed set $U \subseteq \Omega$, i.e.,
$$I(U) := \{f \in \mathrm{H}(\Omega) : \quad f(\zeta) = 0, \ \zeta \in U\},$$
is an ideal.
16. Let Ω be an open connected set in $\mathbb{C}$. [Rud74, Theorems 15.11, 15.13] implies the following:
    (a) $I(U) \neq \{0\}$ if and only if U is a countable set, with no accumulations points in Ω.
    (b) Let U be a countable subset of Ω with no accumulation points in Ω. Assume that for each $\zeta \in U$ one is given a nonnegative integer $m(\zeta)$ and $m(\zeta) + 1$ complex numbers $w_{0,\zeta}, \ldots, w_{m(\zeta),\zeta}$. Then there exists $f \in \mathrm{H}(\Omega)$ such that $f^{(n)}(\zeta) = n! w_{n,\zeta}, n = 0, \ldots, m(\zeta)$, for all $\zeta \in U$. Furthermore, if all $w_{n,\zeta} = 0$, then there exists $g \in \mathrm{H}(\Omega)$ such that all zeros of g are in U and g has a zero of order $m(\zeta) + 1$ at each $\zeta \in U$.
    (c) Let $a, b \in \mathrm{H}(\Omega), ab \neq 0$. Then there exists $f \in \mathrm{H}(\Omega)$ such that $a = cf, b = df$, where $c, d \in \mathrm{H}(\Omega)$ and c, d do not have a common zero in Ω.
    (d) Let $c, d \in \mathrm{H}(\Omega)$ and assume that c, d do not have a common zero in Ω. Let U be the zero set of c in Ω, and denote by $m(\zeta) \geq 1$ the multiplicity of the zero $\zeta \in U$ of c. Then there exists $g \in \mathrm{H}(\Omega)$ such that $(e^g)^{(n)}(\zeta) = d^{(n)}(\zeta)$ for $n = 0, \ldots, m(\zeta)$, for all $\zeta \in U$. Hence, $p = \frac{e^g - d}{c} \in \mathrm{H}(\Omega)$ and $e^g = pc + d$ is a unit in $\mathrm{H}(\Omega)$.
    (e) For $a, b \in \mathrm{H}(\Omega)$ there exists $p \in \mathrm{H}(\Omega)$ such $(a, b) = pa + b$.
    (f) For $a, b, c \in \mathrm{H}(\Omega)$ one has $(a, b, c) = p(a, b) + c = p(xa + b) + c$. Hence, $\mathrm{H}(\Omega)$ is EDD.
17. Let $I \subset \mathbb{C}[x, y]$ be the ideal given by the condition $p(0, 0) = 0$. Then I is generated by x and y, and $(x, y) = 1$. I is not principal and $\mathbb{C}[x, y]$ is not BD.
18. $\mathbb{D}[x, y]$ is not BD.
19. $\mathbb{Z}[\sqrt{-5}]$ is an integral domain that is not a GCDD, since $2 + 2\sqrt{-5}$ and 6 have no greatest common divisor. This can be seen by using the norm $N(a + b\sqrt{-5}) = a^2 + 5b^2$.

32.2 Equivalence of Matrices

In this section, we introduce matrices over an integral domain. Since any domain $\mathbb{D}$ can be viewed as a subset of its quotient field F, the notion of determinant, minor, rank, and adjugate in Chapters 1, 2, and 4 can be applied to these matrices. It is an interesting problem to determine whether one given matrix can be transformed to another by left multiplication, right multiplication, or multiplication on both sides, using only matrices invertible with the domain. These are equivalence relations and the problem is to characterize left (row) equivalence classes, right (columns) equivalence classes, and equivalence classes in $\mathbb{D}^{m\times n}$. For BD, the left equivalence classes are characterized by their Hermite normal form, which are attributed to Hermite. For EDD, the equivalence classes are characterized by their Smith normal form.

Definitions:

For a set S, denote by $S^{m\times n}$ the set of all $m \times n$ matrices $A = [a_{ij}]_{i=j=1}^{i=m,j=n}$, where each $a_{ij} \in S$.

For positive integers $p \leq q$, denote by $Q_{p,q}$ the set of all subsets $\{i_1, \ldots, i_p\} \subset \{1, 2, \ldots q\}$ of cardinality p, where we assume that $1 \leq i_1 < \ldots < i_p \leq q$.

$U \in \mathbb{D}^{n\times n}$ is **$\mathbb{D}$-invertible** (**unimodular**), if there exists $V \in \mathbb{D}^{n\times n}$ such that $UV = VU = I_n$.

$\mathrm{GL}(n, \mathbb{D})$ denotes the group of $\mathbb{D}$-invertible matrices in $\mathbb{D}^{n\times n}$.

Let $A, B \in \mathbb{D}^{m\times n}$. Then A and B are **column equivalent**, **row equivalent**, and **equivalent** if the following conditions hold, respectively:

$$\begin{aligned} &B = AP \quad \text{for some } P \in \mathrm{GL}(n, \mathbb{D}) \quad (A \sim_c B),\\ &B = QA \quad \text{for some } Q \in \mathrm{GL}(m, \mathbb{D}) \quad (A \sim_r B),\\ &B = QAP \quad \text{for some } P \in \mathrm{GL}(n, \mathbb{D}),\ Q \in \mathrm{GL}(m, \mathbb{D}) \quad (A \sim B).\end{aligned}$$

For $A \in \mathbb{D}_g^{m\times n}$, let

$$\begin{aligned} &\mu(\alpha, A) = \text{g.c.d. } \{\det A[\alpha, \theta],\ \theta \in Q_{k,n}\}, \quad \alpha \in Q_{k,m},\\ &\nu(\beta, A) = \text{g.c.d. } \{\det A[\phi, \beta],\ \phi \in Q_{k,m}\}, \quad \beta \in Q_{k,n},\\ &\delta_k(A) = \text{g.c.d. } \{\det A[\phi, \theta],\ \phi \in Q_{k,m},\ \theta \in Q_{k,n}\}.\end{aligned}$$

$\delta_k(A)$ is the k-th **determinant invariant** of A.

For $A \in \mathbb{D}_g^{m\times n}$,

$$\begin{aligned} &i_j(A) = \frac{\delta_j(A)}{\delta_{j-1}(A)}, \quad j = 1, \ldots, \text{rank } A, \quad (\delta_0(A) = 1),\\ &i_j(A) = 0 \quad \text{for rank } A < j \leq \min(m, n),\end{aligned}$$

are called the **invariant factors** of A. $i_j(A)$ is a **trivial** factor if $i_j(A)$ is unit in $\mathbb{D}_g$. We adopt the **normalization** $i_j(A) = 1$ for any trivial factor of A. For $\mathbb{D} = \mathbb{Z}, \mathbb{Z}[x], F[x]$, we adopt the normalizations given in the previous section in Examples 1, 6, and 12, respectively.

Assume that $\mathbb{D}[x]$ is a GCDD. Then the invariant factors of $A \in \mathbb{D}[x]^{m\times n}$ are also called **invariant polynomials**.

$D = [d_{ij}] \in \mathbb{D}^{m\times n}$ is a **diagonal** matrix if $d_{ij} = 0$ for all $i \neq j$. The entries $d_{11}, \ldots, d_{\ell\ell}$, $\ell = \min(m, n)$, are called the **diagonal entries** of D. D is denoted as $D = \operatorname{diag}(d_{11}, \ldots, d_{\ell\ell}) \in \mathbb{D}^{m\times n}$.

Denote by $\Pi_n \subset \mathrm{GL}(n, \mathbb{D})$ the group of $n \times n$ permutation matrices.

An $\mathbb{D}$-invertible matrix $U \in \mathrm{GL}(n, \mathbb{D})$ is **simple** if there exists $P, Q \in \Pi_n$ such that $U = P \begin{bmatrix} V & 0 \\ 0 & I_{n-2} \end{bmatrix} Q$, where $V = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} \in \mathrm{GL}(2, \mathbb{D})$, i.e., $\alpha\delta - \beta\gamma$ is $\mathbb{D}$-invertible.

U is **elementary** if U is of the above form and $V = \begin{bmatrix} \alpha & 0 \\ \gamma & \delta \end{bmatrix} \in \mathrm{GL}(2, \mathbb{D})$, i.e., α, δ are invertible.

For $A \in \mathbb{D}^{m\times n}$, the following row (column) operations are **elementary row operations**:

(a) Interchange any two rows (columns) of A.
(b) Multiply row (column) i by an invertible element a.
(c) Add to row (column) j b times row (column) i $(i \neq j)$.

For $A \in \mathbb{D}^{m\times n}$, the following row (column) operations are **simple row operations**:

(d) Replace row (column) i by a times row (column) i plus b times row (column) j, and row (column) j by c times row (column) i plus d times row (column) j, where $i \neq j$ and $ad - bc$ is invertible in $\mathbb{D}$.

$B = [b_{ij}] \in \mathbb{D}^{m\times n}$ is in **Hermite normal** form if the following conditions hold. Let $r = \text{rank } B$. First, the i-th row of B is a nonzero row if and only if $i \leq r$. Second, let b_{in_i} be the first nonzero entry in the i-th row for $i = 1, \ldots, r$. Then $1 \leq n_1 < n_2 < \cdots < n_r \leq n$.

$B \in \mathbb{D}_g^{m\times n}$ is in **Smith normal** form if B is a diagonal matrix $B = \text{diag}\,(b_1, \ldots, b_r, 0, \ldots, 0)$, $b_i \neq 0$, for $i = 1, \ldots, r$ and $b_{i-1}|b_i$ for $i = 2, \ldots, r$.

Facts:

Most of the results of this section can be found in [McD84]. Some special results of this section are given in [Fri81] and [Fri]. For information about equivalence over fields, see Chapter 1 and Chapter 2.

1. The cardinality of $Q_{p,q}$ is $\binom{q}{p}$.
2. If U is $\mathbb{D}$-invertible, then $\det U$ is a unit in $\mathbb{D}$. Conversely, if $\det U$ is a unit, then U is $\mathbb{D}$-invertible, and its inverse U^{-1} is given by $U^{-1} = (\det U)^{-1}\text{adj}\, U$.
3. For $A \in \mathbb{D}^{m\times n}$, the rank of A is the maximal size of the nonvanishing minor. (The rank of zero matrix is 0.)
4. Column equivalence, row equivalence, and equivalence of matrices are equivalence relations in $\mathbb{D}^{m\times n}$.
5. For any $A, B \in \mathbb{D}^{m\times n}$, one has $A \sim_r B \iff A^T \sim_c B^T$. Hence, it is enough to consider the row equivalence relation.
6. For $A, B \in \mathbb{D}_g^{m\times n}$, the Cauchy–Binet formula (Chapter 4) yields
$$\begin{aligned} &\mu(\alpha, A) \equiv \mu(\alpha, B) \quad \text{for all } \alpha \in Q_{k,m} \quad \text{if } A \sim_c B,\\ &\nu(\beta, A) \equiv \nu(\beta, B) \quad \text{for all } \beta \in \mathrm{Q}_{k,n} \quad \text{if } A \sim_r B,\\ &\delta_k(A) \equiv \delta_k(B) \quad \text{if } A \sim B, \end{aligned}$$
for $k = 1, \ldots, \min(m, n)$.
7. Any elementary matrix is a simple matrix, but not conversely.
8. The elementary row and column operations can be carried out by multiplications by A by suitable elementary matrices from the left and the right, respectively.
9. The simple row and column operations are carried out by multiplications by A by suitable simple matrices U from the left and right, respectively.
10. Let $\mathbb{D}_b$ be a Bezout domain, $A \in \mathbb{D}_b^{m\times n}$, rank $A = r$. Then A is row equivalent to $B = [b_{ij}] \in \mathbb{D}_b^{m\times n}$, in a Hermite normal form, which satisfies the following conditions.
    Let b_{in_i} be the first nonzero entry in the i-th row for $i = 1, \ldots, r$. Then $1 \leq n_1 < n_2 < \cdots < n_r \leq n$ are uniquely determined and the elements b_{in_i}, $i = 1, \ldots, r$ are uniquely determined, up to units, by the conditions
$$\begin{aligned} &\nu((n_1, \ldots, n_i), A) = b_{1n_1} \cdots b_{in_i}, \quad i = 1, \ldots, r,\\ &\nu(\alpha, A) = 0,\ \alpha \in Q_{i,n_i-1}, \quad i = 1, \ldots, r. \end{aligned}$$

The elements $b_{jn_i},\ j = 1, \ldots, i-1$ are then successively uniquely determined up to the addition of arbitrary multiples of b_{in_i}. The remaining elements b_{ik} are now uniquely determined. The $\mathbb{D}$-invertible matrix Q, such that $B = QA$, can be given by a finite product of simple matrices.

If b_{in_i} in the Hermite normal form is invertible, we assume the normalization conditions $b_{in_i} = 1$ and $b_{jn_i} = 0$ for $i < j$.

11. For Euclidean domains, we assume normalization conditions either $b_{jn_i} = 0$ or $d(b_{jn_i}) < d(b_{in_i})$ for $j < i$. Then for any $A \in \mathbb{D}_e^{m\times n}$, in a Hermite normal form $B = QA,\ Q \in \mathrm{GL}_m(\mathbb{D}_e)$ Q is a product of a finite elementary matrices.
12. $U \in \mathrm{GL}(n, \mathbb{D}_e)$ is a finite product of elementary $\mathbb{D}$-invertible matrices.
13. For $\mathbb{Z}$, we assume the normalization $b_{in_i} \geq 1$ and $0 \leq b_{jn_i} < b_{in_i}$ for $j < i$. For $F[x]$, we assume that b_{in_i} is a monic polynomial and $\deg b_{jn_i} < \deg b_{in_i}$ for $j < i$. Then for $\mathbb{D}_e = \mathbb{Z}, F[x]$, any $A \in \mathbb{D}_e^{m\times n}$ has a unique Hermite normal form.
14. $A, B \in \mathbb{D}_b$ are row equivalent if and only if A and B are row equivalent to the same Hermite normal form.
15. $A \in F^{m\times n}$ can be brought to its unique Hermite normal form, called the *reduced row echelon form* (RREF),
$$b_{in_i} = 1, \quad b_{jn_i} = 0, \quad j = 1, \ldots, i-1, \quad i = 1, \ldots, r = \text{rank } A,$$
by a finite number of elementary row operations. Hence, $A, B \in F^{m\times n}$ are row equivalent if and only if $r = \text{rank } A = \text{rank } B$ and they have the same RREF. (See Chapter 1.)
16. For $A \in \mathbb{D}_g^{m\times n}$ and $1 \leq p < q \leq \min(m, n)$, $\delta_p(A) | \delta_q(A)$.
17. For $A \in \mathbb{D}_g^{m\times n}$, $i_{j-1}(A) | i_j(A)$ for $j = 2, \ldots, \text{rank } A$.
18. Any $0 \neq A \in \mathbb{D}_{ed}^{m\times n}$ is equivalent to its Smith normal form
$$B = \text{diag } (i_1(A), \ldots, i_r(A), 0, \ldots, 0),$$
where $r = \text{rank } A$ and $i_1(A), \ldots, i_r(A)$ are the invariants factors of A.
19. $A, B \in \mathbb{D}_{ed}^{m\times n}$ are equivalent if and only if A and B have the same rank and the same invariant factors.

Examples:

1. Let $A = \begin{bmatrix} 1 & a \\ 0 & 0 \end{bmatrix}, B = \begin{bmatrix} 1 & b \\ 0 & 0 \end{bmatrix} \in \mathbb{D}^{2\times 2}$ be two Hermite normal forms. It is straightforward to show that $A \sim_r B$ if and only if $a = b$. Assume that $\mathbb{D}$ is a BD and let $a \neq 0$. Then rank $A = 1, \nu((1), A) = 1, \{\{\nu((2), A)\}\} = \{\{a\}\}, \nu((1,2), A) = 0$. If $\mathbb{D}$ has units other than 1, it follows that $\nu(\beta, A)$ for all $\beta \in Q_{k,2}, k = 1, 2$ do not determine the row equivalence class of A.
2. Let $A = \begin{bmatrix} a & c \\ b & d \end{bmatrix} \in \mathbb{D}_b^{2\times 2}$. Then there exists $u, v \in \mathbb{D}_b$ such that $ua + vb = (a, b) = \nu((1), A)$. If $(a, b) \neq 0$, then $1 = (u, v)$. If $a = b = 0$, choose $u = 1, v = 0$. Hence, there exists $x, y \in \mathbb{D}_b$ such that $yu - xv = 1$. Thus, $V = \begin{bmatrix} u & v \\ x & y \end{bmatrix} \in \mathrm{GL}(2, \mathbb{D}_b)$ and $VA = \begin{bmatrix} (a,b) & c' \\ b' & d' \end{bmatrix}$. Clearly $b' = xa + yb = (a, b)e$. Hence, $\begin{bmatrix} 1 & 0 \\ -e & 1 \end{bmatrix} VA = \begin{bmatrix} (a,b) & c' \\ 0 & f \end{bmatrix}$ is a Hermite normal form of A. This construction is easily extended to obtain a Hermite normal form for any $A \in \mathbb{D}_b^{m\times n}$, using simple row operations.
3. Let $A \in \mathbb{D}_e^{2\times 2}$ as in the previous example. Assume that $ab \neq 0$. Change the two rows of A if needed to assume that $d(a) \leq d(b)$. Let $a_1 = b, a_2 = a$ and do the first step of Euclid's algorithm: $a_1 = t_1 a_2 + a_3$, where $a_3 = 0$ or $d(a_3) < d(a_2)$. Let $V = \begin{bmatrix} 1 & 0 \\ -t_1 & 1 \end{bmatrix} \in \mathrm{GL}(2, \mathbb{D}_e)$

be an elementary matrix. Then $A_1 = VA = \begin{bmatrix} a_2 & * \\ a_3 & * \end{bmatrix}$. If $a_3 = 0$, then A_1 has a Hermite normal form. If $a_3 \neq 0$, continue as before. Since Euclid's algorithm terminates after a finite number of steps, it follows that A can be put into Hermite normal form by a finite number of elementary row operations. This statement holds similarly in the case $ab = 0$. This construction is easily extended to obtain a Hermite normal form for any $A \in \mathbb{D}_e^{m\times n}$ using elementary row operations.

4. Assume that $\mathbb{D}$ is a BD and let $A = \begin{bmatrix} a & b \\ 0 & c \end{bmatrix} \in \mathbb{D}^{2\times 2}$. Note that $\delta_1(A) = (a, b, c)$. If A is equivalent to a Smith normal form, then there exists $V, U \in \mathrm{GL}(2, D)$ such that $VAU = \begin{bmatrix} (a,b,c) & * \\ * & * \end{bmatrix}$. Assume that $V = \begin{bmatrix} p & q \\ \tilde{q} & \tilde{p} \end{bmatrix}, U = \begin{bmatrix} x & \tilde{y} \\ y & \tilde{x} \end{bmatrix}$. Then there exist $p, q, x, y \in \mathbb{D}$ such that $(px)a + (py)b + (qy)c = (a, b, c)$. Thus, if each $A \in \mathbb{D}^{2\times 2}$ is equivalent to Smith normal form in $\mathbb{D}^{2\times 2}$, then it follows that $\mathbb{D}$ is an EDD.

   Conversely, suppose that $\mathbb{D}$ is an EDD. Then $\mathbb{D}$ is also a BD. Let $A \in \mathbb{D}^{2\times 2}$. First, bring A to an upper triangular Hermite normal form using simple row operations: $A_1 = WA = \begin{bmatrix} a & b \\ 0 & c \end{bmatrix}, W \in \mathrm{GL}(2, \mathbb{D})$. Note that $\delta_1(A) = \delta_1(A_1) = (a, b, c)$. Since $\mathbb{D}$ is an EDD, there exist $p, q, x, y \in \mathbb{D}$ such that $(px)a + (py)b + (qy)c = (a, b, c)$. If $(a, b, c) \neq (0, 0, 0)$, then $(p, q) = (x, y) = 1$. Otherwise $A = A_1 = 0$ and we are done. Hence, there exist $\tilde{p}, \tilde{q}, \tilde{x}, \tilde{y}$ such that $p\tilde{p} - q\tilde{q} = x\tilde{x} - y\tilde{y} = 1$. Let $V = \begin{bmatrix} p & q \\ \tilde{q} & \tilde{p} \end{bmatrix}, U = \begin{bmatrix} x & \tilde{y} \\ y & \tilde{x} \end{bmatrix}$. Thus, $G = VA_1U = \begin{bmatrix} \delta_1(A) & g_{12} \\ g_{21} & g_{22} \end{bmatrix}$. Since $\delta_1(G) = \delta_1(A)$, we deduce that $\delta_1(A)$ divides g_{12} and g_{21}. Apply appropriate elementary row and column operations to deduce that A is equivalent to a diagonal matrix $C = \mathrm{diag}\,(i_1(A), d_2)$. As $\delta_2(C) = i_1(A)d_2 = \delta_2(A)$, we see that C is in Smith normal form.

   These arguments are easily extended to obtain a Smith normal form for any $A \in \mathbb{D}_{ed}^{m\times n}$, using simple row and column operations.
5. The converse of Fact 6 is false, as can be seen by considering $A = \begin{bmatrix} 2 & 2 \\ x & x \end{bmatrix}, B = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} \in \mathbb{Z}[x]^{2\times 2}$. $\mu(\{1\}, A) = \mu(\{1\}, B) = 1$, $\mu(\{2\}, A) = \mu(\{2\}, B) = 1$, $\mu(\{1, 2\}, A) = \mu(\{1, 2\}, B) = 0$, but there does not exist a $\mathbb{D}$-invertible P such that $PA = B$.
6. Let $\mathbb{D}$ be an integral domain and assume that $p(x) = x^m + \sum_{i=1}^m a_i x^{m-i} \in \mathbb{D}[x]$ is a monic polynomial of degree $m \geq 2$. Let $C(p) \in \mathbb{D}^{m\times m}$ be the companion matrix (see Chapter 4). Then $\det\,(xI_m - C(p)) = p(x)$. Assume that $\mathbb{D}[x]$ is a GCDD. Let $C(p)(x) = xI_m - C(p) \in \mathbb{D}[x]^{m\times m}$. By deleting the last column and first row, we obtain a triangular $(m-1)\times(m-1)$ submatrix with -1s on the diagonal, so it follows that $\delta_i(C(p)(x)) = 1$ for $i = 1, \ldots, m-1$. Hence, the invariant factors of $C(p)(x)$ are $i_1(C(p)(x)) = \ldots = i_{m-1}(C(p)(x)) = 1$ and $i_m(C(p)(x)) = p(x)$. If $\mathbb{D}$ is a field, then $C(p)(x)$ is equivalent over $\mathbb{D}[x]$ to $\mathrm{diag}\,(1, \ldots, 1, p(x))$.

32.3 Linear Equations over Bezout Domains

Definitions:

M is a $\mathbb{D}$-**module** if **M** is an additive group with respect to the operation + and **M** admits a multiplication by a **scalar** $a \in \mathbb{D}$, i.e., there exists a mapping $\mathbb{D} \times \mathbf{M} \to \mathbf{M}$ which satisfies the standard distribution properties and $1\mathbf{v} = \mathbf{v}$ for all $\mathbf{v} \in \mathbf{M}$ (the latter requirement sometimes results in the module being called unital). (For a field F, a module **M** is a vector space over F.)

M is **finitely generated** if there exist $\mathbf{v}_1, \ldots, \mathbf{v}_n \in \mathbf{M}$ so that every $\mathbf{v} \in \mathbf{M}$ is a **linear**

combination of $\mathbf{v}_1, \ldots, \mathbf{v}_n$, over $\mathbb{D}$, i.e., $\mathbf{v} = a_1\mathbf{v}_1 + \ldots + a_n\mathbf{v}_n$ for some $a_1, \ldots, a_n \in \mathbb{D}$. $\mathbf{v}_1, \ldots, \mathbf{v}_n$ is a **basis** of $\mathbf{M}$ if every $\mathbf{v}$ can be written as a unique linear combination of $\mathbf{v}_1, \ldots, \mathbf{v}_n$. $\dim \mathbf{M} = n$ means that $\mathbf{M}$ has a basis of n elements.

$\mathbf{N} \subseteq \mathbf{M}$ is a $\mathbb{D}$**-submodule** of $\mathbf{M}$ if $\mathbf{N}$ is closed under the addition and multiplication by scalars.

$\mathbb{D}^n (= \mathbb{D}^{n\times 1})$ is a $\mathbb{D}$-module. It has a **standard** basis $\mathbf{e}_i$ for $i = 1, \ldots, n$, where $\mathbf{e}_i$ is the i-th column of the identity matrix I_n.

For any $A \in \mathbb{D}^{m\times n}$, the **range** of A, denoted by range(A), is the set of all linear combinations of the columns of A.

The **kernel** of A, denoted by $\ker(A)$, is the set of all solutions to the homogeneous equation $A\mathbf{x} = \mathbf{0}$.

Consider a system of m linear equations in n unknowns:

$\sum_{j=1}^{n} a_{ij}x_j = b_j, \quad i = 1, \ldots, m$, where $a_{ij}, b_i \in \mathbb{D}$ for $i = 1, \ldots, m, \ j = 1, \ldots, n$. In matrix notation this system is $A\mathbf{x} = \mathbf{b}$, where $A = [a_{ij}] \in \mathbb{D}^{m\times n}, \ \mathbf{x} = [x_1, \ldots, x_n]^T \in \mathbb{D}^n, \ \mathbf{b} = [b_1, \ldots, b_m]^T \in \mathbb{D}^m$. A and $[A, \mathbf{b}] \in \mathbb{D}^{m\times(n+1)}$ are called the **coefficient** matrix and the **augmented** matrix, respectively.

Let $A \in \mathrm{H}_0^{m\times n}$. Then $A = A(z) = [a_{ij}(z)]_{i=j=1}^{m,n}$ and $A(z)$ has the McLaurin expansion $A(z) = \sum_{k=0}^{\infty} A_k z^k$, where $A_k \in \mathbb{C}^{m\times n}, k = 0, \ldots$. Here, each $a_{ij}(z)$ has convergent McLaurin series for $|z| < R(A)$ for some $R(A) > 0$.

The invariant factors of A are called the **local invariant polynomials** of A, which are normalized to be of the form $i_k(A) = z^{i_k}$ for $0 \le i_1 \le i_2 \le \ldots \le i_r$, where $r = \text{rank } A$.

The integer i_r is the **index** of A and is denoted by $\eta = \eta(A)$. For a nonnegative integer p, denote by $\mathcal{K}_p = \mathcal{K}_p(A)$ the number of local invariant polynomials of A whose degree is equal to p.

Facts:

For modules, see [ZS58], [DF04], and [McD84]. The solvability of linear systems over EDD can be traced to [Hel43] and [Kap49]. The results for BD can be found in [Fri81] and [Fri]. The results for H_0 are given in [Fri80]. The general theory of solvability of the systems of equations over commutative rings is discussed in [McD84, Exc. I.G.7–I.G.8]. (See Chapter 1 for information about solvability over fields.)

1. The system $A\mathbf{x} = \mathbf{b}$ is solvable over a Bezout domain $\mathbb{D}_b$ if and only if $r = \text{rank } A = \text{rank } [A, \mathbf{b}]$ and $\delta_r(A) = \delta_r([A, \mathbf{b}])$, which is equivalent to the statement that A and $[A, \mathbf{b}]$ have the same set of invariant factors, up to invertible elements. For a field F, this result reduces to the equality rank $A = \text{rank } [A, \mathbf{b}]$.
2. For $A \in \mathbb{D}_b^{m\times n}$, range A and $\ker A$ are modules in $\mathbb{D}_b^m$ and $\mathbb{D}_b^n$ having finite bases with rank A and null A elements, respectively. Moreover, the basis of $\ker A$ can be completed to a basis of $\mathbb{D}_b^n$.
3. For $A, B \in \mathrm{H}_0^{m\times n}$, let $C(z) = A(z) + z^{k+1}B(z)$, where k is a nonnegative integer. Then A and C have the same local invariant polynomials up to degree k. Moreover, if k is equal to the index of A, and A and C have the same rank, then A is equivalent to C.
4. Consider a system of linear equations over H_0 $A(z)\mathbf{u}(z) = \mathbf{b}(z)$, where $A(z) \in \mathrm{H}_0^{m\times n}$ and $\mathbf{b}(z) = \sum_{k=0}^{\infty} \mathbf{b}_k z^k \in \mathrm{H}_0^m, \quad \mathbf{b}_k \in \mathbb{C}^m, \ k = 0, \ldots$. Look for the power series solution $\mathbf{u}(z) = \sum_{k=0}^{\infty} \mathbf{u}_k z^k$, where $\mathbf{u}_k \in \mathbb{C}^n, \ k = 0, \ldots$. Then $\sum_{j=0}^{k} A_{k-j}\mathbf{u}_j = \mathbf{b}_k$, for $k = 0, \ldots$. This system is solvable for $k = 0, \ldots, q \in \mathbb{Z}_+$ if and only if $A(z)$ and $[A(z), \mathbf{b}(z)]$ have the same local invariant polynomials up to degree q.
5. Suppose that $A(z)\mathbf{u}(z) = \mathbf{b}(z)$ is solvable over H_0. Let $q = \eta(A)$ and suppose that $\mathbf{u}_0, \ldots, \mathbf{u}_q$ satisfies the system of equations, given in the previous fact, for $k = 0, \ldots, q$. Then there exists a solution $\mathbf{u}(z) \in \mathrm{H}_0^n$ satisfying $\mathbf{u}(0) = \mathbf{u}_0$.
6. Let $q \in \mathbb{Z}_+$ and $\mathbf{W}_q \subset \mathbb{C}^n$ be the subspace of all vectors $\mathbf{w}_0$ such that $\mathbf{w}_0, \ldots, \mathbf{w}_q$

is a solution to the homogenous system $\sum_{j=0}^{k} A_{k-j}\mathbf{w}_j = 0$, for $k = 0, \ldots, q$. Then $\dim \mathbf{W}_q = n - \sum_{j=0}^{q} \mathcal{K}_j(A)$. In particular, for $\eta = \eta(A)$ and any $\mathbf{w}_0 \in \mathbf{W}_\eta$ there exists $\mathbf{w}(z) \in \mathrm{H}_0^n$ such that $A(z)\mathbf{w}(z) = \mathbf{0}$, $\mathbf{w}(0) = \mathbf{w}_0$.

32.4 Strict Equivalence of Pencils

Definitions:

A matrix $A(x) \in \mathbb{D}[x]^{m\times n}$ is a **pencil** if $A(x) = A_0 + xA_1$, $A_0, A_1 \in \mathbb{D}^{m\times n}$.

A pencil $A(x)$ is **regular** if $m = n$ and $\det A(x)$ is not the zero polynomial. Otherwise, $A(x)$ is a **singular** pencil.

Associate with a pencil $A(x) = A_0 + xA_1 \in \mathbb{D}[x]^{m\times n}$ the **homogeneous** pencil $A(x_0, x_1) = x_0A_0 + x_1A_1 \in \mathbb{D}[x_0, x_1]^{m\times n}$.

Two pencils $A(x), B(x) \in \mathbb{D}[x]^{m\times n}$ are **strictly** equivalent, denoted by $A(x)\overset{s}{\sim}B(x)$, if $B(x) = QA(x)P$ for some $P \in \mathrm{GL}_n(\mathbb{D})$, $Q \in \mathrm{GL}_m(\mathbb{D})$. Similarly, two homogeneous pencils $A(x_0, x_1)$, $B(x_0, x_1) \in \mathbb{D}[x_0, x_1]^{m\times n}$ are **strictly** equivalent, denoted by $A(x_0, x_1)\overset{s}{\sim}B(x_0, x_1)$, if $B(x_0, x_1) = QA(x_0, x_1)P$ for some $P \in \mathrm{GL}_n(\mathbb{D})$, $Q \in \mathrm{GL}_m(\mathbb{D})$.

For a UFD $\mathbb{D}_u$ let $\delta_k(x_0, x_1)$, $i_k(x_0, x_1)$ be the invariant determinants and factors of $A(x_0, x_1)$, respectively, for $k = 1, \ldots, \mathrm{rank}\ A(x_0, x_1)$. They are called **homogeneous** determinants and the invariant **homogeneous** polynomials (factors), respectively, of $A(x_0, x_1)$. (Sometimes, $\delta_k(x_0, x_1)$, $i_k(x_0, x_1), k = 1, \ldots, \mathrm{rank}\ A(x_0, x_1)$ are called the homogeneous determinants and the invariant homogeneous polynomials $A(x)$.)

Let $A(x) \in F[x]^{m\times n}$ and consider the module $\mathbf{M} \subset F[x]^n$ of all solutions of $A(x)\mathbf{w}(x) = 0$. The set of all solutions $\mathbf{w}(x)$ is an $F[x]$-module $\mathbf{M}$ with a finite basis $\mathbf{w}_1(x), \ldots, \mathbf{w}_s(x)$, where $s = n - \mathrm{rank}\ A(x)$. Choose a basis $\mathbf{w}_1(x), \ldots, \mathbf{w}_s(x)$ in $\mathbf{M}$ such that $\mathbf{w}_k(x) \in \mathbf{M}$ has the lowest degree among all $\mathbf{w}(x) \in \mathbf{M}$, which are linearly independent over $F[x]$ of $\mathbf{w}_1, \ldots, \mathbf{w}_{k-1}(x)$ for $k = 1, \ldots, s$. Then the **column indices** $\alpha_1 \leq \alpha_2 \leq \ldots \leq \alpha_s$ of $A(x)$ are given as $\alpha_k = \deg \mathbf{w}_k(x)$, $k = 1, \ldots, s$. The **row indices** $0 \leq \beta_1 \leq \beta_2 \leq \ldots \leq \beta_t$, $t = m - \mathrm{rank}\ A(x)$, of $A(x)$, are the column indices of $A(x)^{\mathrm{T}}$.

Facts:

The notion of strict equivalence of $n \times n$ regular pencils over the fields goes back to Weierstrass [Wei67]. The notion of strict similarity of $m \times n$ matrices over the fields is due to Kronecker [Kro90]. Most of the details can be found in [Gan59]. Some special results are proven in [Fri]. For information about matrix pencils over fields, see Section 56.1.

1. Let $A_0, A_1, B_0, B_1 \in \mathbb{D}^{m\times n}$. Then $A_0 + xA_1\overset{s}{\sim}B_0 + xB_0 \iff x_0A_0 + x_1A_1\overset{s}{\sim}B_0x_0 + B_1x_1$.
2. Let $A_0, A_1 \in \mathbb{D}_u$. Then the invariant determinants and the invariant polynomials $\delta_k(x_0, x_1)$, $i_k(x_0, x_1)$, $k = 1, \ldots, \mathrm{rank}\ x_0A_0 + x_1A_1$, of $x_0A_0 + x_1A_1$ are homogeneous polynomials. Moreover, if $\delta_k(x)$ and $i_k(x)$ are the invariant determinants and factors of the pencil $A_0 + xA_1$ for $k = 1, \ldots, \mathrm{rank}\ A_0 + xA_1$, then $\delta_k(x) = \delta_k(1, x)$, $i_k(x) = i_k(1, x)$, for $k = 1, \ldots, \mathrm{rank}\ A_0 + xA_1$.
3. [Wei67] Let $A_0+xA_1 \in F[x]^{n\times n}$ be a regular pencil. Then a pencil $B_0+xB_1 \in F[x]^{n\times n}$ is strictly equivalent to $A_0 + xA_1$ if and only if $A_0 + xA_1$ and $B_0 + xB_1$ have the same invariant polynomials over $F[x]$.
4. [Fri] Let $A_0 + xA_1, B_0 + xB_1 \in \mathbb{D}[x]^{n\times n}$. Assume that $A_1, B_1 \in \mathrm{GL}_n(\mathbb{D})$. Then $A_0 + xA_1\overset{s}{\sim}B_0 + xB_1 \iff A_0 + xA_1 \sim B_0 + xB_1$.
5. [Gan59] The column (row) indices are independent of a particular allowed choice of

a basis $\mathbf{w}_1(x), \ldots, \mathbf{w}_s(x)$.

6. For singular pencils the invariant homogeneous polynomials alone do not determine the class of strictly equivalent pencils.
7. [Kro90], [Gan59] The pencils $A(x), B(x) \in F[x]^{m \times n}$ are strictly equivalent if and only if they have the same invariant homogeneous polynomials and the same row and column indices.

This chapter uses the notations, definitions, and facts given in Chapter 32. The aim of this chapter is to acquaint the reader with two difficult problems in matrix theory:

1. Similarity of matrices over integral domains, which are not fields.
2. Simultaneous similarity of tuples of matrices over $\mathbb{C}$.

Problem 1 is notoriously difficult. We show that for the local ring H_0 this problem reduces to Problem 2 for certain kind of matrices. We then discuss certain special cases of Problem 2 as simultaneous similarity of tuples of matrices to upper triangular and diagonal matrices. The L-property of pairs of matrices, which is discussed next, is closely related to simultaneous similarity of pair of matrices to a diagonal pair. The rest of the chapter is devoted to a "solution" of Problem 2, by the author, in terms of basic notions of algebraic geometry.

33.1 Similarity of Matrices

The classical result of K. Weierstrass [Wei67] states that the similarity class of $A \in F^{n\times n}$ is determined by the invariant factors of $-A+xI_n$ over $F[x]$. (See Chapter 6 and Chapter 32.) For a given $A, B \in F^{n\times n}$, one can easily determine if A and B are similar, by considering *only* the ranks of three specific matrices associated with A, B [GB77]. It is well known that it is a difficult problem to determine if $A, B \in \mathbb{D}^{n\times n}$ are $\mathbb{D}$-similar for most integral domains that are not fields. The emphasis of this chapter is the similarity over the local field H_0. The subject of similarity of matrices over H_0 arises naturally in theory linear differential equations having singularity with respect to a parameter. It was studied by Wasow in [Was63], [Was77], and [Was78].

Definitions:

For $E \in \mathbb{D}^{m\times n}, G \in \mathbb{D}^{p\times q}$ extend the definition of the **tensor** or **Kronecker** product $E \otimes G \in \mathbb{D}^{mp\times nq}$ of E with G to the domain $\mathbb{D}$ in the obvious way. (See Section 11.4.)

$A, B \in \mathbb{D}^{m\times m}$ are called **similar**, denoted by $A \approx B$ if $B = QAQ^{-1}$, for some $Q \in \mathrm{GL}_m(\mathbb{D})$.

Let $A, B \in \mathrm{H}(\Omega)^{n\times n}$. Then A and B are called **analytically similar**, denoted as $A \overset{a}{\approx} B$, if A and B are similar over $\mathrm{H}(\Omega)$.

A and B are called **locally similar** if for any $\zeta \in \Omega$, the restrictions A_ζ, B_ζ of A, B to the local rings H_ζ, respectively, are similar over H_ζ.

A, B are called **point-wise** similar if $A(\zeta), B(\zeta)$ are similar matrices in $\mathbb{C}^{n\times n}$ for each $\zeta \in \Omega$.

A, B are called **rationally** similar, denoted as $A \overset{r}{\approx} B$, if A, B are similar over the quotient field $\mathcal{M}(\Omega)$ of $\mathrm{H}(\Omega)$.

Let $A, B \in \mathrm{H}_0^{n\times n}$:

$$A(x) = \sum_{k=0}^{\infty} A_k x^k, \quad |x| < R(A), \qquad B(x) = \sum_{k=0}^{\infty} B_k x^k, \quad |x| < R(B).$$

Then $\eta(A, B)$ and $\mathcal{K}_p(A, B)$ are the index and the number of local invariant polynomials of degree p of the matrix $I_n \otimes A(x) - B(x)^{\mathrm{T}} \otimes I_n$, respectively, for $p = 0, 1, \ldots$.

$\lambda(x)$ is called an **algebraic** function if there exists a monic polynomial $p(\lambda, x) = \lambda^n + \sum_{i=1}^{n} q_i(x)\lambda^{n-i} \in (\mathbb{C}[x])[\lambda]$ of λ-degree $n \geq 1$ such that $p(\lambda(x), x) = 0$ identically. Then $\lambda(x)$ is a multivalued function on $\mathbb{C}$, which has n **branches**. At each point $\zeta \in \mathbb{C}$ each branch $\lambda_j(x)$ of $\lambda(x)$ has **Puiseaux** expansion: $\lambda_j(x) = \sum_{i=0}^{\infty} b_{ji}(\zeta)(x-\zeta)^{\frac{i}{m}}$, which converges for $|x - \zeta| < R(\zeta)$, and some integer m depending on $p(x)$. $\sum_{i=0}^{m} b_{ji}(\zeta)(x-\zeta)^{\frac{i}{m}}$ is called the **linear part** of $\lambda_j(x)$ at ζ. Two distinct branches $\lambda_j(x)$ and $\lambda_k(x)$ are called **tangent** at $\zeta \in \mathbb{C}$ if the linear parts of $\lambda_j(x)$ and $\lambda_k(x)$ coincide at ζ. Each branch $\lambda_j(x)$ has Puiseaux expansion around ∞: $\lambda_j(x) = x^l \sum_{i=0}^{\infty} c_{ji} x^{-\frac{i}{m}}$, which converges for $|x| > R$. Here, l is the smallest nonnegative integer such that $c_{j0} \neq 0$ at least for some branch λ_j. $x^l \sum_{i=0}^{m} c_{ji} x^{-\frac{i}{m}}$ is called the **principal part** of $\lambda_j(x)$ at ∞. Two distinct branches $\lambda_j(x)$ and $\lambda_k(x)$ are called **tangent** at ∞ if the principal parts of $\lambda_j(x)$ and $\lambda_k(x)$ coincide at ∞.

Facts:

The standard results on the tensor products can be found in Chapter 11 or Chapter 14 or in [MM64]. Most of the results of this section related to the analytic similarity over H_0 are taken from [Fri80].

1. The similarity relation is an equivalence relation on $\mathbb{D}^{m\times m}$.
2. $A \approx B \iff A(x) = -A + xI \overset{s}{\sim} B(x) = -B + xI$.
3. Let $A, B \in F^{n\times n}$. Then A and B are similar if and only if the pencils $-A + xI$ and $-B + xI$ have the same invariant polynomials over $F[x]$.
4. If $E = [e_{ij}] \in \mathbb{D}^{m\times n}, G \in \mathbb{D}^{p\times q}$, then $E \otimes G$ can be viewed as the $m \times n$ block matrix $[e_{ij}G]_{i,j=1}^{m,n}$. Alternatively, $E \otimes G$ can be identified with the linear transformation
$$L(E, G) : \mathbb{D}^{q\times n} \to \mathbb{D}^{p\times m}, \quad X \to GXE^{\mathrm{T}}.$$
5. $(E \otimes G)(U \otimes V) = EU \otimes GV$ whenever the products EU and GV are defined. Also $(E \otimes G)^{\mathrm{T}} = E^{\mathrm{T}} \otimes G^{\mathrm{T}}$.
6. For $A, B \in \mathbb{D}^{n\times n}$, if A is similar to B, then
$$I_n \otimes A - A^{\mathrm{T}} \otimes I_n \sim I_n \otimes A - B^{\mathrm{T}} \otimes I_n \sim I_n \otimes B - B^{\mathrm{T}} \otimes I_n.$$
7. [Gur80] There are examples over Euclidean domains for which the reverse of the implication in Fact 6 does not hold.
8. [GB77] For $\mathbb{D} = F$, the reverse of the implication in Fact 6 holds.
9. [Fri80] Let $A \in F^{m\times m}$, $B \in F^{n\times n}$. Then
$$\text{null}\,(I_n \otimes A - B^{\mathrm{T}} \otimes I_m) \leq \frac{1}{2}(\text{null}\,(I_m \otimes A - A^{\mathrm{T}} \otimes I_m) + \text{null}\,(I_n \otimes B - B^{\mathrm{T}} \otimes I_n)).$$
Equality holds if and only if $m = n$ and A and B are similar.

10. Let $A \in F^{n\times n}$ and assume that $p_1(x), \ldots, p_k(x) \in F[x]$ are the nontrivial normalized invariant polynomials of $-A+xI$, where $p_1(x)|p_2(x)|\ldots|p_k(x)$ and $p_1(x)p_2(x)\ldots p_k(x)$ $=$ det $(xI-A)$. Then $A \approx C(p_1)\oplus C(p_2)\oplus\ldots\oplus C(p_k)$ and $C(p_1)\oplus C(p_2)\oplus\ldots\oplus C(p_k)$ is called the *rational canonical form* of A (cf. Section 6.7).
11. For $A, B \in \mathrm{H}(\Omega)^{n\times n}$, analytic similarity implies local similarity, local similarity implies point-wise similarity, and point-wise similarity implies rational similarity.
12. For $n = 1$, all the four concepts in Fact 11 are equivalent. For $n \geq 2$, local similarity, point-wise similarity, and rational similarity, are distinct (see Example 2).
13. The equivalence of the three matrices in Fact 6 over $\mathrm{H}(\Omega)$ implies the point-wise similarity of A and B.
14. Let $A, B \in \mathrm{H}_0^{n\times n}$. Then A and B are analytically similar over H_0 if and only if A and B are rationally similar over H_0 and there exists $\eta(A,A)+1$ matrices $T_0, \ldots, T_\eta \in \mathbb{C}^{n\times n}$ ($\eta = \eta(A,A)$), such that det $T_0 \neq 0$ and
$$\sum_{i=0}^{k} A_i T_{k-i} - T_{k-i}B_i = 0, \quad k = 0, \ldots, \eta(A,A).$$
15. Suppose that the characteristic polynomial of $A(x)$ splits over H_0:
$$\det(\lambda I - A(x)) = \prod_{i=1}^{n}(\lambda - \lambda_i(x)), \quad \lambda_i(x) \in \mathrm{H}_0,\ i = 1, \ldots, n.$$
Then $A(x)$ is analytically similar to
$$\begin{aligned}&C(x) = \oplus_{i=1}^{\ell} C_i(x), \quad C_i(x) \in \mathrm{H}_0^{n_i\times n_i},\\ &(\alpha_i I_{n_i} - C_i(0))^{n_i} = 0,\ \alpha_i = \lambda_{n_i}(0),\ \alpha_i \neq \alpha_j \quad \text{for} \quad i \neq j,\ i,j = 1, \ldots, \ell.\end{aligned}$$
16. Assume that the characteristic polynomial of $A(x) \in \mathrm{H}_0$ splits in H_0.Then $A(x)$ is analytically similar to a block diagonal matrix $C(x)$ of the form Fact 15 such that each $C_i(x)$ is an upper triangular matrix whose off-diagonal entries are polynomials in x. Moreover, the degree of each polynomial entry above the diagonal in the matrix $C_i(x)$ does not exceed $\eta(C_i, C_i)$ for $i = 1, \ldots, \ell$.
17. Let $P(x)$ and $Q(x)$ be matrices of the form
$$\begin{aligned}&P(x) = \oplus_{i=1}^{p} P_i(x),\ P_i(x) \in \mathrm{H}_0^{m_i\times m_i},\\ &(\alpha_i I_{m_i} - P_i(0))^{m_i} = 0,\ \alpha_i \neq \alpha_j \quad \text{for} \quad i \neq j, i,j = 1, \ldots, p,\\ &Q(x) = \oplus_{j=1}^{q} Q_j(x),\ Q_j(x) \in \mathrm{H}_0^{n_j\times n_j},\\ &(\beta_j I_{n_j} - Q_j(0))^{n_j} = 0,\ \beta_i \neq \beta_j \quad \text{for} \quad i \neq j,\ i,j = 1, \ldots, q.\end{aligned}$$
Assume furthermore that
$$\alpha_i = \beta_i,\ i = 1, \ldots, t,\ \alpha_j \neq \beta_j,\ i = t+1, \ldots, p,\ j = t+1, \ldots, q,\ 0 \leq t \leq \min(p,q).$$
Then the nonconstant local invariant polynomials of $I \otimes P(x) - Q(x)^{\mathrm{T}} \otimes I$ are the nonconstant local invariant polynomials of $I \otimes P_i(x) - Q_i(x)^{\mathrm{T}} \otimes I$ for $i = 1, \ldots, t$:
$$\mathcal{K}_p(P,Q) = \sum_{i=1}^{t} \mathcal{K}_p(P_i, Q_i), \quad p = 1, \ldots, .$$

In particular, if $C(x)$ is of the form in Fact 15, then

$$\eta(C, C) = \max_{1 \le i \le \ell} \eta(C_i, C_i).$$

18. $A(x)\overset{a}{\approx}B(x) \iff A(y^m)\overset{a}{\approx}B(y^m)$ for any $2 \le m \in \mathbb{N}$.
19. [GR65] (*Weierstrass preparation theorem*) For any monic polynomial $p(\lambda, x) = \lambda^n + \sum_{i=1}^{n} a_i(x)\lambda^{n-i} \in \mathrm{H}_0[\lambda]$ there exists $m \in \mathbb{N}$ such that $p(\lambda, y^m)$ splits over H_0.
20. For a given rational canonical form $A(x) \in \mathrm{H}_0^{2\times 2}$ there are at most a countable number of analytic similarity classes. (See Example 3.)
21. For a given rational canonical form $A(x) \in \mathrm{H}_0^{n\times n}$, where $n \ge 3$, there may exist a family of distinct similarity classes corresponding to a finite dimensional variety. (See Example 4.)
22. Let $A(x) \in H_0^{n\times n}$ and assume that the characteristic polynomial of $A(x)$ splits in H_0 as in Fact 15. Let $B(x) = \mathrm{diag}\,(\lambda_1(x), \ldots, \lambda_n(x))$. Then $A(x)$ and $B(x)$ are not analytically similar if and only if there exists a nonnegative integer p such that

    $$\begin{aligned} &\mathcal{K}_p(A, A) + \mathcal{K}_p(B, B) < 2\mathcal{K}_p(A, B),\\ &\mathcal{K}_j(A, A) + \mathcal{K}_j(B, B) = 2\mathcal{K}_j(A, B),\ j = 0, \ldots, p-1, \quad \text{if } p \ge 1. \end{aligned}$$

    In particular, $A(x)\overset{a}{\approx}B(x)$ if and only if the three matrices given in Fact 6 are equivalent over H_0.
23. [Fri78] Let $A(x) \in \mathbb{C}[x]^{n\times n}$. Then each eigenvalue $\lambda(x)$ of $A(x)$ is an algebraic function. Assume that $A(\zeta)$ is diagonalizable for some $\zeta \in \mathbb{C}$. Then the linear part of each branch of $\lambda_j(x)$ is linear at ζ, i.e., is of the form $\alpha + \beta x$ for some $\alpha, \beta \in \mathbb{C}$.
24. Let $A(x) \in \mathbb{C}[x]^{n\times n}$ be of the form $A(x) = \sum_{k=0}^{\ell} A_k x^k$, where $A_k \in \mathbb{C}^{n\times n}$ for $k = 0, \ldots, \ell$ and $\ell \ge 1$, $A_\ell \ne 0$. Then one of the following conditions implies that $A(x) = S(x)B(x)S^{-1}(x)$, where $S(x) \in \mathrm{GL}(n, \mathbb{C}[x])$ and $B(x) \in \mathbb{C}[x]^{n\times n}$ is a diagonal matrix of the form $\oplus_{i=1}^{m}\lambda_i(x)I_{k_i}$, where $k_1, \ldots, k_m \ge 1$. Furthermore, $\lambda_1(x), \ldots, \lambda_m(x)$ are m distinct polynomials satisfying the following conditions:

    (a) $\deg \lambda_1 = \ell \ge \deg \lambda_i(x), i = 2, \ldots, m-1$.

    (b) The polynomial $\lambda_i(x) - \lambda_j(x)$ has only simple roots in $\mathbb{C}$ for $i \ne j$. ($\lambda_i(\zeta) = \lambda_j(\zeta) \Rightarrow \lambda_i'(\zeta) \ne \lambda_j'(\zeta)$).

    - i. The characteristic polynomial of $A(x)$ splits in $\mathbb{C}[x]$, i.e., all the eigenvalues of $A(x)$ are polynomials. $A(x)$ is point-wise diagonalizable in $\mathbb{C}$ and no two distinct eigenvalues are tangent at any $\zeta \in \mathbb{C}$.
    - ii. $A(x)$ is point-wise diagonalizable in $\mathbb{C}$ and A_ℓ is diagonalizable. No two distinct eigenvalues are tangent at any point $\zeta \in \mathbb{C} \cup \{\infty\}$. Then $A(x)$ is strictly similar to $B(x)$, i.e., $S(x)$ can be chosen in $\mathrm{GL}(n, \mathbb{C})$. Furthermore, $\lambda_1(x), \ldots, \lambda_m(x)$ satisfy the additional condition:

    (c) For $i \ne j$, either $\frac{d^\ell \lambda_i}{d^\ell x}(0) \ne \frac{d^\ell \lambda_j}{d^\ell x}(0)$ or $\frac{d^\ell \lambda_i}{d^\ell x}(0) = \frac{d^\ell \lambda_j}{d^\ell x}(0)$ and $\frac{d^{\ell-1} \lambda_i}{d^{\ell=1} x}(0) \ne \frac{d^{\ell-1} \lambda_j}{d^{\ell-1} x}(0)$.

Examples:

1. Let

    $$A = \begin{bmatrix} 1 & 0 \\ 0 & 5 \end{bmatrix}, \ B = \begin{bmatrix} 1 & 1 \\ 0 & 5 \end{bmatrix} \in \mathbb{Z}^{2\times 2}.$$

    Then $A(x)$ and $B(x)$ have the same invariant polynomials over $\mathbb{Z}[x]$ and A and B are not similar over $\mathbb{Z}$.

2. Let
$$A(z) = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad D(z) = \begin{bmatrix} z & 0 \\ 0 & 1 \end{bmatrix}.$$
Then $zA(z) = D(z)A(z)D(z)^{-1}$, i.e., $A(z), zA(z)$ are rationally similar. Clearly $A(z)$ and $zA(z)$ are not point-wise similar for any Ω containing 0. Now $zA(z), z^2A(z)$ are point-wise similar in $\mathbb{C}$, but they are not locally similar on H_0.
3. Let $A(x) \in \mathrm{H}_0^{2\times 2}$ and assume that $\det(\lambda I - A(x)) = (\lambda - \lambda_1(x))(\lambda - \lambda_2(x))$. Then $A(x)$ is analytically similar either to a diagonal matrix or to
$$B(x) = \begin{bmatrix} \lambda_1(x) & x^k \\ 0 & \lambda_2(x) \end{bmatrix}, \quad k = 0, \ldots, p \ (p \geq 0).$$
Furthermore, if $A(x) \overset{a}{\approx} B(x)$, then $\eta(A, A) = k$.
4. Let $A(x) \in \mathrm{H}_0^{3\times 3}$. Assume that
$$A(x) \overset{r}{\approx} C(p), \quad p(\lambda, x) = \lambda(\lambda - x^{2m})(\lambda - x^{4m}), \quad m \geq 1.$$
Then $A(x)$ is analytically similar to a matrix
$$B(x, a) = \begin{bmatrix} 0 & x^{k_1} & a(x) \\ 0 & x^{2m} & x^{k_2} \\ 0 & 0 & x^{4m} \end{bmatrix}, \quad 0 \leq k_1, k_2 \leq \infty \ (x^\infty = 0),$$
where $a(x)$ is a polynomial of degree $4m - 1$ at most. Furthermore, $B(x, a) \overset{a}{\approx} B(x, b)$ if and only if the following:
   (a) If $a(0) \neq 1$, then $b - a$ is divisible by x^m.
   (b) If $a(0) = 1$ and $\frac{d^i a}{dx^i} = 0$, $i = 1, \ldots, k - 1$, $\frac{d^k a}{dx^k} \neq 0$ for $1 \leq k < m$, then $b - a$ is divisible by x^{m+k}.
   (c) If $a(0) = 1$ and $\frac{d^i a}{dx^i} = 0$, $i = 1, \ldots, m$, then $b - a$ is divisible by x^{2m}.

   Then for $k_1 = k_2 = m$ and $a(0) \in \mathbb{C}\backslash\{1\}$, we can assume that $a(x)$ is a polynomial of degree less than m. Furthermore, the similarity classes of $A(x)$ are uniquely determined by such $a(x)$. These similarity classes are parameterized by $\mathbb{C}\backslash\{1\} \times \mathbb{C}^{m-1}$ (the Taylor coefficients of $a(x)$).

33.2 Simultaneous Similarity of Matrices

In this section, we introduce the notion of simultaneous similarity of matrices over a domain $\mathbb{D}$. The problem of simultaneous similarity of matrices over a field F, i.e., to describe the similarity class of a given m (≥ 2) tuple of matrices or to decide when a given two tuples of matrices are simultaneously similar, is in general a hard problem, which will be discussed in the next sections. There are some cases where this problem has a relatively simple solution. As shown in the Facts, the problem of analytic similarity of $A(x), B(x) \in \mathrm{H}_0^{n\times n}$ reduces to the problem of simultaneously similarity of certain 2-tuples of matrices.

Definitions:

For $A_0, \ldots, A_l \in \mathbb{D}^{n\times n}$ denote by $\mathcal{A}(A_0, \ldots, A_l) \subset \mathbb{D}^{n\times n}$ the minimal algebra in $\mathbb{D}^{n\times n}$ containing I_n and $A_0, \ldots, A_l$. Thus, every matrix $G \in \mathcal{A}(A_0, \ldots, A_l)$ is a noncommutative polynomial in $A_0, \ldots, A_l$.

For $l \geq 1$, $(A_0, A_1, \ldots, A_\ell), (B_0, \ldots, B_\ell) \in (\mathbb{D}^{n\times n})^{\ell+1}$ are called **simultaneously** similar, denoted by $(A_0, A_1, \ldots, A_\ell) \approx (B_0, \ldots, B_\ell)$, if there exists $P \in \mathrm{GL}(n, \mathbb{D})$ such that $B_i = PA_iP^{-1}, i = 0, \ldots, \ell$, i.e., $(B_0, B_1, \ldots, B_\ell) = P(A_0, A_1, \ldots, A_\ell)P^{-1}$.

Associate with $(A_0, A_1, \ldots, A_\ell), (B_0, \ldots, B_\ell) \in (\mathbb{D}^{n\times n})^{\ell+1}$ the matrix polynomials $A(x) = \sum_{i=0}^{\ell} A_i x^i, B(x) = \sum_{i=0}^{\ell} B_i x^i \in \mathbb{D}[x]^{n\times n}$. $A(x)$ and $B(x)$ are called **strictly** similar ($A \overset{s}{\approx} B$) if there exists $P \in \mathrm{GL}(n, \mathbb{D})$ such that $B(x) = PA(x)P^{-1}$.

Facts:

1. $A \overset{s}{\approx} B \iff (A_0, A_1, \ldots, A_\ell) \approx (B_0, \ldots, B_\ell)$.
2. $(A_0, \ldots, A_\ell) \in (\mathbb{C}^{n\times n})^{\ell+1}$ is simultaneously similar to a diagonal tuple $(B_0, \ldots, B_\ell) \in (\mathbb{C}^{n\times n})^{\ell+1}$, i.e., each B_i is a diagonal matrix if and only if $A_0, \ldots, A_\ell$ are $\ell + 1$ commuting diagonalizable matrices: $A_iA_j = A_jA_i$ for $i, j = 0, \ldots, \ell$.
3. If $A_0, \ldots, A_\ell \in \mathbb{C}^{n\times n}$ commute, then $(A_0, \ldots, A_\ell)$ is simultaneously similar to an upper triangular tuple $(B_0, \ldots, B_\ell)$.
4. Let $l \in \mathbb{N}$, $(A_0, \ldots, A_l), (B_0, \ldots, B_l) \in (\mathbb{C}^{n\times n})^{l+1}$, and $U = [U_{ij}]_{i,j=1}^{l+1}, V = [V_{ij}]_{i,j=1}^{l+1}$, $W = [W_{ij}]_{i,j=1}^{l+1} \in \mathbb{C}^{n(l+1)\times n(l+1)}$, $U_{ij}, V_{ij}, W_{ij} \in \mathbb{C}^{n\times n}, i, j = 1, \ldots, l+1$ be block upper triangular matrices with the following block entries:

   $$U_{ij} = A_{j-i},\ V_{ij} = B_{j-i},\ W_{ij} = \delta_{(i+1)j} I_n, \quad i = 1, \ldots, l+1, j = i, \ldots, l+1.$$

   Then the system in Fact 33.1.14 is solvable with $T_0 \in \mathrm{GL}(n, \mathbb{C})$ if and only for $l = \kappa(A, A)$ the pairs (U, W) and (V, W) are simultaneously similar.
5. For $A_0, \ldots, A_\ell \in (\mathbb{C}^{n\times n})^{\ell+1}$ the following are equivalent:
   (a) $(A_0, \ldots, A_\ell)$ is simultaneously similar to an upper triangular tuple $(B_0, \ldots, B_\ell) \in (\mathbb{C}^{n\times n})^{\ell+1}$.
   (b) For any $0 \leq i < j \leq \ell$ and $M \in \mathcal{A}(A_0, \ldots, A_\ell)$, the matrix $(A_iA_j - A_jA_i)M$ is nilpotent.
6. Let $\mathcal{X}_0 = \mathcal{A}(A_0, \ldots, A_\ell) \subseteq F^{n\times n}$ and define recursively

   $$\mathcal{X}_k = \sum_{0\leq i<j\leq \ell} (A_iA_j - A_jA_i)\mathcal{X}_{k-1} \subseteq F^{n\times n}, \quad k = 1, \ldots .$$

   Then $(A_0, \ldots, A_\ell)$ is simultaneously similar to an upper triangular tuple if and only if the following two conditions hold:
   (a) $A_i\mathcal{X}_k \subseteq \mathcal{X}_k, \quad i = 0, \ldots, \ell,\ k = 0, \ldots .$
   (b) There exists $q \geq 1$ such that $\mathcal{X}_q = \{0\}$ and $\mathcal{X}_k$ is a strict subspace of $\mathcal{X}_{k-1}$ for $k = 1, \ldots, q$.

Examples:

1. This example illustrates the construction of the matrices U and W in Fact 4. Let $A_0 = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$, $A_1 = \begin{bmatrix} 5 & 6 \\ 7 & 8 \end{bmatrix}$, and $A_2 = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}$. Then

   $$U = \begin{bmatrix} 1 & 2 & 5 & 6 & 1 & -1 \\ 3 & 4 & 7 & 8 & -1 & 1 \\ 0 & 0 & 1 & 2 & 5 & 6 \\ 0 & 0 & 3 & 4 & 7 & 8 \\ 0 & 0 & 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 & 3 & 4 \end{bmatrix} \quad \text{and} \quad W = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

33.3 Property L

Property L was introduced and studied in [MT52] and [MT55]. In this section, we consider only square pencils $A(x) = A_0 + A_1 x \in \mathbb{C}[x]^{n\times n}, A(x_0, x_1) \in \mathbb{C}[x_0, x_1]^{n\times n}$, where $A_1 \neq 0$.

Definitions:

A pencil $A(x) \in \mathbb{C}[x]^{n\times n}$ has **property** L if all the eigenvalues of $A(x_0, x_1)$ are linear functions. That is, $\lambda_i(x_0, x_1) = \alpha_i x_0 + \beta_i x_1$ is an eigenvalue of $A(x_0, x_1)$ of multiplicity n_i for $i = 1, \ldots, m$, where

$$n = \sum_{i=1}^{m} n_i, \quad (\alpha_i, \beta_i) \neq (\alpha_j, \beta_j), \quad \text{for} \quad 1 \le i < j \le m.$$

A pencil $A(x) = A_0 + A_1 x$ is **Hermitian** if A^0, A^1 are Hermitian.

Facts:

Most of the results of this section can be found in [MF80], [Fri81], and [Fri].

1. For a pencil $A(x) = A_0 + xA_1 \in \mathbb{C}[x]^{n\times n}$ the following are equivalent:
   (a) $A(x)$ has property L.
   (b) The eigenvalues of $A(x)$ are polynomials of degree 1 at most.
   (c) The characteristic polynomial of $A(x)$ splits into linear factors over $\mathbb{C}[x]$.
   (d) There is an ordering of the eigenvalues of A_0 and A_1, $\alpha_1, \ldots, \alpha_n$ and $\beta_1, \ldots, \beta_n$, respectively, such that the eigenvalues of $A_0 x_0 + A_1 x_1$ are $\alpha_1 x_0 + \beta_1 x_1, \ldots, \alpha_n x_0 + \beta_n x_1$.
2. A pencil in $A(x)$ has property L if one of the following conditions hold:
   (a) $A(x)$ is similar over $\mathbb{C}(x)$ to an upper triangular matrix $U(x) \in \mathbb{C}(x)^{n\times n}$.
   (b) $A(x)$ is strictly similar to an upper triangular pencil $U(x) = U_0 + U_1 x$.
   (c) $A(x)$ is similar over $\mathbb{C}[x]$ to a diagonal matrix $B(x) \in \mathbb{C}[x]^{n\times n}$.
   (d) $A(x)$ is strictly similar to a diagonal pencil.
3. If a pencil $A(x_0, x_1)$ has property L, then any two distinct eigenvalues are not tangent at any point of $\mathbb{C} \cup \infty$.
4. Assume that $A(x)$ is point-wise diagonalizable on $\mathbb{C}$. Then $A(x)$ has property L. Furthermore, $A(x)$ is similar over $\mathbb{C}[x]$ to a diagonal pencil $B(x) = B_0 + B_1 x$. Suppose furthermore that A_1 is diagonalizable, i.e., $A(x_0, x_1)$ is point-wise diagonalizable on $\mathbb{C}^2$. Then $A(x)$ is strictly similar to a diagonal pencil $B(x)$, i.e., A_0 and A_1 are commuting diagonalizable matrices.
5. Let $A(x) = A_0 + A_1 x \in \mathbb{C}[x]^{n\times n}$ such that A_1 and A_2 are diagonalizable and $A_0 A_1 \neq A_1 A_0$. Then exactly one of the following conditions hold:
   (a) $A(x)$ is not diagonalizable exactly at the points $\zeta_1, \ldots, \zeta_p$, where $1 \le p \le n(n-1)$.
   (b) For $n \ge 3$, $A(x) \in \mathbb{C}[x]^{n\times n}$ is diagonalizable exactly at the points $\zeta_1 = 0, \ldots, \zeta_q$ for some $q \ge 1$. (*We do not know if this condition is satisfied for some pencil.*)
6. Let $A(x) = A_0 + A_1 x$ be a Hermitian pencil satisfying $A_0 A_1 \neq A_1 A_0$. Then there exists $2q$ distinct complex points $\zeta_1, \overline{\zeta}_1 \ldots, \zeta_q, \overline{\zeta}_q \in \mathbb{C} \backslash \mathbb{R}$, $1 \le q \le \frac{n(n-1)}{2}$ such that $A(x)$ is not diagonalizable if and only if $x \in \{\zeta_1, \overline{\zeta}_1, \ldots, \zeta_q, \overline{\zeta}_q\}$.

Examples:

1. This example illustrates the case $n = 2$ of Fact 5. Let

$$A_0 = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \quad \text{and} \quad A_1 = \begin{bmatrix} 1 & 3 \\ -3 & 1 \end{bmatrix}, \quad \text{so} \quad A(x) = \begin{bmatrix} x+1 & 3x \\ -3x & x+2 \end{bmatrix}.$$

For $\zeta \in \mathbb{C}$, the only possible way $A(\zeta)$ can fail to be diagonalizable is if $A(\zeta)$ has repeated eigenvalues. The eigenvalues of $A(\zeta)$ are $\frac{1}{2}\left(2\zeta - \sqrt{1-36\zeta^2}+3\right)$ and $\frac{1}{2}\left(2\zeta + \sqrt{1-36\zeta^2}+3\right)$, so the only values of ζ at which it is possible that $A(\zeta)$ is not diagonalizable are $\zeta = \pm\frac{1}{6}$, and in fact $A(\pm\frac{1}{6})$ is not diagonalizable.

33.4 Simultaneous Similarity Classification I

This section outlines the setting for the classification of conjugacy classes of $l+1$ tuples $(A_0, A_1, \ldots, A_l) \in (\mathbb{C}^{n\times n})^{l+1}$ under the simultaneous similarity. This classification depends on certain standard notions in algebraic geometry that are explained briefly in this section. A detailed solution to the classification of conjugacy classes of $l+1$ tuples is outlined in the next section.

Definitions:

$\mathcal{X} \subset \mathbb{C}^N$ is called an **affine algebraic variety** (called here a **variety**) if it is the zero set of a finite number of polynomial equations in $\mathbb{C}^N$.

$\mathcal{X}$ is irreducible if $\mathcal{X}$ does not decompose in a nontrivial way to a union of two varieties.

If $\mathcal{X}$ is a finite nontrivial union of irreducible varieties, these irreducible varieties are called the **irreducible** components of $\mathcal{X}$.

$x \in \mathcal{X}$ is called a **regular** (**smooth**) point of irreducible $\mathcal{X}$ if in the neighborhood of this point $\mathcal{X}$ is a complex manifold of a fixed dimension d, which is called the **dimension** of $\mathcal{X}$ and is denoted by dim $\mathcal{X}$. $\emptyset$ is an irreducible variety of dimension -1.

For a reducible variety $\mathcal{Y} \subset \mathbb{C}^N$, the **dimension** of $\mathcal{Y}$, denoted by dim $\mathcal{Y}$, is the maximum dimension of its irreducible components.

The set of singular (nonsmooth) points of $\mathcal{X}$ is denoted by $\mathcal{X}_s$.

A set $\mathcal{Z}$ is a **quasi-irreducible** variety if there exists a nonempty irreducible variety $\mathcal{X}$ and a strict subvariety $\mathcal{Y} \subset \mathcal{X}$ such that $\mathcal{Z} = \mathcal{X}\backslash\mathcal{Y}$. The dimension of $\mathcal{Z}$, denoted by dim $\mathcal{Z}$, is defined to be equal to the dimension of $\mathcal{X}$.

A quasi-irreducible variety $\mathcal{Z}$ is **regular** if $\mathcal{Z} \subset \mathcal{X}\backslash\mathcal{X}_s$.

A **stratification** of $\mathbb{C}^N$ is a decomposition of $\mathbb{C}^N$ to a finite disjoint union of $\mathcal{X}_1, \ldots, \mathcal{X}_p$ of regular quasi-irreducible varieties such that Cl $(\mathcal{X}_i)\backslash\mathcal{X}_i = \cup_{j\in\mathcal{A}_i}\mathcal{X}_j$ for some $\mathcal{A}_i \subset \{1, \ldots, p\}$ for $i = 1, \ldots, p$. (Cl $(\mathcal{X}_i) = \mathcal{X}_i \iff \mathcal{A}_i = \emptyset$.)

Denote by $\mathbb{C}[\mathbb{C}^N]$ the ring of polynomial in N variables with coefficients in $\mathbb{C}$.

Denote by $\mathcal{W}_{n,l+1,r+1}$ the finite dimensional vector space of multilinear polynomials in $(l+1)n^2$ variables of degree at most $r+1$. That is, the degree of each variable in any polynomial is at most 1. $N(n,l,r) :=$ dim $\mathcal{W}_{n,l+1,r+1}$. $\mathcal{W}_{n,l+1,r+1}$ has a standard basis $\mathbf{e}_1, \ldots, \mathbf{e}_{N(n,l,r)}$ in $\mathcal{W}_{n,l+1,r+1}$ consisting of monomials in $(l+1)n^2$ variables of degree $r+1$ at most, arranged in a lexicographical order.

Let $\mathcal{X} \subset \mathbb{C}^N$ be a quasi-irreducible variety. Denote by $\mathbb{C}[\mathcal{X}]$ the restriction of all polynomials $f(x) \in \mathbb{C}[\mathbb{C}^N]$ to $\mathcal{X}$, where $f, g \in \mathbb{C}[\mathbb{C}^N]$ are identified if $f - g$ vanishes on $\mathcal{X}$. Let $\mathbb{C}(\mathcal{X})$ denote the quotient field of $\mathbb{C}[\mathcal{X}]$.

A rational function $h \in \mathbb{C}(\mathcal{X})$ is **regular** if h is defined everywhere in $\mathcal{X}$. A regular rational function on $\mathcal{X}$ is an analytic function.

Denote by $\mathbf{A}$ the $l+1$ tuple $(A_0, \ldots, A_l) \in (\mathbb{C}^{n\times n})^{l+1}$. The group GL$(n, \mathbb{C})$ acts by conjugation on $(\mathbb{C}^{n\times n})^{l+1}$: $T\mathbf{A}T^{-1} = (TA_0T^{-1}, \ldots TA_lT^{-1})$ for any $\mathbf{A} \in (\mathbb{C}^{n\times n})^{l+1}$ and $T \in$ GL$(n, \mathbb{C})$.

Let orb $(\mathbf{A}) := \{T\mathbf{A}T^{-1} : T \in \mathrm{GL}(n,\mathbb{C})\}$ be the **orbit** of $\mathbf{A}$ (under the action of $\mathrm{GL}(n,\mathbb{C})$).

Let $\mathcal{X} \subset (\mathbb{C}^{n\times n})^{l+1}$ be a quasi-irreducible variety. $\mathcal{X}$ is called **invariant** (under the action of $\mathrm{GL}(n,\mathbb{C})$) if $T\mathcal{X}T^{-1} = \mathcal{X}$ for all $T \in \mathrm{GL}(n,\mathbb{C})$.

Assume that $\mathcal{X}$ is an invariant quasi-irreducible variety. A rational function $h \in \mathbb{C}(\mathcal{X})$ is called **invariant** if h is the same value on any two points of a given orbit in $\mathcal{X}$, where h is defined. Denote by $\mathbb{C}[\mathcal{X}]^{\mathrm{inv}} \subseteq \mathbb{C}[\mathcal{X}]$ and $\mathbb{C}(\mathcal{X})^{\mathrm{inv}} \subseteq \mathbb{C}(\mathcal{X})$ the subdomain of invariant polynomials and subfield of invariant functions, respectively.

Facts:

For general background, consult for example [Sha77]. More specific details are given in [Fri83], [Fri85], and [Fri86].

1. An intersection of a finite or infinite number of varieties is a variety, which can be an empty set.
2. A finite union of varieties in $\mathbb{C}^N$ is a variety.
3. Every variety $\mathcal{X}$ is a finite nontrivial union of irreducible varieties.
4. Let $\mathcal{X} \subset \mathbb{C}^N$ be an irreducible variety. Then $\mathcal{X}$ is path-wise connected.
5. $\mathcal{X}_s$ is a proper subvariety of the variety $\mathcal{X}$ and $\dim \mathcal{X}_s < \dim \mathcal{X}$.
6. $\dim \mathbb{C}^N = N$ and $(\mathbb{C}^N)_s = \emptyset$. For any $\mathbf{z} \in \mathbb{C}^N$, the set $\{\mathbf{z}\}$ is an irreducible variety of dimension 0.
7. A quasi-irreducible variety $\mathcal{Z} = \mathcal{X}\backslash\mathcal{Y}$ is path-wise connected and its closure, denoted by Cl $(\mathcal{Z})$, is equal to $\mathcal{X}$. Cl $(\mathcal{Z})\backslash\mathcal{Z}$ is a variety of dimension strictly less than the dimension of $\mathcal{Z}$.
8. The set of all regular points of an irreducible variety $\mathcal{X}$, denoted by $\mathcal{X}_r := \mathcal{X}\backslash\mathcal{X}_s$, is a quasi-irreducible variety. Moreover, $\mathcal{X}_r$ is a path-wise connected complex manifold of complex dimension $\dim \mathcal{X}$.
9. $N(n,l,r) := \dim \mathcal{W}_{n,l+1,r+1} = \sum_{i=0}^{r+1} \binom{(l+1)n^2}{i}$.
10. For an irreducible $\mathcal{X}$, $\mathbb{C}[\mathcal{X}]$ is an integral domain.
11. For a quasi-irreducible $\mathcal{X}$, $\mathbb{C}[\mathcal{X}], \mathbb{C}(\mathcal{X})$ can be identified with $\mathbb{C}[\mathrm{Cl}\,(\mathcal{X})], \mathbb{C}(\mathrm{Cl}\,(\mathcal{X}))$, respectively.
12. For $\mathbf{A} \in (\mathbb{C}^{n\times n})^{l+1}$, orb $(\mathbf{A})$ is a quasi-irreducible variety in $(\mathbb{C}^{n\times n})^{l+1}$.
13. Let $\mathcal{X} \subset (\mathbb{C}^{n\times n})^{l+1}$ be a quasi-irreducible variety. $\mathcal{X}$ is invariant if $\mathbf{A} \in \mathcal{X} \iff$ orb $(\mathbf{A}) \subseteq \mathcal{X}$.
14. Let $\mathcal{X}$ be an invariant quasi-irreducible variety. The quotient field of $\mathbb{C}[\mathcal{X}]^{\mathrm{inv}}$ is a subfield of $\mathbb{C}(\mathcal{X})^{\mathrm{inv}}$, and in some interesting cases the quotient field of $\mathbb{C}[\mathcal{X}]^{\mathrm{inv}}$ is a strict subfield of $\mathbb{C}(\mathcal{X})^{\mathrm{inv}}$.
15. Assume that $\mathcal{X} \subset (\mathbb{C}^{n\times n})^{l+1}$ is an invariant quasi-irreducible variety. Then $\mathbb{C}[\mathcal{X}]^{\mathrm{inv}}$ and $\mathbb{C}(\mathcal{X})^{\mathrm{inv}}$ are finitely invariant generated. That is, there exists $f_1, \ldots, f_i \in \mathbb{C}[\mathcal{X}]^{\mathrm{inv}}$ and $g_1, \ldots, g_j \in \mathbb{C}(\mathcal{X})^{\mathrm{inv}}$ such that any polynomial in $\mathbb{C}[\mathcal{X}]^{\mathrm{inv}}$ is a polynomial in $f_1, \ldots, f_i$, and any rational function in $\mathbb{C}(\mathcal{X})^{\mathrm{inv}}$ is a rational function in $g_1, \ldots, g_j$.
16. (*Classification Theorem*) Let $n \geq 2$ and $l \geq 0$ be fixed integers. Then there exists a stratification $\cup_{i=1}^{p} \mathcal{X}_i$ of $(\mathbb{C}^{n\times n})^{l+1}$ with the following properties. For each $\mathcal{X}_i$ there exist m_i regular rational functions $g_{1,i}, \ldots, g_{m_i,i} \in \mathbb{C}(\mathcal{X}_i)^{\mathrm{inv}}$ such that the values of $g_{j,i}$ for $j = 1, \ldots, m_i$ on any orbit in $\mathcal{X}_i$ determines this orbit uniquely.
    The rational functions $g_{1,i}, \ldots, g_{m_i,i}$ are the generators of $\mathbb{C}(\mathcal{X}_i)^{\mathrm{inv}}$ for $i = 1, \ldots, p$.

Examples:

1. Let $\mathcal{S}$ be an irreducible variety of scalar matrices $\mathcal{S} := \{A \in \mathbb{C}^{2\times 2} : A = \frac{\mathrm{tr}\,A}{2} I_2\}$ and $\mathcal{X} := \mathbb{C}^{2\times 2}\backslash\mathcal{S}$ be a quasi-irreducible variety. Then $\dim \mathcal{X} = 4$, $\dim \mathcal{S} = 1$, and $\mathbb{C}^{2\times 2} = \mathcal{X} \cup \mathcal{S}$ is a stratification of $\mathbb{C}^{2\times 2}$.
2. Let $\mathcal{U} \subset (\mathbb{C}^{2\times 2})^2$ be the set of all pairs $(A, B) \in (\mathbb{C}^{2\times 2})^2$, which are simultaneously similar

to a pair of upper triangular matrices. Then $\mathcal{U}$ is a variety given by the zero of the following polynomial:

$$\mathcal{U} := \{(A, B) \in (\mathbb{C}^{2\times 2})^2 : (2\operatorname{tr} A^2 - (\operatorname{tr} A)^2)(2\operatorname{tr} B^2 - (\operatorname{tr} B)^2) - (2\operatorname{tr} AB - \operatorname{tr} A \operatorname{tr} B)^2 = 0\}.$$

Let $\mathcal{C} \subset \mathcal{U}$ be the variety of commuting matrices:

$$\mathcal{C} := \{(A, B) \in (\mathbb{C}^{2\times 2})^2 : AB - BA = 0\}.$$

Let $\mathcal{V}$ be the variety given by the zeros of the following three polynomials:

$$\mathcal{V} := \{(A, B) \in (\mathbb{C}^{2\times 2})^2 : 2\operatorname{tr} A^2 - (\operatorname{tr} A)^2 = 2\operatorname{tr} B^2 - (\operatorname{tr} B)^2 = 2\operatorname{tr} AB - \operatorname{tr} A \operatorname{tr} B = 0\}.$$

Then $\mathcal{V}$ is the variety of all pairs (A, B), which are simultaneously similar to a pair of the form $\left(\begin{bmatrix} \lambda & \alpha \\ 0 & \lambda \end{bmatrix}, \begin{bmatrix} \mu & \beta \\ 0 & \mu \end{bmatrix}\right)$. Hence, $\mathcal{V} \subset \mathcal{C}$. Let $\mathcal{W} := \{A \in (\mathbb{C}^{2\times 2}) : \ 2\operatorname{tr} A^2 - (\operatorname{tr} A)^2 = 0\}$ and $\mathcal{S} \subset \mathcal{W}$ be defined as in the previous example. Define the following quasi-irreducible varieties in $(\mathbb{C}^{2\times 2})^2$:

$$\begin{aligned} &\mathcal{X}_1 := (\mathbb{C}^{2\times 2})^2 \backslash \mathcal{U},\ \mathcal{X}_2 := \mathcal{U} \backslash \mathcal{C},\ \mathcal{X}_3 = \mathcal{C} \backslash \mathcal{V},\ \mathcal{X}_4 := \mathcal{V} \backslash (\mathcal{S} \times \mathcal{W} \cup \mathcal{W} \times \mathcal{S}), \\ &\mathcal{X}_5 := \mathcal{S} \times (\mathcal{W} \backslash \mathcal{S}),\ \mathcal{X}_6 := (\mathcal{W} \backslash \mathcal{S}) \times \mathcal{S},\ \mathcal{X}_7 = \mathcal{S} \times \mathcal{S}. \end{aligned}$$

Then

$$\begin{aligned} &\dim \mathcal{X}_1 = 8,\ \dim \mathcal{X}_2 = 7,\ \dim \mathcal{X}_3 = 6,\ \dim \mathcal{X}_4 = 5, \\ &\dim \mathcal{X}_5 = \dim \mathcal{X}_6 = 4,\ \dim \mathcal{X}_7 = 2, \end{aligned}$$

and $\cup_{i=1}^{7} \mathcal{X}_i$ is a stratification of $(\mathbb{C}^{2\times 2})^2$.

3. In the classical case of similarity classes in $\mathbb{C}^{n\times n}$, i.e., $l = 0$, it is possible to choose a fixed set of polynomial invariant functions as $g_j(A) = \operatorname{tr}(A^j)$ for $j = 1, \ldots, n$. However, we still have to stratify $\mathbb{C}^{n\times n}$ to $\cup_{i=1}^{p} \mathcal{X}_i$, where each $A \in \mathcal{X}_i$ has some specific Jordan structures.
4. Consider the stratification $\mathbb{C}^{2\times 2} = \mathcal{X} \cup \mathcal{S}$ as in Example 1. Clearly $\mathcal{X}$ and $\mathcal{S}$ are invariant under the action of $\mathrm{GL}(2, \mathbb{C})$. The invariant functions $\operatorname{tr} A, \operatorname{tr} A^2$ determine uniquely orb (A) on $\mathcal{X}$. The Jordan canonical form of any A in $\mathcal{X}$ consists of two distinct Jordan blocks of order 1 or one Jordan block of order 2. The invariant function $\operatorname{tr} A$ determines orb (A) for any $A \in \mathcal{S}$. It is possible to refine the stratification of $\mathbb{C}^{2\times 2}$ to three invariant components $\mathbb{C}^{2\times 2} \backslash \mathcal{W}, \mathcal{W} \backslash \mathcal{S}, \mathcal{S}$, where $\mathcal{W}$ is defined in Example 2. Each component contains only matrices with one kind of Jordan block. On the first component, $\operatorname{tr} A, \operatorname{tr} A^2$ determine the orbit, and on the second and third component, $\operatorname{tr} A$ determines the orbit.
5. To see the fundamental difference between similarity ($l = 0$) and simultaneous similarity $l \geq 1$, it suffices to consider Example 2. Observe first that the stratification of $(\mathbb{C}^{2\times 2})^2 = \cup_{i=1}^{7} \mathcal{X}_i$ is invariant under the action of $\mathrm{GL}(2, \mathbb{C})$. On $\mathcal{X}_1$ the five invariant polynomials $\operatorname{tr} A$, $\operatorname{tr} A^2$, $\operatorname{tr} B$, $\operatorname{tr} B^2$, $\operatorname{tr} AB$, which are algebraically independent, determine uniquely any orbit in $\mathcal{X}_1$.

   Let $(A = [a_{ij}], B = [b_{ij}]) \in \mathcal{X}_2$. Then A and B have a unique one-dimensional common eigenspace corresponding to the eigenvalues λ_1, μ_1 of A, B, respectively. Assume that $a_{12}b_{21} - a_{21}b_{12} \neq 0$. Define

$$\begin{aligned} \lambda_1 &= \alpha(A, B) := \frac{(b_{11} - b_{22})a_{12}a_{21} + a_{22}a_{12}b_{21} - a_{11}a_{21}b_{12}}{a_{12}b_{21} - a_{21}b_{12}}, \\ \mu_1 &= \alpha(B, A). \end{aligned}$$

Then $\operatorname{tr} A,\ \operatorname{tr} B,\ \alpha(A, B),\ \alpha(B, A)$ are regular, algebraically independent, rational invariant functions on $\mathcal{X}_2$, whose values determine orb (A, B). Cl (orb (A, B)) contains an orbit generated by two diagonal matrices diag (λ_1, λ_2) and diag (μ_1, μ_2). Hence, $\mathbb{C}[\mathcal{X}_2]^{\mathrm{inv}}$ is generated by the five invariant polynomials $\operatorname{tr} A$, $\operatorname{tr} A^2$, $\operatorname{tr} B$, $\operatorname{tr} B^2$, $\operatorname{tr} AB$, which are algebraically dependent. Their values coincide exactly on two distinct orbits in $\mathcal{X}_2$. On $\mathcal{X}_3$ the previous invariant polynomials separate the orbits.

Any $(A=[a_{ij}], B=[b_{ij}]) \in \mathcal{X}_4$ is simultaneously similar to a unique pair of the form $\left(\begin{bmatrix} \lambda & 1 \\ 0 & \lambda \end{bmatrix}, \begin{bmatrix} \mu & t \\ 0 & \mu \end{bmatrix}\right)$. Then $t = \gamma(A,B) := \frac{b_{12}}{a_{12}}$. Thus, $\operatorname{tr} A, \operatorname{tr} B, \gamma(A,B)$ are three algebraically independent regular rational invariant functions on $\mathcal{X}_4$, whose values determine a unique orbit in $\mathcal{X}_4$. Clearly $(\lambda I_2, \mu I_2) \in \operatorname{Cl}(X_4)$. Then $\mathbb{C}[\mathcal{X}_4]^{\text{inv}}$ is generated by $\operatorname{tr} A, \operatorname{tr} B$. The values of $\operatorname{tr} A = 2\lambda, \operatorname{tr} B = 2\mu$ correspond to a complex line of orbits in $\mathcal{X}_4$. Hence, the classification problem of simultaneous similarity classes in $\mathcal{X}_4$ or $\mathcal{V}$ is a *wild* problem.

On $\mathcal{X}_5$, $\mathcal{X}_6$, $\mathcal{X}_7$, the algebraically independent functions $\operatorname{tr} A, \operatorname{tr} B$ determine the orbit in each of the stratum.

33.5 Simultaneous Similarity Classification II

In this section, we give an invariant stratification of $(\mathbb{C}^{n\times n})^{l+1}$, for $l \geq 1$, under the action of $\mathrm{GL}(n,\mathbb{C})$ and describe a set of invariant regular rational functions on each stratum, which separate the orbits up to a finite number. We assume the nontrivial case $n > 1$. It is conjectured that the continuous invariants of the given orbit determine uniquely the orbit on each stratum given in the Classification Theorem.

Classification of simultaneous similarity classes of matrices is a known *wild* problem [GP69]. For another approach to classification of simultaneous similarity classes of matrices using *Belitskii* reduction, see [Ser00]. See other applications of these techniques to classifications of linear systems [Fri85] and to canonical forms [Fri86].

Definitions:

For $\mathbf{A} = (A_0,\ldots,A_l), \mathbf{B} = (B_0,\ldots,B_l) \in (\mathbb{C}^{n\times n})^{l+1}$ let $L(\mathbf{B},\mathbf{A}) : \mathbb{C}^{n\times n} \to (\mathbb{C}^{n\times n})^{l+1}$ be the linear operator given by $U \mapsto (B_0U - UA_0, \ldots, B_lU - UA_l)$. Then $L(\mathbf{B},\mathbf{A})$ is represented by the $(l+1)n^2 \times n^2$ matrix $(I_n \otimes B_0^{\mathrm{T}} - A_0 \otimes I_n, \ldots, I_n \otimes B_l^{\mathrm{T}} - A_l \otimes I_n)^{\mathrm{T}}$, where $U \mapsto (I_n \otimes B_0^{\mathrm{T}} - A_0 \otimes I_n, \ldots, I_n \otimes B_l^{\mathrm{T}} - A_l \otimes I_n)^{\mathrm{T}} U$. Let $L(\mathbf{A}) := L(\mathbf{A},\mathbf{A})$. The dimension of $\operatorname{orb}(\mathbf{A})$ is denoted by $\dim \operatorname{orb}(\mathbf{A})$.

Let $\mathcal{S}_n := \{A \in \mathbb{C}^{n\times n} : A = \frac{\operatorname{tr} A}{n} I_n\}$ be the variety of scalar matrices. Let

$$\mathcal{M}_{n,l+1,r} := \{\mathbf{A} \in (\mathbb{C}^{n\times n})^{l+1} : \operatorname{rank}\ L(\mathbf{A}) = r\}, \quad r = 0,1,\ldots,n^2-1.$$

Facts:

Most of the results in this section are given in [Fri83].

1. For $\mathbf{A} = (A_0,\ldots,A_l), \in (\mathbb{C}^{n\times n})^{l+1}$, $\dim \operatorname{orb}(\mathbf{A})$ is equal to the rank of $L(\mathbf{A})$.
2. Since any $U \in \mathcal{S}_n$ commutes with any $B \in \mathbb{C}^{n\times n}$ it follows that $\ker L(\mathbf{A}) \supset \mathcal{S}_n$. Hence, $\operatorname{rank}\ L(\mathbf{A}) \leq n^2 - 1$.
3. $\mathcal{M}_{n,l+1,n^2-1}$ is an invariant quasi-irreducible variety of dimension $(l+1)n^2$, i.e., $\operatorname{Cl}(\mathcal{M}_{n,l+1,n^2-1}) = (\mathbb{C}^{n\times n})^{l+1}$. The sets $\mathcal{M}_{n,l+1,r}, r = n^2-2,\ldots,0$ have the decomposition to invariant quasi-irreducible varieties, each of dimension strictly less than $(l+1)n^2$.
4. Let $r \in [0, n^2-1]$, $\mathbf{A} \in \mathcal{M}_{n,l+1,r}$, and $\mathbf{B} = T\mathbf{A}T^{-1}$. Then $L(\mathbf{B},\mathbf{A}) = \operatorname{diag}(I_n \otimes T, \ldots, I_n \otimes T) L(\mathbf{A}) (I_n \otimes T^{-1})$, $\operatorname{rank}\ L(\mathbf{B},\mathbf{A}) = r$ and $\det L(\mathbf{B},\mathbf{A})[\alpha,\beta] = 0$ for any $\alpha \in \mathrm{Q}_{r+1,(l+1)n^2}, \beta \in \mathrm{Q}_{r+1,n^2}$. (See Section 32.2)
5. Let $\mathbf{X} = (X_0,\ldots,X_l) \in (\mathbb{C}^{n\times n})^{l+1}$ with the indeterminate entries $X_k = [x_{k,ij}]$ for $k = 0,\ldots,l$. Each $\det L(\mathbf{X},\mathbf{A})[\alpha,\beta], \alpha \in \mathrm{Q}_{r+1,(l+1)n^2}, \beta \in \mathrm{Q}_{r+1,n^2}$ is a vec-

tor in $\mathcal{W}_{n,l+1,r+1}$, i.e., it is a multilinear polynomial in $(l+1)n^2$ variables of degree $r+1$ at most. We identify $\det L(\mathbf{X},\mathbf{A})[\alpha,\beta], \alpha \in \mathrm{Q}_{r+1,(l+1)n^2}, \beta \in \mathrm{Q}_{r+1,n^2}$ with the **row** vector $\mathbf{a}(\mathbf{A},\alpha,\beta) \in \mathbb{C}^{N(n,l,r)}$ given by its coefficients in the basis $\mathbf{e}_1,\ldots,\mathbf{e}_{N(n,l,r)}$. The number of these vectors is $M(n,l,r) := \binom{(l+1)n^2}{r+1}\binom{n^2}{r+1}$. Let $R(\mathbf{A}) \in \mathbb{C}^{M(n,l,r)N(n,l,r)\times M(n,l,r)N(n,l,r)}$ be the matrix with the rows $\mathbf{a}(A,\alpha,\beta)$, where the pairs $(\alpha,\beta) \in \mathrm{Q}_{r+1,(l+1)n^2} \times \mathrm{Q}_{r+1,n^2}$ are listed in a lexicographical order.

6. All points on the orb $(\mathbf{A})$ satisfy the following polynomial equations in $\mathbb{C}[(\mathbb{C}^{n\times n})^{l+1}]$:

$$\begin{aligned}&\det L(\mathbf{X},\mathbf{A})[\alpha,\beta] = 0,\\ &\text{for all } \alpha \in \mathrm{Q}_{r+1,(l+1)n^2}, \beta \in \mathrm{Q}_{r+1,n^2}.\end{aligned} \tag{33.1}$$

   Thus, the matrix $R(\mathbf{A})$ determines the above variety.
7. If $\mathbf{B} = T\mathbf{A}T^{-1}$, then $R(\mathbf{A})$ is row equivalent to $R(\mathbf{B})$. To each orb $(\mathbf{A})$ we can associate a unique reduced row echelon form $F(\mathbf{A}) \in \mathbb{C}^{M(n,l,r)N(n,l,r)\times M(n,l,r)N(n,l,r)}$ of $R(\mathbf{A})$. $\varrho(\mathbf{A}) :=$ rank $R(\mathbf{A})$ is the number of linearly independent polynomials given in Eq. (33.1). Let $\mathcal{I}(\mathbf{A}) = \{(1,j_1),\ldots,(\varrho(\mathbf{A}),j_{\varrho(\mathbf{A})})\} \subset \{1,\ldots,\varrho(\mathbf{A})\}\times\{1,\ldots,N(n,l,r)\}$ be the location of the pivots in the $M(n,l,r) \times N(n,l,r)$ matrix $F(\mathbf{A}) = [f_{ij}(\mathbf{A})]$. That is, $1 \le j_1 < \ldots < j_{\varrho(\mathbf{A})} \le N(n,l,r)$, $f_{ij_i}(\mathbf{A}) = 1$ for $i = 1,\ldots,\varrho(\mathbf{A})$ and $f_{ij} = 0$ unless $j \ge i$ and $i \in [1,\varrho(\mathbf{A})]$. The nontrivial entries $f_{ij}(\mathbf{A})$ for $j > i$ are rational functions in the entries of the $l+1$ tuple $\mathbf{A}$. Thus, $F(\mathbf{B}) = F(\mathbf{A})$ for $\mathbf{B} \in$ orb $(\mathbf{A})$. The numbers $r(\mathbf{A}) :=$ rank $L(\mathbf{A})$, $\varrho(\mathbf{A})$ and the set $\mathcal{I}(\mathbf{A})$ are called the **discrete** invariants of orb $(\mathbf{A})$. The rational functions $f_{ij}(\mathbf{A}), i = 1,\ldots,\varrho(\mathbf{A}), j = i+1,\ldots,N(n,l,r)$ are called the **continuous** invariants of orb $(\mathbf{A})$.
8. (*Classification Theorem for Simultaneous Similarity)* Let $l \ge 1, n \ge 2$ be integers. Fix an integer $r \in [0,n^2-1]$ and let $M(n,l,r), N(n,l,r)$ be the integers defined as above. Let $0 \le \varrho \le \min(M(n,l,r),N(n,l,r))$ and the set $\mathcal{I} = \{(1,j_1),\ldots,(\varrho,j_\varrho) \subset \{1,\ldots,\varrho\} \times \{1,\ldots,N(n,l,r)\}, 1 \le j_1 < \ldots < j_\varrho \le N(n,l,r)$ be given. Let $\mathcal{M}_{n,l+1.r}(\varrho,\mathcal{I})$ be the set of all $\mathbf{A} \in (\mathbb{C}^{n\times n})^{l+1}$ such that rank $L(\mathbf{A}) = r$, $\varrho(\mathbf{A}) = \varrho$, and $\mathcal{I}(\mathbf{A}) = \mathcal{I}$. Then $\mathcal{M}_{n,l+1.r}(\varrho,\mathcal{I})$ is invariant quasi-irreducible variety under the action of $\mathrm{GL}(n,\mathbb{C})$. Suppose that $\mathcal{M}_{n,l+1.r}(\varrho,\mathcal{I}) \ne \emptyset$. Recall that for each $\mathbf{A} \in \mathcal{M}_{n,l+1.r}(\varrho,\mathcal{I})$ the continuous invariants of $\mathbf{A}$, which correspond to the entries $f_{ij}(\mathbf{A}),\ i = 1,\ldots,\varrho,\ j = i+1,\ldots,N(n,l,r)$ of the reduced row echelon form of $R(\mathbf{A})$, are regular rational invariant functions on $\mathcal{M}_{n,l+1.r}(\varrho,\mathcal{I})$. Then the values of the continuous invariants determine a finite number of orbits in $\mathcal{M}_{n,l+1.r}(\varrho,\mathcal{I})$.

   The quasi-irreducible variety $\mathcal{M}_{n,l+1.r}(\varrho,\mathcal{I})$ decomposes uniquely as a finite union of invariant regular quasi-irreducible varieties. The union of all these decompositions of $\mathcal{M}_{n,l+1.r}(\varrho,\mathcal{I})$ for all possible values r,ϱ, and the sets $\mathcal{I}$ gives rise to an invariant stratification of $(\mathbb{C}^{n\times n})^{l+1}$.

In Sections 34.1 to 34.3, we give an informal introduction to quivers from a linear algebraist's point of view. Exact definitions, results, and their proofs can be found in surveys [DW05, Sav06] and monographs [ASS06, ARS95, DR76, GR92, HGK07, Rin84]. After Gabriel's article [Gab72], in which the notions of a quiver and its representations were introduced, it became clear that a whole range of problems about systems of linear mappings can be formulated and studied in a uniform way. Quivers arise naturally in many areas of mathematics (representation theory, algebraic and differential geometry, number theory, Kac-Moody algebras, quantum groups, geometric invariant theory) and physics (string theory, supersymmetry, black holes, particle physics). Each finite dimensional algebra can be given by a quiver with relations, and representations of the algebra can be identified with representations of this quiver; that is, with finite systems of linear mappings satisfying some relations. Thus, the theory of representations of finite dimensional algebras can be considered as a branch of linear algebra.

In Sections 34.4 and 34.5, we present definitions that extend the notion of quiver representations to representations of mixed graphs, which permits one to study systems of linear mappings and bilinear or sesquilinear forms. The problem of classifying such systems reduces to the problem of classifying systems of linear mappings.

34.1 Systems of Linear Mappings as Representations of Quivers

Definitions:

A **quiver** Q is a directed graph in which multiple arcs are allowed (see Section 40.1). Its arcs are called *arrows*. We suppose that the vertices of Q are $1, \dots, t$ and denote by $\alpha : i \longrightarrow j$ an arrow α from a vertex i to a vertex j.

A **representation** $\mathcal{A}$ of Q over a field F is given by assigning to each vertex i a finite dimensional vector space A_i over F and to each arrow $\alpha : i \longrightarrow j$ a linear mapping $A_\alpha : A_i \to A_j$.

The **dimension** of $\mathcal{A}$ is the vector $\mathbf{z} = (\dim A_1, \dots, \dim A_t)$.

A **morphism** $\varphi : \mathcal{A} \to \mathcal{B}$ between representations $\mathcal{A}$ and $\mathcal{B}$ of Q is a family of linear mappings $\varphi_1 : A_1 \to B_1, \dots, \varphi_t : A_t \to B_t$ such that the diagram

$$\begin{tikzcd}
A_i \arrow[r, "A_\alpha"] \arrow[d, "\varphi_i"'] & A_j \arrow[d, "\varphi_j"] \\
B_i \arrow[r, "B_\alpha"] & B_j
\end{tikzcd}$$

is commutative (i.e., $\varphi_j A_\alpha = B_\alpha \varphi_i$) for each arrow $\alpha : i \longrightarrow j$.

An **isomorphism** $\varphi : \mathcal{A} \xrightarrow{\sim} \mathcal{B}$ is a morphism $\varphi : \mathcal{A} \to \mathcal{B}$ in which all φ_i are bijections.

The **direct sum** of representations $\mathcal{A}$ and $\mathcal{B}$ of Q is the representation $\mathcal{A} \oplus \mathcal{B}$ of Q defined by $(A \oplus B)_i := A_i \oplus B_i$ for all vertices i and $(A \oplus B)_\alpha := A_\alpha \oplus B_\alpha$ for all arrows α. (The direct sum of linear mappings $A : U \to V$ and $A' : U' \to V'$ is the linear mapping $A \oplus A' : U \oplus U' \to V \oplus V'$ defined by $A \oplus A' : u + u' \mapsto Au + A'u'$ for all $u \in U$ and $u' \in U'$.)

A representation of nonzero dimension is **indecomposable** if it is not isomorphic to a direct sum of representations of smaller dimensions.

Facts:

1. [HGK07, Corollary 2.4.2] *The Krull–Schmidt theorem:* Each representation of a quiver is isomorphic to a direct sum of indecomposable representations. This direct sum is uniquely determined, up to permutation and isomorphisms of direct summands: if $\mathcal{A}_1 \oplus \cdots \oplus \mathcal{A}_r \simeq \mathcal{B}_1 \oplus \cdots \oplus \mathcal{B}_s$, in which all $\mathcal{A}_i$ and $\mathcal{B}_j$ are indecomposable representations, then $r = s$ and all $\mathcal{A}_i \simeq \mathcal{B}_i$ after a suitable renumbering of $\mathcal{A}_1, \dots, \mathcal{A}_r$.

Examples:

1. Each representation
$$\begin{tikzcd}
& A_2 \arrow[dr, "A_\varepsilon"] & \\
A_1 \arrow[loop left, "A_\alpha"] \arrow[ur, "A_\beta"] \arrow[rr, shift left, "A_\gamma"] \arrow[rr, shift right, "A_\delta"'] & & A_3 \arrow[loop right, "A_\zeta"]
\end{tikzcd}$$
of the quiver
$$\begin{tikzcd}
& 2 \arrow[dr, "\varepsilon"] & \\
1 \arrow[loop left, "\alpha"] \arrow[ur, "\beta"] \arrow[rr, shift left, "\gamma"] \arrow[rr, shift right, "\delta"'] & & 3 \arrow[loop right, "\zeta"]
\end{tikzcd}$$
over a field F is a system of vector spaces A_1, A_2, A_3 over F and linear mappings $A_\alpha : A_1 \to A_1$, $A_\beta : A_1 \to A_2, \dots$
2. Consider the problems of classifying representations of the quivers
$$\begin{tikzcd}
1 \arrow[r] & 2, & 1 \arrow[loop right] & , & 1 \arrow[r, shift left] \arrow[r, shift right] & 2, & 1 \arrow[r, shift left] & 2, \arrow[l, shift left] & 1 \arrow[loop left] \arrow[loop right]
\end{tikzcd}$$
   (a) Each matrix $A \in F^{m \times n}$ defines the representation $F^n \xrightarrow{A} F^m$ of the quiver $1 \longrightarrow 2$ by assigning to its arrow the linear mapping $x \mapsto Ax$ with $x \in F^n$. Thus, the problem of classifying representations of the quiver $1 \longrightarrow 2$ is the canonical form problem for matrices under equivalence transformations $A \mapsto R^{-1}AS$ with nonsingular R and S. Its canonical matrices are $I \oplus 0$, and so each representation is isomorphic to a direct sum, uniquely determined up to permutations of summands, of representations of the form
$$F \xrightarrow{I_1} F, \qquad 0 \xrightarrow{0_{10}} F, \qquad F \xrightarrow{0_{01}} 0 \tag{34.1}$$
   ($F^0 = 0$ is the zero-dimensional vector space; it is agreed that there exist exactly one matrix 0_{n0} of size $n \times 0$ and exactly one matrix 0_{0n} of size $0 \times n$ for every nonnegative integer n; they are the matrices of linear mappings $0 \to F^n$ and $F^n \to 0$).

(b) The problem of classifying representations of the quiver $1 \circlearrowleft$ is the canonical form problem for a square matrix A over a field F under similarity transformations $S^{-1}AS$. Its canonical matrix is a direct sum of companion matrices

$$C_n(q) = \begin{bmatrix} 0 & & 0 & -c_n \\ 1 & \ddots & & \vdots \\ & \ddots & 0 & -c_2 \\ 0 & & 1 & -c_1 \end{bmatrix} \tag{34.2}$$

whose characteristic polynomials $q(x) = x^n + c_1x^{n-1} + \cdots + c_n$ are powers of irreducible polynomials. This canonical matrix is called the elementary divisors rational canonical form of A (see Section 6.5) or the Frobenius canonical form of A. Thus, each representation of $1 \circlearrowleft$ is isomorphic to a direct sum, uniquely determined up to permutation of summands, of representations of the form $F^n \circlearrowleft_{C_n(q)}$. If F is an algebraically closed field, then a Jordan block $J_n(\lambda)$ can be taken instead of $C_n(q)$.

(c) The problem of classifying representations of the quiver $1 \rightrightarrows 2$ is the canonical form problem for pairs (A, B) of matrices of the same size under equivalence transformations $(R^{-1}AS, R^{-1}AS)$ with nonsingular R and S. By Kronecker's theorem on pencils of matrices (Section 78.3), each representation of $1 \rightrightarrows 2$ is isomorphic to a direct sum, uniquely determined up to permutations of summands, of representations of the form

$$F^n \underset{C_n(q)}{\overset{I_n}{\rightrightarrows}} F^n\ , \quad F^n \underset{I_n}{\overset{J_n(0)}{\rightrightarrows}} F^n\ , \quad F^n \underset{R_n}{\overset{L_n}{\rightrightarrows}} F^{n-1}\ , \quad F^{n-1} \underset{R_n^T}{\overset{L_n^T}{\rightrightarrows}} F^n\ , \tag{34.3}$$

in which $n = 1, 2, \ldots,$

$$L_n := \begin{bmatrix} 1 & 0 & & 0 \\ & \ddots & \ddots & \\ 0 & & 1 & 0 \end{bmatrix}, \quad R_n := \begin{bmatrix} 0 & 1 & & 0 \\ & \ddots & \ddots & \\ 0 & & 0 & 1 \end{bmatrix} \quad ((n-1)\text{-by-}n,\ L_1 = R_1 =: 0_{01}), \tag{34.4}$$

and $C_n(q)$ is a block (34.2), which can be replaced by a Jordan block if F is algebraically closed.

(d) [DP65, HM95] The problem of classifying representations of the quiver $1 \rightleftarrows 2$ is the canonical form problem for pairs (A, B) of $p \times q$ and $q \times p$ matrices under contragredient equivalence transformations $(R^{-1}AS, S^{-1}AR)$ with nonsingular R and S. Each representation of $1 \rightleftarrows 2$ is isomorphic to a direct sum, determined uniquely up to permutation of summands, of representations of the form

$$F^n \underset{C_n(q)}{\overset{I_n}{\rightleftarrows}} F^n\ , \quad F^n \underset{I_n}{\overset{J_n(0)}{\rightleftarrows}} F^n\ , \quad F^n \underset{R_n^T}{\overset{L_n}{\rightleftarrows}} F^{n-1}\ , \quad F^{n-1} \underset{R_n}{\overset{L_n^T}{\rightleftarrows}} F^n\ ,$$

in which $n = 1, 2, \ldots,$ the matrices L_n and R_n are defined in Eq. (34.4), and $C_n(q)$ is a block (34.2), which can be replaced by a Jordan block if F is algebraically closed.

34.2 Tame and Wild Quivers

The problem of classifying pairs of $n \times n$ matrices under similarity transformations

$$(A, B) \mapsto (S^{-1}AS, S^{-1}BS), \qquad S \text{ is nonsingular}$$

(i.e., representations of the quiver $\circlearrowleft 1 \circlearrowright$) plays a special role in the theory of quiver representations: it contains the problem of classifying representations of each quiver.

Definitions:

A quiver is of **finite type** if it has only finitely many nonisomorphic indecomposable representations.

A quiver is of **wild type** if the problem of classifying its representations contains the problem of classifying matrix pairs up to similarity; otherwise, the quiver is of **tame type** (see formal definitions in [GR92, Sect. 14.10]).

The **Tits form** $q_Q : \mathbb{Z}^t \to \mathbb{Z}$ of a quiver Q with vertices $1, \ldots, t$ is the quadratic form

$$q_Q(x_1, \ldots, x_t) := x_1^2 + \cdots + x_t^2 - \sum_{i \longrightarrow j} x_i x_j \tag{34.5}$$

in which the sum is taken over all arrows of the quiver.

Facts:

1. [GP69] The problem of classifying pairs of commuting nilpotent matrices up to similarity contains the problem of classifying arbitrary matrix pairs up to similarity (see Example 1).
2. [GP69, BS03] The problem of classifying matrix pairs up to similarity contains the problem of classifying representations of any quiver (see Example 2).
3. [Gab72] *Gabriel's theorem:* Let Q be a connected quiver with t vertices.

   (a) Q is of finite type if and only if the Tits form q_Q (considered as a form over $\mathbb{R}$; see Section 13.2) is positive definite, if and only if Q can be obtained by directing edges in one of the Dynkin diagrams

   
   (34.6)

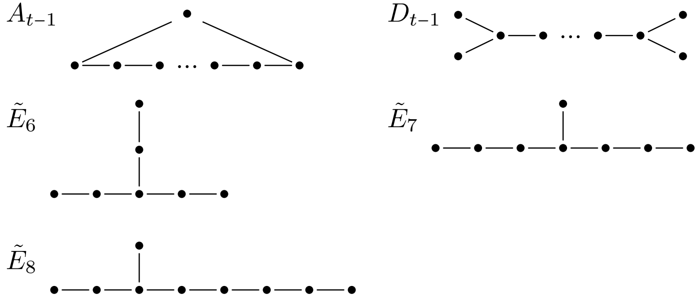
   (the index is the number of vertices).

   (b) Let Q be of finite type and let $\mathbf{z} = (z_1, \ldots, z_t)$ be an integer vector with nonnegative components. There exists an indecomposable representation of dimension $\mathbf{z}$ if and only if $q_Q(\mathbf{z}) = 1$; this representation is determined by $\mathbf{z}$ uniquely up to isomorphism. (Representations of quivers of finite type were classified by Gabriel [Gab72]; see also [HGK07, Theorem 2.6.1].)

4. [DF73, Naz73] *The Donovan–Freislich–Nazarova theorem:* Let Q be a connected quiver with t vertices.

   (a) Q is of tame type if and only if the Tits form q_Q is positive semidefinite, if and only if Q can be obtained by directing edges in one of the Dynkin diagrams

(34.6) or the extended Dynkin diagrams



(the index plus one is the number of vertices).

(b) Let Q be of tame type and let $\mathbf{z} = (z_1, \dots, z_t)$ be an integer vector with nonnegative components. There exists an indecomposable representation of dimension $\mathbf{z}$ if and only if $q_Q(\mathbf{z}) = 0$ or 1. (Representations of quivers of tame type were classified independently in [DF73] and [Naz73].)

5. [Kac80] *Kac's theorem:* Let F be an algebraically closed field. The set of dimensions of indecomposable representations of a quiver Q with t vertices over F coincides with the positive root system $\Delta_+(Q)$ defined in [Kac80]. The following holds for $\mathbf{z} \in \Delta_+(Q)$:
   (a) $q_Q(\mathbf{z}) \le 1$.
   (b) If $q_Q(\mathbf{z}) = 1$, then all representations of dimension $\mathbf{z}$ are isomorphic.
   (c) If $q_Q(\mathbf{z}) \le 0$, then there are infinitely many nonisomorphic representations of dimension $\mathbf{z}$ and the number of parameters of the set of indecomposable representations of dimension $\mathbf{z}$ is

$$1 - q_Q(\mathbf{z}) = \sum_{i \longrightarrow j} z_i z_j - (z_1^2 + \cdots + z_t^2 - 1) \quad \text{(see Example 3).}$$

6. [Bel83, Bel00] *Belitskii's algorithm:* Let F be an algebraically closed field. Belitskii constructed an algorithm that transforms each pair (A, B) of $n \times n$ matrices over F to a pair $(A_{\text{can}}, B_{\text{can}})$ that is similar to (A, B) and is such that if (A, B) is similar to (C, D), then $(A_{\text{can}}, B_{\text{can}}) = (C_{\text{can}}, D_{\text{can}})$. The pair $(A_{\text{can}}, B_{\text{can}})$ is called *Belitskii's canonical form* of (A, B) under similarity. We can define *Belitskii's canonical pairs* as those matrix pairs that are not changed by Belitskii's algorithm, but we cannot expect to obtain an explicit description of them. Shmuel Friedland's alternative approach to the problem of classifying matrix pairs up to similarity is presented in Chapter 33.
7. [Ser00] *The tame and wild theorem:* Belitskii's algorithm was extended to a wide class of matrix problems over an algebraically closed field F that includes the problems of classifying representations of quivers and representations of finite dimensional algebras. For each matrix problem from this class, denote by Bel_{mn} the set of $m \times n$ indecomposable Belitskii canonical matrices and consider Bel_{mn} as a subset in the affine space of $m \times n$ matrices $F^{m \times n}$. Then
   (a) either Bel_{mn} consists of a finite number of points and straight lines for every $m \times n$ (then the matrix problem is of tame type), or
   (b) Bel_{mn} contains a 2-dimensional plane for a certain $m \times n$ (then the matrix problem is of wild type).

   This statement is a geometric form of Drozd's tame and wild theorem [Dro80].

Examples:

1. Two pairs (A,B) and (A',B') of $n \times n$ matrices are similar if and only if the pairs

$$\left(\begin{bmatrix} \begin{array}{ccc|c} 0 & I_n & 0 & 0 \\ 0 & 0 & I_n & 0 \\ 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \end{array} \end{bmatrix}, \begin{bmatrix} \begin{array}{ccc|c} 0 & A & 0 & I_n \\ 0 & 0 & A & 0 \\ 0 & 0 & 0 & 0 \\ \hline 0 & 0 & B & 0 \end{array} \end{bmatrix}\right) \quad \text{and} \quad \left(\begin{bmatrix} \begin{array}{ccc|c} 0 & I_n & 0 & 0 \\ 0 & 0 & I_n & 0 \\ 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \end{array} \end{bmatrix}, \begin{bmatrix} \begin{array}{ccc|c} 0 & A' & 0 & I_n \\ 0 & 0 & A' & 0 \\ 0 & 0 & 0 & 0 \\ \hline 0 & 0 & B' & 0 \end{array} \end{bmatrix}\right)$$

   of commuting nilpotent $4n \times 4n$ matrices are similar. Thus, a solution of the problem of classifying pairs of commuting nilpotent matrices up to similarity would imply a solution of the problem of classifying pairs of arbitrary matrices up to similarity.
2. Two representations

$$\begin{tikzcd} & F^q \arrow[dr, "E"] & \\ F^p \arrow[loop left, "A"] \arrow[ur, "B"] \arrow[rr, shift left, "C"] \arrow[rr, shift right, "D"'] & & F^r \arrow[loop right, "F"] \end{tikzcd} \quad \text{and} \quad \begin{tikzcd} & F^{q'} \arrow[dr, "E'"] & \\ F^{p'} \arrow[loop left, "A'"] \arrow[ur, "B'"] \arrow[rr, shift left, "C'"] \arrow[rr, shift right, "D'"'] & & F^{r'} \arrow[loop right, "F'"] \end{tikzcd}$$

   are isomorphic over a field with at least 4 distinct elements $\alpha, \beta, \gamma, \delta$ if and only if the pairs

$$\left(\begin{bmatrix} \alpha I_p & 0 & 0 & 0 \\ 0 & \beta I_q & 0 & 0 \\ 0 & 0 & \gamma I_r & 0 \\ 0 & 0 & 0 & \delta I_r \end{bmatrix}, \begin{bmatrix} A & 0 & 0 & 0 \\ B & 0 & 0 & 0 \\ C & 0 & 0 & 0 \\ D & E & I_r & F \end{bmatrix}\right) \quad \text{and} \quad \left(\begin{bmatrix} \alpha I_{p'} & 0 & 0 & 0 \\ 0 & \beta I_{q'} & 0 & 0 \\ 0 & 0 & \gamma I_{r'} & 0 \\ 0 & 0 & 0 & \delta I_{r'} \end{bmatrix}, \begin{bmatrix} A' & 0 & 0 & 0 \\ B' & 0 & 0 & 0 \\ C' & 0 & 0 & 0 \\ D' & E' & I_{r'} & F' \end{bmatrix}\right)$$

   are similar. This example can be extended to representations of any quiver over any field as in [DHK12, Sect. 5].
3. The statement about the number of parameters in Fact 5(c) is intuitively clear: Let $\mathcal{A}$ be a representation of dimension $\mathbf{z}$. In some bases of $A_1, \dots, A_t$, let M_α be the matrix of A_α for an arrow $\alpha : i \longrightarrow j$. Let $S_1, \dots, S_t$ be the change of basis matrices. Then the $\sum_{i \to j} z_i z_j$ entries of M_α's are reduced by $z_1^2 + \cdots + z_t^2$ entries of S_i's. But really only $z_1^2 + \cdots + z_t^2 - 1$ independent parameters are used since multiplying all S_i by the same nonzero scalar does not change the transformation $M_\alpha \mapsto S_j^{-1} M_\alpha S_i$ for all arrows $\alpha : i \longrightarrow j$.

34.3 Quivers of Finite Dimensional Algebras

All representations of a finite dimensional algebra can be identified with all representations of some quiver with relations.

Definitions:

A **relation** in a quiver Q over a field F is a formal expression of the form

$$\sum_{i=1}^{m} c_i \alpha_{ip_i} \cdots \alpha_{i2} \alpha_{i1} = 0, \qquad 0 \neq c_i \in F, \tag{34.7}$$

in which all

$$u \xrightarrow{\alpha_{i1}} u_{i2} \xrightarrow{\alpha_{i2}} \cdots \xrightarrow{\alpha_{i,p_i-1}} u_{ip_i} \xrightarrow{\alpha_{ip_i}} v, \qquad i = 1, \dots, m,$$

are **directed paths** in Q (i.e., directed walks in the terminology of Chapter 40) with the same start vertex u and the same end vertex v; it is possible that $u = v$.

A representation $\mathcal{A}$ of Q **satisfies the relation** (34.7) if

$$\sum_{i=1}^{m} c_i A_{\alpha_{ip_i}} \cdots A_{\alpha_{i2}} A_{\alpha_{i1}} = 0. \tag{34.8}$$

If $u = v$, then Eq. (34.7) may have a summand $c_i \varepsilon_u$, in which ε_u is the path without arrows. This "lazy" path ε_u (to stand in place) is replaced in Eq. (34.8) by the identity operator on A_u.

By a **quiver with relations** (Q, L) we mean a quiver Q with a finite set L of relations. Its **set of representations** consists of all representations of Q that satisfy all relations from L.

The **path algebra** FQ of a quiver Q is a finite dimensional algebra over a field F whose elements are formal linear combinations $\sum_{i=1}^{m} c_i \alpha_{ip_i} \cdots \alpha_{i2} \alpha_{i1}$ in which $c_i \in F$ and $\alpha_{ip_i} \cdots \alpha_{i2} \alpha_{i1}$ are directed paths (they may be lazy paths and may have distinct start vertices and distinct end vertices). Their multiplication is determined by the distributive law and the rule:

$$(\beta_q \cdots \beta_1)(\alpha_p \cdots \alpha_1) = \begin{cases} \beta_q \cdots \beta_1 \alpha_p \cdots \alpha_1 & \text{if the end vertex of } \alpha_p \text{ is the start vertex of } \beta_1, \\ 0 & \text{otherwise.} \end{cases}$$

The multiplicative identity of the algebra FQ is the sum $\varepsilon_1 + \cdots + \varepsilon_t$ of all lazy paths taken over all vertices. If (Q, L) is a quiver with relations, then its **path algebra** $F(Q, L)$ is determined modulo these relations; that is, $F(Q, L) := FQ/\mathcal{L}$ in which $\mathcal{L}$ is the two-sided ideal of FQ generated by the left-hand sides of relations from L.

A **representation** of a finite dimensional algebra Λ over F is a homomorphism $\varphi : \Lambda \to \operatorname{End} V$ to the algebra $\operatorname{End} V$ of linear operators on a vector space V over F.

An algebra over an algebraically closed field F is called a **basic algebra** if for some positive integer m it is isomorphic to an algebra Λ of upper triangular $m \times m$ matrices over F that satisfies the condition:

$$\begin{bmatrix} a_{11} & \ldots & a_{1m} \\ & \ddots & \vdots \\ 0 & & a_{mm} \end{bmatrix} \in \Lambda \qquad \Longrightarrow \qquad \begin{bmatrix} a_{11} & & 0 \\ & \ddots & \\ 0 & & a_{mm} \end{bmatrix} \in \Lambda.$$

Facts:

1. Each finite dimensional algebra Λ over a field F is isomorphic to the path algebra $F(Q, L)$ of a quiver with relations (Q, L), which is constructed in [ASS06, Chap. II]. We give a simplified construction of (Q, L) in the following algorithm.

Algorithm 1: From an algebra $\boldsymbol{\Lambda}$ to a quiver $\boldsymbol{(Q, L)}$.

1. Decompose the unit of Λ into a sum of orthogonal idempotents:
$$1 = e_1 + \cdots + e_t, \qquad e_i e_j = 0 \text{ if } i \neq j, \quad e_i^2 = e_i \neq 0. \tag{34.9}$$
2. Choose a set $a_1, \ldots, a_n$ of elements of Λ such that $e_1, \ldots, e_t, a_1, \ldots, a_n$ generate Λ and each a_i is equal to $e_{q(i)} a_i e_{p(i)}$ for some $p(i)$ and $q(i)$ (such a set exists since if $b_1, b_2, \ldots$ generate Λ, then all $e_i b_j e_k$ also generate Λ).
3. Denote by Q the quiver with vertices $1, \ldots, t$ and n arrows $\alpha_i : p(i) \longrightarrow q(i)$.
4. Denote by $\pi : FQ \to \Lambda$ the epimorphism of algebras such that $\pi(\varepsilon_1) = e_1, \ldots, \pi(\varepsilon_t) = e_t$, $\pi(\alpha_1) = a_1, \ldots, \pi(\alpha_n) = a_n$.
5. Construct a set L of relations in Q by choosing a finite subset of $\cup \varepsilon_j \operatorname{Ker}(\pi) \varepsilon_i$ that generates $\operatorname{Ker}(\pi)$, expressing its elements through $\varepsilon_1, \ldots, \varepsilon_t, \alpha_1, \ldots, \alpha_n$, and equating them to zero.

Then $F(Q, L) \simeq FQ/\operatorname{Ker}(\pi) \simeq \Lambda$.

2. Let Λ be an algebra and (Q, L) be its quiver constructed in Algorithm 1. In the following algorithm, a canonical correspondence $\varphi \longleftrightarrow \mathcal{R}$ between representations of Λ and representations of (Q, L) is constructed such that φ and φ' are isomorphic if and only if the corresponding representations $\mathcal{R}$ and $\mathcal{R}'$ are isomorphic.

Algorithm 2: From a representation $\varphi : \Lambda \to \operatorname{End} V$ of Λ to a representation $\mathcal{R}$ of (Q, L).

1 Since Eq. (34.9) holds for $\tau_i := \varphi(e_i) : V \to V$ instead of e_i, we have $V = \tau_1 V \oplus \cdots \oplus \tau_t V$. Put $R_i := \tau_i V$ for every vertex $i = 1, \dots, t$.

2 For each a_i from Step 2 of Algorithm 1, define $\rho_i := \varphi(a_i) : V \to V$. Since $\rho_i = \tau_{q(i)} \rho_i \tau_{p(i)}$, we have $\rho_i(\tau_{p(i)} V) \subseteq \tau_{q(i)} V$ and $\rho_i(\tau_k V) = 0$ if $k \neq p(i)$, and so each ρ_i is fully determined by its restriction $\rho_i|_{\tau_{p(i)} V} : \tau_{p(i)} V \to \tau_{q(i)} V$. Put $R_{\alpha_i} := \rho_i|_{\tau_{p(i)} V}$ for every arrow $\alpha_i : p(i) \longrightarrow q(i)$.

3. [ASS06, Corollary I.6.10] If the field F is algebraically closed, then it suffices to study representations of basic algebras since for each finite dimensional algebra over F there exists a basic algebra over F such that the categories of representations of these algebras are equivalent. One usually applies Algorithms 1 and 2 to a basic algebra Λ over F, chooses $a_1, \dots, a_n$ among its nilpotent elements, and takes the numbers t and n to be maximal and minimal, respectively.

Examples:

1. The path algebra $F(Q, L)$ of the quiver $\begin{tikzcd} & 2 \arrow[dr, "\beta"] & \\ 1 \arrow[ur, "\alpha"] \arrow[dr, "\gamma"'] & & 4 \\ & 3 \arrow[ur, "\delta"'] & \end{tikzcd}$ with relation $\beta\alpha = \delta\gamma$ has the basis $\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \alpha, \beta, \gamma, \delta, \beta\alpha$ over F. The product of $\varepsilon_3 - \delta + \beta\alpha$ and $\varepsilon_1 + 2\gamma$ in $F(Q, L)$ is
$$\varepsilon_3\varepsilon_1 - \delta\varepsilon_1 + \beta\alpha\varepsilon_1 + 2\varepsilon_3\gamma - 2\delta\gamma + 2\beta\alpha\gamma = \beta\alpha + 2\gamma - 2\delta\gamma = -\beta\alpha + 2\gamma.$$
Each representation $\mathcal{A}$ of (Q, L) defines a representation of $F(Q, L)$ by operators on the space $A_1 \oplus A_2 \oplus A_3 \oplus A_4$.
2. The problem of classifying representations of the quiver with relations
$$\begin{tikzcd} 1 \arrow[loop left, "\alpha"] \arrow[loop right, "\beta"] \end{tikzcd} \qquad\qquad \alpha\beta = \beta\alpha = 0$$
is the problem of classifying pairs of mutually annihilating operators $AB = BA = 0$, which was solved in [GP68] (see also [BGS09]). Its path algebra is an infinite dimensional algebra whose elements are finite linear combinations of $\varepsilon_1, \alpha, \alpha^2, \alpha^3, \dots, \beta, \beta^2, \beta^3, \dots$ over F.
3. Let us apply Algorithm 1 to the basic algebra
$$\Lambda := \left\{ \begin{bmatrix} u & x & z \\ 0 & u & y \\ 0 & 0 & v \end{bmatrix} : u, v, x, y, z \in \mathbb{C} \right\}.$$
Decompose its unit into a sum of orthogonal idempotents: $I_3 = e_1 + e_2$, in which $e_1 := \operatorname{diag}(1, 1, 0)$ and $e_2 := \operatorname{diag}(0, 0, 1)$. Write
$$a_1 := \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = e_1 a_1 e_1, \qquad a_2 := \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} = e_1 a_2 e_2\,.$$
The elements e_1, e_2, a_1, a_2 generate Λ. We obtain the quiver with relations

$$\begin{tikzcd} 1 \arrow[loop left, "\alpha_1"] & 2 \arrow[l, "\alpha_2"'] \end{tikzcd} \qquad \alpha_1^2 = 0 \tag{34.10}$$

whose path algebra is isomorphic to Λ. Each representation of Λ is obtained from a representation of the quiver (34.10) and vice versa.

34.4 Systems of Linear Mappings and Forms as Representations of Mixed Graphs

By analogy with quiver representations, systems of linear mappings and forms can be considered as representations of mixed graphs, in which forms are assigned to undirected edges.

Definitions:

Let F be a field with a fixed involution $a \mapsto \overline{a}$ (i.e., a bijection $F \to F$ satisfying $\overline{a+b} = \overline{a} + \overline{b}$, $\overline{ab} = \overline{a}\,\overline{b}$, and $\overline{\overline{a}} = a$), which can be the identity.

A **mixed graph** G is a graph in which loops and multiple edges are allowed and that may contain both directed and undirected edges; we suppose that the vertices are $1, \dots, t$.

A **representation** $\mathcal{A}$ of G over F is given by assigning to each vertex i a finite dimensional vector space A_i over F, to each directed edge $\alpha : i \longrightarrow j$ a linear mapping $A_\alpha : A_i \to A_j$, and to each undirected edge $\lambda : i \text{---} j$ $(i \leq j)$ a sesquilinear form $A_\lambda : A_j \times A_i \to F$; this form is bilinear if the fixed involution on F is the identity. We suppose that A_λ is linear on A_i and semilinear on A_j.

An **isomorphism** $\varphi : \mathcal{A} \xrightarrow{\sim} \mathcal{B}$ between representations $\mathcal{A}$ and $\mathcal{B}$ of G is a family of linear bijections $\varphi_1 : A_1 \to B_1, \dots, \varphi_t : A_t \to B_t$ such that $\varphi_j A_\alpha = B_\alpha \varphi_i$ for each directed edge $\alpha : i \longrightarrow j$ and $A_\lambda(y, x) = B_\lambda(\varphi_j y, \varphi_i x)$ for each undirected edge $\lambda : i \text{---} j$.

The notions of the **dimension** of a representation, **direct sum**, and **finite, tame, and wild types** are defined for mixed graphs in the same way as for quivers. The **Tits form** is defined as in Eq. (34.5), but the sum is also taken over all undirected edges $i \text{---} j$ $(i \leq j)$.

Facts:

1. [Ser88] The Krull–Schmidt, Gabriel, and Donovan–Freislich–Nazarova theorems (see Facts 34.1.1, 34.2.3, and 34.2.4) remain true if we replace the word "quiver" with "mixed graph."
2. [Ser83, Ser07] *A generalization of Kac's theorem* (see Fact 34.2.5): Let F be an algebraically closed field of characteristic not 2. The set of dimensions of indecomposable representations of a mixed graph G over F coincides with the positive root system $\Delta_+(G)$ (its definition in [Kac80] does not depend on the orientation of edges).

Examples:

1. Each representation

$$\begin{tikzcd} & A_1 & \\ A_2 \arrow[ur, dash, "A_\lambda"] \arrow[loop left, dash, "A_\mu"] \arrow[rr, shift left, "A_\beta"] \arrow[rr, shift right, dash, "A_\nu"'] & & A_3 \arrow[ul, "A_\alpha"'] \arrow[loop right, "A_\gamma"] \end{tikzcd}$$

of

$$\begin{tikzcd} & 1 & \\ 2 \arrow[ur, dash, "\lambda"] \arrow[loop left, dash, "\mu"] \arrow[rr, shift left, "\beta"] \arrow[rr, shift right, dash, "\nu"'] & & 3 \arrow[ul, "\alpha"'] \arrow[loop right, "\gamma"] \end{tikzcd}$$

is a system of vector spaces A_1, A_2, A_3 over F, linear mappings A_α, A_β, A_γ, and sesquilinear forms $A_\lambda : A_2 \times A_1 \to F$, $A_\mu : A_2 \times A_2 \to F$, $A_\nu : A_3 \times A_2 \to F$ (these forms are bilinear if the fixed involution on F is the identity).

34.5 Generalization of the Law of Inertia to Representations of Mixed Graphs

The problem of classifying systems of forms and linear mappings over $\mathbb{C}$ and $\mathbb{R}$ is reduced to the problem of classifying systems of linear mappings.

Definitions:

Let V be a finite dimensional vector space V over a field F with a fixed involution (which can be the identity).

By the ***dual space** of V, we mean the space $V^\star$ of all mappings $\varphi : V \to F$ that are **semilinear**, i.e., $\varphi(au + bv) = \bar{a}\varphi(u) + \bar{b}\varphi(v)$ for all $u, v \in V$ and $a, b \in F$.

For each linear mapping $A : U \to V$, we define the ***adjoint mapping** $A^\star : V^\star \to U^\star$ by putting $A^\star\varphi := \varphi A$ for all $\varphi \in V^\star$.

For each mixed graph G, we denote by $\underline{G}$ the quiver that is obtained from G by replacing

- each vertex i of G by the vertices i and $i^\star$,
- each arrow $\alpha : i \longrightarrow j$ by the arrows $\alpha : i \longrightarrow j$ and $\alpha^\star : j^\star \longrightarrow i^\star$,
- each undirected edge $\lambda : i \,\text{---}\, j$ $(i \le j)$ by the arrows $\lambda : i \longrightarrow j^\star$ and $\lambda^\star : j \longrightarrow i^\star$.

We consider $\underline{G}$ as a **quiver with involution** on the set of vertices and on the set of arrows.

For each representation $\mathcal{A}$ over F of a mixed graph G, we denote by $\underline{\mathcal{A}}$ the representation of $\underline{G}$ that is obtained from $\mathcal{A}$ by replacing (see Example 3)

- each vector space A_i by the mutually *dual spaces A_i and $A_i^\star$,
- each linear mapping $A_\alpha : A_i \to A_j$ by the mutually *adjoint mappings $A_\alpha : A_i \to A_j$ and $A_\alpha^\star : A_j^\star \to A_i^\star$,
- each sesquilinear form $A_\lambda : A_j \times A_i \to F$ by the mutually *adjoint mappings $A_\lambda : u \in A_i \mapsto A_\lambda(?, u) \in A_j^\star$ and $A_\lambda^\star : v \in A_j \mapsto \overline{A_\lambda(v, ?)} \in A_i^\star$.

For each representation $\mathcal{M}$ of $\underline{G}$, we define the **adjoint representation** $\mathcal{M}^\circ$ of $\underline{G}$ that is formed by the vector spaces $M_v^\circ := M_{v^\star}^\star$ for all vertices v of $\underline{G}$ and the linear mappings $M_\tau^\circ := M_{\tau^\star}^\star$ for all arrows τ of $\underline{G}$ (see Example 4).

A representation $\mathcal{M}$ of $\underline{G}$ is **selfadjoint** if $\mathcal{M}^\circ = \mathcal{M}$.

A **mixed graph with relations** (G, L) is a mixed graph G with a finite set L of relations in $\underline{G}$. By **representations of** (G, L) we mean those representations $\mathcal{A}$ of G for which $\underline{\mathcal{A}}$ satisfies L.

For each relation $\sum_{i=1}^{m} c_i \tau_{ip_i} \cdots \tau_{i2}\tau_{i1} = 0$ in $\underline{G}$ (see Eq. (34.7)), we define the **adjoint relation** $\sum_{i=1}^{m} \bar{c}_i \tau_{i1}^\star \tau_{i2}^\star \cdots \tau_{ip_i}^\star = 0$ in $\underline{G}$. For each set L of relations in $\underline{G}$, we denote by $L^\star$ the set of relations that are adjoint to the relations from L.

For each representation $\mathcal{A}$ of G, we denote by $\mathcal{A}^-$ the representation of G that is obtained from $\mathcal{A}$ by replacing all its forms A_λ by $-A_\lambda$.

Facts:

1. In the following algorithm, the problem of classifying representations of a mixed graph with relations (G, L) over $\mathbb{C}$ and $\mathbb{R}$ is reduced to the problem of classifying representations of the quiver with relations $(\underline{G}, L \cup L^\star)$. The algorithm is a special case of the method that was developed in [Roi79, Ser88] and used in [HS08, Ser07, Ser08] for reducing the problem of classifying representations of a mixed graph (G, L) over a field or skew field F of characteristic not 2 to the problem of classifying representations of the quiver $(\underline{G}, L \cup L^\star)$ over F and the problem of classifying Hermitian and symmetric forms over fields and skew fields that are finite extensions of the center of F.

Algorithm 3: A method for classifying representations of a mixed graph with relations (G, L).

1. Construct a set $\mathfrak{I} := \operatorname{ind}(\underline{G}, L \cup L^\star)$ of indecomposable representations of $(\underline{G}, L \cup L^\star)$ over $F = \mathbb{C}$ or $\mathbb{R}$ such that every indecomposable representation of $(\underline{G}, L \cup L^\star)$ is isomorphic to exactly one representation from $\mathfrak{I}$.
2. Each $\mathcal{M} \in \mathfrak{I}$ that is isomorphic to a self-adjoint representation replace by a self-adjoint representation. Denote by $\mathfrak{I}_0$ the obtained set of self-adjoint representations.
3. In each of the one- or two-element subsets $\{\mathcal{M}, \mathcal{N}\} \subset \mathfrak{I} \setminus \mathfrak{I}_0$ such that $\mathcal{M}^\circ \simeq \mathcal{N}$, select one representation and denote the set of selected representations by $\mathfrak{I}_1$.

Then every representation of (G, L) over F is isomorphic to a direct sum, uniquely determined up to permutation of summands, of representations of the types

$$\begin{array}{rl} \mathcal{A},\ \mathcal{B} & \text{if } F = \mathbb{C} \text{ with the indentity involution,} \\ \mathcal{A},\ \mathcal{B},\ \mathcal{B}^- & \text{if } F = \mathbb{C} \text{ with complex conjugation,} \\ \mathcal{A},\ \mathcal{B}, \text{ and also } \mathcal{B}^- \text{ if } \mathcal{B}^- \not\simeq \mathcal{B} & \text{if } F = \mathbb{R}, \end{array}$$

in which $\mathcal{A}$ and $\mathcal{B}$ are such that $\underline{\mathcal{A}} = \mathcal{M} \oplus \mathcal{M}^\circ$, $\mathcal{M} \in \mathfrak{I}_1$, and $\underline{\mathcal{B}} \in \mathfrak{I}_0$.

Thus, each system of linear mappings and bilinear forms over $\mathbb{C}$ or $\mathbb{R}$ and each system of linear mappings and sesquilinear forms over $\mathbb{C}$ are decomposed into direct sums of indecomposables uniquely, up to isomorphisms of summands. This is the Krull–Schmidt theorem for representations of mixed graphs; see Fact 34.4.1.

Examples:

1. The problems of classifying representations over a field F of the mixed graphs with relations
   - (a) $1 \supset \lambda$
   - (b) $\lambda \subset 1 \supset \mu$ $\quad \lambda = \varepsilon\lambda^\star,\ \mu = \delta\mu^\star$
   - (c) $\alpha \circlearrowright 1 \supset \lambda$ $\quad \lambda = \varepsilon\lambda^\star$ is nonsingular, $\alpha^\star\lambda = \lambda\alpha$
   - (d) $\alpha \circlearrowright 1 \supset \lambda$ $\quad \lambda = \varepsilon\lambda^\star = \alpha^\star\lambda\alpha$ is nonsingular

   (in which $\varepsilon, \delta \in \{-1, 1\}$) are the problems of classifying
   - (a) sesquilinear (bilinear if the involution on F is the identity) forms,
   - (b) pairs of ε-, δ-Hermitian (symmetric, or skew-symmetric) forms,
   - (c) triples (V, H, A), in which V is a vector space, H is a nonsingular ε-Hermitian (symmetric, or skew-symmetric) form on V, and A is a linear operator on V that is ^{H}*selfadjoint*, i.e., $H(Ax, y) = H(x, Ay)$ for all $x, y \in V$.
   - (d) triples (V, H, A), in which V is a vector space, H is a nonsingular ε-Hermitian (symmetric, or skew-symmetric) form on V, and A is a linear operator on V that is ^{H}*unitary*, i.e., $H(Ax, Ay) = H(x, y)$ for all $x, y \in V$.

   Canonical matrices for these problems are given in [Ser88] over any field F of characteristic not 2 up to classification of Hermitian and symmetric forms over finite extensions of F; they are based on the elementary divisors rational canonical form (see Example 34.1.2). Simpler canonical matrices over $\mathbb{C}$ and $\mathbb{R}$ that are based on the Jordan canonical form are given in [FHS08, GLR05, HS06, HS08, Ser08, Tho91].
2. The problem of classifying representations of a mixed graph (G, L) is hopeless if the quiver $(\underline{G}, L \cup L^\star)$ is of wild type. For example, the problem of classifying triples of Hermitian forms and the problem of classifying normal operators on a complex space with scalar product given by a nonsingular Hermitian form are hopeless.

3. If $\mathcal{A}:$
$$\begin{tikzcd} A_1 \arrow[d, "A_\alpha"'] \arrow[d, bend left, "A_\lambda"] \\ A_2 \arrow[loop right, "A_\mu"] \end{tikzcd}$$
is a representation of the mixed graph $G:$
$$\begin{tikzcd} 1 \arrow[d, "\alpha"'] \arrow[d, bend left, "\lambda"] \\ 2 \arrow[loop right, "\mu"] \end{tikzcd}$$
, then

$$\underline{\mathcal{A}}: \begin{tikzcd} A_1 \arrow[d, "A_\alpha"'] \arrow[dr, "A_\lambda" near start] & A_1^\star \\ A_2 \arrow[ur, "A_\lambda^\star"' near end] \arrow[r, shift left, "A_\mu"] \arrow[r, shift right, "A_\mu^\star"'] & A_2^\star \arrow[u, "A_\alpha^\star"'] \end{tikzcd} \qquad \underline{G}: \begin{tikzcd} 1 \arrow[d, "\alpha"'] \arrow[dr, "\lambda" near start] & 1^\star \\ 2 \arrow[ur, "\lambda^\star"' near end] \arrow[r, shift left, "\mu"] \arrow[r, shift right, "\mu^\star"'] & 2^\star \arrow[u, "\alpha^\star"'] \end{tikzcd} \tag{34.11}$$

4. For each representation $\mathcal{M}$ of the quiver $\underline{G}$ in (34.11), the adjoint representation $\mathcal{M}^\circ$ is constructed as follows:

$$\mathcal{M}: \begin{tikzcd} U_1 \arrow[d, "A_1"'] \arrow[dr, "B_1" near start] & U_2 \\ V_1 \arrow[ur, "B_2"' near end] \arrow[r, shift left, "C_1"] \arrow[r, shift right, "C_2"'] & V_2 \arrow[u, "A_2"'] \end{tikzcd} \qquad \mathcal{M}^\circ: \begin{tikzcd} U_2^\star \arrow[d, "A_2^\star"'] \arrow[dr, "B_2^\star" near start] & U_1^\star \\ V_2^\star \arrow[ur, "B_1^\star"' near end] \arrow[r, shift left, "C_2^\star"] \arrow[r, shift right, "C_1^\star"'] & V_1^\star \arrow[u, "A_1^\star"'] \end{tikzcd}$$

5. Algorithm 3 applied to Hermitian or symmetric forms gives the law of inertia. Indeed, these forms are representations of the mixed graph with relations $(G, L) : 1 \circlearrowleft_{\lambda=\lambda^\star}$. Its quiver $(\underline{G}, L \cup L^\star)$ is $1 \overset{\lambda}{\underset{\lambda^\star}{\rightrightarrows}} 1^\star$, $\lambda^\star = \lambda$. Using the representations in (34.1), we see that $\operatorname{ind}(\underline{G}, L \cup L^\star)$ consists of three representations:

$$\mathcal{M}: \; 0 \overset{0_{10}}{\underset{0_{10}}{\rightrightarrows}} F, \qquad \mathcal{M}^\circ: \; F \overset{0_{01}}{\underset{0_{01}}{\rightrightarrows}} 0, \qquad \mathcal{N} = \mathcal{N}^\circ: \; F \overset{[1]}{\underset{[1]}{\rightrightarrows}} F.$$

Since $\mathcal{M} \oplus \mathcal{M}^\circ = \underline{\mathcal{A}}$ in which $\mathcal{A} : F \circlearrowleft [0]$ and $\mathcal{N} = \underline{\mathcal{B}}$ in which $\mathcal{B} : F \circlearrowleft [1]$, Algorithm 3 ensures that each representation of $1 \circlearrowleft_{\lambda=\lambda^\star}$ is isomorphic to a direct sum, uniquely determined up to permutation of summands, of representations of the form:

$\mathbb{C} \circlearrowleft [0]$, $\mathbb{C} \circlearrowleft [1]$ if $F = \mathbb{C}$ with the indentity involution,
$\mathbb{C} \circlearrowleft [0]$, $\mathbb{C} \circlearrowleft [1]$, $\mathbb{C} \circlearrowleft [-1]$ if $F = \mathbb{C}$ with complex conjugation or if $F = \mathbb{R}$.

6. (See details in [HS06, Ser88].) Algorithm 3 applied to sesquilinear or bilinear forms (i.e., representations of $G : 1 \circlearrowleft \lambda$) gives their canonical matrices from Facts 7.2.6 and 7.3.2. Indeed, each representation $\mathcal{M} : U \overset{A}{\underset{B}{\rightrightarrows}} V$ of $\underline{G} : 1 \overset{\lambda}{\underset{\lambda^\star}{\rightrightarrows}} 1^\star$ defines

$$\mathcal{M}^\circ : V^\star \overset{B^\star}{\underset{A^\star}{\rightrightarrows}} U^\star \quad \text{and} \quad \mathcal{M} \oplus \mathcal{M}^\circ : \; U \oplus V^\star \overset{\left[\begin{smallmatrix} 0 & B^\star \\ A & 0 \end{smallmatrix}\right]}{\underset{\left[\begin{smallmatrix} 0 & A^\star \\ B & 0 \end{smallmatrix}\right]}{\rightrightarrows}} U^\star \oplus V$$

(in which the summands in $V \oplus U^\star$ have been interchanged to make $\mathcal{M} \oplus \mathcal{M}^\circ$ self-adjoint); $\mathcal{M} \oplus \mathcal{M}^\circ$ corresponds to $\mathcal{M}^+ : \; U \oplus V^\star \circlearrowleft \left[\begin{smallmatrix} 0 & B^\star \\ A & 0 \end{smallmatrix}\right]$ of G. Using the representations in (34.3), one can take $\operatorname{ind}(\underline{G})$ to be $\mathcal{M}_n(\lambda) : \mathbb{C}^n \overset{J_n(\lambda)}{\underset{I_n}{\rightrightarrows}} \mathbb{C}^n$ $(\lambda \neq 0)$ and pairs of mutually adjoint representations

$$\mathbb{C}^n \overset{J_n(0)}{\underset{I_n}{\rightrightarrows}} \mathbb{C}^n \;\text{ and }\; \mathbb{C}^n \overset{I_n}{\underset{J_n(0)^T}{\rightrightarrows}} \mathbb{C}^n; \quad \mathbb{C}^n \overset{L_n}{\underset{R_n}{\rightrightarrows}} \mathbb{C}^{n-1} \;\text{ and }\; \mathbb{C}^{n-1} \overset{R_n^T}{\underset{L_n^T}{\rightrightarrows}} \mathbb{C}^n. \tag{34.12}$$

(For each matrix M, $M^\star = M^*$ if the fixed involution on $\mathbb{C}$ is complex conjugation, and $M^\star = M^T$ if the involution is the identity.) $\mathcal{M}_n(\lambda)$ is isomorphic to $\mathcal{M}_n(\mu)^\circ$ if and only if $J_n(\mu)$

is similar to $J_n(\lambda)^{\star-1}$. $\mathcal{M}_n(\lambda)$ is isomorphic to a self-adjoint representation $\mathbb{C}^n \underset{A^\star}{\overset{A}{\rightrightarrows}} \mathbb{C}^n$ if and only if $A^{\star-1}A$ is similar to $J_n(\lambda)$. In the latter case, we fix one A and denote it by $\sqrt[\star]{J_n(\lambda)}$. By Fact 1, each representation of G over $\mathbb{C}$ is isomorphic to a direct sum of representations of the following forms:

(i) $\mathcal{M}_n(\lambda)^+ : \mathbb{C}^n \circlearrowleft \left[\begin{smallmatrix} 0 & I_n \\ J_n(\lambda) & 0 \end{smallmatrix}\right]$ if $\sqrt[\star]{J_n(\lambda)}$ does not exist, in which $J_n(\lambda)$ is determined up to replacement by $J_n(\mu)$ that is similar to $J_n(\lambda)^{\star-1}$;

(ii) $\mathbb{C}^n \circlearrowleft \varepsilon\sqrt[\star]{J_n(\lambda)}$, in which $\varepsilon = \pm 1$ if the involution on $\mathbb{C}$ is complex conjugation and $\varepsilon = 1$ if the involution is the identity;

(iii) $\mathbb{C}^m \circlearrowleft J_m(0)$ since $J_m(0)$ is permutationally congruent to $\left[\begin{smallmatrix} 0 & I_n \\ J_n(0) & 0 \end{smallmatrix}\right]$ if $m = 2n$ or $\left[\begin{smallmatrix} 0 & R_n^\star \\ L_n & 0 \end{smallmatrix}\right]$ if $m = 2n - 1$ (they are the matrices of representations $\mathcal{M}^+$ that are obtained from the pairs of mutually adjoint representations (34.12)).

The matrix $\sqrt[\star]{J_n(\lambda)}$ exists if and only if $|\lambda| = 1$ when the involution on $\mathbb{C}$ is complex conjugation, and $\lambda = (-1)^{n+1}$ when the involution on $\mathbb{C}$ is the identity. Respectively, one can take $\sqrt[*]{J_n(\lambda)} = \sqrt{\lambda}\Delta_n$ and $\sqrt[T]{J_n((-1)^{n+1})} = \Gamma_n$, where

$$\Gamma_n := \begin{bmatrix} 0 & & & & \iddots \\ & & & -1 & \iddots \\ & & 1 & 1 & \\ & -1 & -1 & & \\ 1 & 1 & & & 0 \end{bmatrix}, \qquad \Delta_n := \begin{bmatrix} 0 & & & 1 \\ & & \iddots & i \\ & 1 & \iddots & \\ 1 & i & & 0 \end{bmatrix} \quad (n\text{-by-}n).$$

Using (i)–(iii), we obtain the following canonical forms of a square complex matrix A under *congruence and congruence:

- A is *congruent to a direct sum, uniquely determined up to permutation of summands, of matrices of the form $\left[\begin{smallmatrix} 0 & I_n \\ J_n(\lambda) & 0 \end{smallmatrix}\right]$, $\mu\Delta_n$, $J_n(0)$, in which $|\lambda| > 1$ and $|\mu| = 1$;
- A is congruent to a direct sum, uniquely determined up to permutation of summands, of matrices of the form $\left[\begin{smallmatrix} 0 & I_n \\ J_n(\lambda) & 0 \end{smallmatrix}\right]$, Γ_n, $J_n(0)$, in which $0 \neq \lambda \neq (-1)^{n+1}$ and λ is determined up to replacement by λ^{-1}.

Max-plus or tropical algebra has been discovered more or less independently by several schools, in relation with various mathematical fields. This chapter is limited to finite dimensional linear algebra. For more information, the reader may consult the books [CG79], [Zim81], [CKR84], [BCOQ92], [KM97], [GM02], [HOvdW05], and [But10]. The collections of articles [MS92], [Gun98], [LM05], and [LS09] give some idea of current developments. A number of recent results relevant to linear algebra have appeared in the field of tropical geometry, especially in relation with tropical convexity, we refer the reader to [RGST05], [IMS09] for general introductions.

35.1 Preliminaries

Definitions:

The **max-plus semiring** $\mathbb{R}_{\max}$ is the set $\mathbb{R}\cup\{-\infty\}$, equipped with the **addition** $(a,b)\mapsto\max(a,b)$ and the **multiplication** $(a,b)\mapsto a+b$. The identity element for the addition, **zero**, is $-\infty$, and the identity element for the multiplication, **unit**, is 0. To illuminate the linear algebraic nature of the results, the generic notations $\oplus$, $\sum$, $\otimes$ (or concatenation), $\mathbb{0}$ and $\mathbb{1}$ are used for the addition, the sum, the multiplication, the zero, and the unit of $\mathbb{R}_{\max}$, respectively, so that when a,b belong to $\mathbb{R}_{\max}$, $a\oplus b$ will mean $\max(a,b)$, $a\otimes b$ or ab will mean the usual sum $a+b$. We use blackboard (double struck) fonts to denote the max-plus operations (compare "$\oplus$" with "$+$").

The **min-plus semiring** $\mathbb{R}_{\min}$ is the set $\mathbb{R}\cup\{+\infty\}$ equipped with the addition $(a,b)\mapsto\min(a,b)$ and the multiplication $(a,b)\mapsto a+b$. The zero is $+\infty$, the unit 0.

Any submonoid $(M,+)$ of $\mathbb{R}$ yields a subsemiring $M_{\max}$ of $\mathbb{R}_{\max}$, consisting of the elements in $M\cup\{-\infty\}$. For instance, $\mathbb{Q}_{\max}$ consists of the rational elements of $\mathbb{R}_{\max}$, together with the $-\infty$ element. The subsemiring $M_{\min}$ of $\mathbb{R}_{\min}$ is defined in a similar way.

The name **tropical** is now used as a general name for algebraic structures of this kind: the max-plus and min-plus semirings are both models of tropical structures. Originally, the term "tropical" was used in a specialized sense, to refer to the subsemiring $\mathbb{N}_{\min}$ of $\mathbb{R}_{\min}$. The latter was named "tropical" in the honor of Imre Simon, who lived in Sao Paulo (south tropic) and used this semiring to solve a long standing problem in language theory [Sim78].

The **completed max-plus semiring** $\overline{\mathbb{R}}_{\max}$ is the set $\mathbb{R} \cup \{\pm\infty\}$ equipped with the addition $(a, b) \mapsto \max(a, b)$ and the multiplication $(a, b) \mapsto a + b$, with the convention that $-\infty + (+\infty) = +\infty + (-\infty) = -\infty$. The **completed min-plus semiring**, $\overline{\mathbb{R}}_{\min}$, is defined in a dual way.

Many classical algebraic definitions have max-plus analogues. For instance, $\mathbb{R}^n_{\max}$ is the set of n-dimensional **vectors** and $\mathbb{R}^{n\times p}_{\max}$ is the set of $n \times p$ **matrices** with entries in $\mathbb{R}_{\max}$. They are equipped with the vector and matrix operations, defined and denoted in the usual way. The $n \times p$ **zero matrix**, $\mathbf{0}_{np}$ or $\mathbf{0}$, has all its entries equal to $\mathbb{0}$. The $n \times n$ **identity matrix**, I_n or I, has diagonal entries equal to $\mathbb{1}$, and nondiagonal entries equal to $\mathbb{0}$. Given a matrix $A = (A_{ij}) \in \mathbb{R}^{n\times p}_{\max}$, we denote by $A_{i\cdot}$ and $A_{\cdot j}$ the i-th row and the j-th column of A. We also denote by A the linear map $\mathbb{R}^p_{\max} \to \mathbb{R}^n_{\max}$ sending a vector x to Ax. **Semimodules** and **subsemimodules** over the semiring $\mathbb{R}_{\max}$ are defined as the analogues of modules and submodules over rings. A subset F of a semimodule M over $\mathbb{R}_{\max}$ **spans** M, or is a **spanning family** of M, if every element $\mathbf{x}$ of M can be expressed as a finite linear combination of the elements of F, meaning that $\mathbf{x} = \sum_{\mathbf{f}\in F} \lambda_{\mathbf{f}}.\mathbf{f}$, where $(\lambda_{\mathbf{f}})_{\mathbf{f}\in F}$ is a family of elements of $\mathbb{R}_{\max}$ such that $\lambda_{\mathbf{f}} = \mathbb{0}$ for all but finitely many $\mathbf{f} \in F$. A semimodule is **finitely generated** if it has a finite spanning family.

The sets $\mathbb{R}_{\max}$ and $\overline{\mathbb{R}}_{\max}$ are ordered by the usual order of $\mathbb{R} \cup \{\pm\infty\}$. Vectors and matrices over $\overline{\mathbb{R}}_{\max}$ are ordered with the product ordering. The supremum and the infimum operations are denoted by $\vee$ and $\wedge$, respectively. Moreover, the sum of the elements of an arbitrary set X of scalars, vectors, or matrices with entries in $\overline{\mathbb{R}}_{\max}$ is by definition the supremum of X.

If $A \in \overline{\mathbb{R}}^{n\times n}_{\max}$, the **Kleene star** of A is the matrix $A^\star = I \oplus A \oplus A^2 \oplus \cdots$.

The **digraph** $\Gamma(A)$ associated to an $n \times n$ matrix A with entries in $\overline{\mathbb{R}}_{\max}$ consists of the vertices $1, \ldots, n$, with an arc from vertex i to vertex j when $A_{ij} \neq \mathbb{0}$. The **weight** of a walk W given by $(i_1, i_2), \ldots, (i_{k-1}, i_k)$ is $|W|_A := A_{i_1 i_2} \cdots A_{i_{k-1} i_k}$, and its **length** is $|W| := k - 1$. The matrix A is **irreducible** if $\Gamma(A)$ is strongly connected.

Facts:

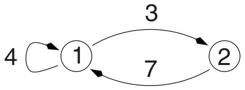
1. When $A \in \overline{\mathbb{R}}^{n\times n}_{\max}$, the weight of a walk $W = ((i_1, i_2), \ldots, (i_{k-1}, i_k))$ in $\Gamma(A)$ is given by the usual sum $|W|_A = A_{i_1 i_2} + \cdots + A_{i_{k-1} i_k}$, and $A^\star_{ij}$ gives the maximal weight $|W|_A$ of a walk from vertex i to vertex j. One can also define the matrix $A^\star$ when $A \in \overline{\mathbb{R}}^{n\times n}_{\min}$. Then, $A^\star_{ij}$ is the minimal weight of a walk from vertex i to vertex j. Computing $A^\star$ is the same as the all pairs' shortest path problem.
2. [CG79], [BCOQ92, Th. 3.20] If $A \in \overline{\mathbb{R}}^{n\times n}_{\max}$ and the weights of the cycles of $\Gamma(A)$ do not exceed $\mathbb{1}$, then $A^\star = I \oplus A \oplus \cdots \oplus A^{n-1}$.
3. [BCOQ92, Th. 4.75 and Rk. 80] If $A \in \overline{\mathbb{R}}^{n\times n}_{\max}$ and $\mathbf{b} \in \overline{\mathbb{R}}^{n}_{\max}$, then the smallest $\mathbf{x} \in \overline{\mathbb{R}}^{n}_{\max}$ such that $\mathbf{x} = A\mathbf{x} \oplus \mathbf{b}$ coincides with the smallest $\mathbf{x} \in \overline{\mathbb{R}}^{n}_{\max}$ such that $\mathbf{x} \geq A\mathbf{x} \oplus \mathbf{b}$, and it is given by $A^\star\mathbf{b}$.
4. [BCOQ92, Th. 3.17] When $A \in \mathbb{R}^{n\times n}_{\max}$, $\mathbf{b} \in \mathbb{R}^{n}_{\max}$, and when all the cycles of $\Gamma(A)$ have a weight strictly less than $\mathbb{1}$, then $A^\star\mathbf{b}$ is the unique solution $\mathbf{x} \in \mathbb{R}^n_{\max}$ of $\mathbf{x} = A\mathbf{x} \oplus \mathbf{b}$.
5. Let $A \in \mathbb{R}^{n\times n}_{\max}$ and $\mathbf{b} \in \mathbb{R}^{n}_{\max}$. Construct the sequence:
$$\mathbf{x}_0 = \mathbf{b},\ \mathbf{x}_1 = A\mathbf{x}_0 \oplus \mathbf{b},\ \mathbf{x}_2 = A\mathbf{x}_1 \oplus \mathbf{b}, \ldots.$$
The sequence $\mathbf{x}_k$ is nondecreasing. If all the cycles of $\Gamma(A)$ have a weight less than or equal to $\mathbb{1}$, then, $\mathbf{x}_{n-1} = \mathbf{x}_n = \cdots = A^\star\mathbf{b}$. Otherwise, $\mathbf{x}_{n-1} \neq \mathbf{x}_n$. Computing the sequence $\mathbf{x}_k$ to determine $A^\star\mathbf{b}$ is a special instance of label correcting shortest path algorithm [GP88].
6. [BCOQ92, Lemma 4.101] For all $a \in \overline{\mathbb{R}}^{n\times n}_{\max}, b \in \overline{\mathbb{R}}^{n\times p}_{\max}, c \in \overline{\mathbb{R}}^{p\times n}_{\max}$, and $d \in \overline{\mathbb{R}}^{p\times p}_{\max}$, we have
$$\begin{bmatrix} a & b \\ c & d \end{bmatrix}^\star = \begin{bmatrix} a^\star \oplus a^\star b(ca^\star b \oplus d)^\star ca^\star & a^\star b(ca^\star b \oplus d)^\star \\ (ca^\star b \oplus d)^\star ca^\star & (ca^\star b \oplus d)^\star \end{bmatrix}.$$

This fact and the next one are special instances of well-known results of language theory [Eil74], concerning unambiguous rational identities. Both are valid in more general semirings.

7. [MY60] Let $A \in \overline{\mathbb{R}}_{\max}^{n\times n}$. Construct the sequence of matrices $A^{(0)}, \ldots, A^{(n)}$ such that $A^{(0)} = A$ and
$$A_{ij}^{(k)} = A_{ij}^{(k-1)} \oplus A_{ik}^{(k-1)}(A_{kk}^{(k-1)})^{\star} A_{kj}^{(k-1)},$$
for $i, j = 1, \ldots, n$ and $k = 1, \ldots, n$. Then, $A^{(n)} = A \oplus A^2 \oplus \cdots$.

Examples:

1. Consider the matrix
$$A = \begin{bmatrix} 4 & 3 \\ 7 & -\infty \end{bmatrix}.$$
The digraph $\Gamma(A)$ is



We have
$$A^2 = \begin{bmatrix} 10 & 7 \\ 11 & 10 \end{bmatrix}.$$
For instance, $A_{11}^2 = A_{1\cdot}.A_{\cdot 1} = [4\ 3][4\ 7]^T = \max(4+4, 3+7) = 10$. This gives the maximal weight of a walk of length 2 from vertex 1 to vertex 1, which is attained by the walk $(1, 2), (2, 1)$. Since there is one cycle with positive weight in $\Gamma(A)$ (for instance, the cycle $(1, 1)$ has weight 4), and since A is irreducible, the matrix $A^{\star}$ has all its entries equal to $+\infty$. To get a Kleene star with finite entries, consider the matrix
$$C = (-5)A = \begin{bmatrix} -1 & -2 \\ 2 & -\infty \end{bmatrix}.$$
The only cycles in $\Gamma(A)$ are $(1, 1)$ and $(1, 2), (2, 1)$ (up to a cyclic conjugacy). They have weights -1 and 0. Applying Fact 2, we get
$$C^{\star} = I \oplus C = \begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix}.$$

Applications:

1. *Dynamic programming.* Consider a deterministic Markov decision process with a set of states $\{1, \ldots, n\}$ in which one player can move from state i to state j, receiving a payoff of $A_{ij} \in \mathbb{R} \cup \{-\infty\}$. To every state i, associate an initial payoff $\mathbf{c}_i \in \mathbb{R} \cup \{-\infty\}$ and a terminal payoff $\mathbf{b}_i \in \mathbb{R} \cup \{-\infty\}$. The value in horizon k is by definition the maximum of the sums of the payoffs (including the initial and terminal payoffs) corresponding to all the trajectories consisting exactly of k moves. It is given by $\mathbf{c}A^k\mathbf{b}$, where the product and the power are understood in the max-plus sense. The special case where the initial state is equal to some given $m \in \{1, \ldots, n\}$ (and where there is no initial payoff) can be modeled by taking $\mathbf{c} := \mathbf{e}_m$, the m-th max-plus basis vector (whose entries are all equal to $\mathbb{0}$, except the m-th entry, which is equal to $\mathbb{1}$). The case where the final state is fixed can be represented in a dual way. Deterministic Markov decision problems (which are the same as shortest path problems) are ubiquitous in operations research, mathematical economics, and optimal control.
2. [BCOQ92] *Discrete event systems.* Consider a system in which certain repetitive events, denoted by $1, \ldots, n$, occur. To every event i is associated a dater function $x_i : \mathbb{Z} \to \mathbb{R}$, where $x_i(k)$ represents the date of the k-th occurrence of event i. Precedence constraints

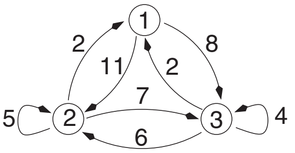
between the repetitive events are given by a set of arcs $E \subset \{1,\dots,n\}^2$, equipped with two valuations $\nu : E \to \mathbb{N}$ and $\tau : E \to \mathbb{R}$. If $(i,j) \in E$, the k-th execution of event i cannot occur earlier than τ_{ij} time units before the $(k-\nu_{ij})$-th execution of event j, so that $x_i(k) \geq \max_{j\colon (i,j)\in E} \tau_{ij} + x_j(k-\nu_{ij})$. This can be rewritten, using the max-plus notation, as

$$\mathbf{x}(k) \geq A_0\mathbf{x}(k) \oplus \cdots \oplus A_{\bar\nu}\mathbf{x}(k-\bar\nu),$$

where $\bar\nu := \max_{(i,j)\in E} \nu_{ij}$ and $\mathbf{x}(k) \in \mathbb{R}^n_{\max}$ is the vector with entries $x_i(k)$. Often, the dates $x_i(k)$ are only defined for positive k, then appropriate initial conditions must be incorporated in the model. One is particularly interested in the earliest dynamics, which, by Fact 3, is given by $\mathbf{x}(k) = A_0^\star A_1\mathbf{x}(k-1) \oplus \cdots \oplus A_0^\star A_{\bar\nu}\mathbf{x}(k-\bar\nu)$. The class of systems following dynamics of these forms is known in the Petri net literature as **timed event graphs**. It is used to model certain manufacturing systems [CDQV85], or transportation or communication networks [BCOQ92], [HOvdW05].

3. Bacaër [Bac03] observed that max-plus algebra appears in a familiar problem – crop rotation. Suppose n different crops can be cultivated every year. Assume for simplicity that the income of the year is a deterministic function, $(i,j) \mapsto A_{ij}$, depending only on the crop i of the preceding year, and of the crop j of the current year (a slightly more complex model in which the income of the year depends on the crops of the two preceding years is needed to explain the historical variations of crop rotations [Bac03]). The income of a sequence $i_1,\dots,i_k$ of crops can be written as $\mathbf{c}_{i_1}A_{i_1i_2}\cdots A_{i_{k-1}i_k}$, where $\mathbf{c}_{i_1}$ is the income of the first year. The maximal income in k years is given by $\mathbf{c}A^{k-1}\mathbf{b}$, where $\mathbf{b} = (\mathbb{1},\dots,\mathbb{1})$. We next show an example.

$$A = \begin{bmatrix} -\infty & 11 & 8 \\ 2 & 5 & 7 \\ 2 & 6 & 4 \end{bmatrix}$$



Here, vertices 1, 2, and 3 represent fallow (no crop), wheat, and oats, respectively. (We put no arc from 1 to 1, setting $A_{11} = -\infty$, to disallow two successive years of fallow.) The numerical values have no pretension to realism; however, the income of a year of wheat is 11 after a year of fallow; this is greater than after a year of cereal (5 or 6, depending on whether wheat or oats was cultivated). An initial vector coherent with these data may be $\mathbf{c} = [-\infty\ 11\ 8]$, meaning that the income of the first year is the same as the income after a year of fallow. We have $\mathbf{c}A\mathbf{b} = 18$, meaning that the optimal income in 2 years is 18. This corresponds to the optimal walk $(2,3)$, indicating that wheat and oats should be successively cultivated during these 2 years.

35.2 The Maximal Cycle Mean

Definitions:

The **maximal cycle mean**, $\rho_{\max}(A)$, of a matrix $A \in \mathbb{R}^{n\times n}_{\max}$, is the maximum of the weight-to-length ratio over all cycles c of $\Gamma(A)$, that is,

$$\rho_{\max}(A) = \max_{c \text{ cycle of } \Gamma(A)} \frac{|c|_A}{|c|} = \max_{k\geq 1}\max_{i_1,\dots,i_k} \frac{A_{i_1i_2} + \cdots + A_{i_ki_1}}{k}. \tag{35.1}$$

Denote by $\mathbb{R}^{n\times n}_+$ the set of real $n\times n$ matrices with nonnegative entries. For $A \in \mathbb{R}^{n\times n}_+$ and $p > 0$, $A^{(p)}$ is by definition the matrix such that $(A^{(p)})_{ij} = (A_{ij})^p$, and

$$\rho_p(A) := (\rho(A^{(p)}))^{1/p},$$

where ρ denotes the (usual) spectral radius. We also define $\rho_\infty(A) = \lim_{p\to+\infty}\rho_p(A)$.

Facts:

1. [CG79], [Gau92, Ch. IV], [BSvdD95] *Max-plus Collatz–Wielandt formula, I.* Let $A \in \mathbb{R}_{\max}^{n \times n}$ and $\lambda \in \mathbb{R}$. The following assertions are equivalent: (i) There exists $\mathbf{u} \in \mathbb{R}^n$ such that $A\mathbf{u} \leq \lambda \mathbf{u}$; (ii) $\rho_{\max}(A) \leq \lambda$. It follows that
$$\rho_{\max}(A) = \inf_{\mathbf{u} \in \mathbb{R}^n} \max_{1 \leq i \leq n} (A\mathbf{u})_i \mathbin{/\!\!/} \mathbf{u}_i$$
(the product $A\mathbf{u}$ and the division by $\mathbf{u}_i$ should be understood in the max-plus sense). If $\rho_{\max}(A) > \mathbb{0}$, then this infimum is attained by some $\mathbf{u} \in \mathbb{R}^n$. If in addition A is irreducible, then Assertion (i) is equivalent to the following: (i') there exists $\mathbf{u} \in \mathbb{R}_{\max}^n \setminus \{\mathbf{0}\}$ such that $A\mathbf{u} \leq \lambda \mathbf{u}$.
2. [Gau92, Ch. IV], [BSvdD95] *Max-plus Collatz–Wielandt formula, II.* Let $\lambda \in \mathbb{R}_{\max}$. The following assertions are equivalent: (i) There exists $\mathbf{u} \in \mathbb{R}_{\max}^n \setminus \{\mathbf{0}\}$ such that $A\mathbf{u} \geq \lambda \mathbf{u}$; (ii) $\rho_{\max}(A) \geq \lambda$. It follows that
$$\rho_{\max}(A) = \max_{\mathbf{u} \in \mathbb{R}_{\max}^n \setminus \{\mathbf{0}\}} \min_{\substack{1 \leq i \leq n \\ \mathbf{u}_i \neq \mathbb{0}}} (A\mathbf{u})_i \mathbin{/\!\!/} \mathbf{u}_i.$$
3. [Fri86] For $A \in \mathbb{R}_+^{n \times n}$, we have $\rho_\infty(A) = \exp(\rho_{\max}(\log(A)))$, where log is interpreted entrywise.
4. [KO85] For all $A \in \mathbb{R}_+^{n \times n}$, and $1 \leq q \leq p \leq \infty$, we have $\rho_p(A) \leq \rho_q(A)$.
5. For all $A, B \in \mathbb{R}_+^{n \times n}$, we have
$$\rho(A \circ B) \leq \rho_p(A)\rho_q(B) \quad \text{for all} \quad p, q \in [1, \infty] \quad \text{such that} \quad \frac{1}{p} + \frac{1}{q} = 1.$$
This follows from the classical Kingman's inequality [Kin61], which states that the map $\log \circ \rho \circ \exp$ is convex (exp is interpreted entrywise). We have in particular $\rho(A \circ B) \leq \rho_\infty(A)\rho(B)$.
6. [Fri86] For all $A \in \mathbb{R}_+^{n \times n}$, we have
$$\rho_\infty(A) \leq \rho(A) \leq \rho_\infty(A)\rho(\hat{A}) \leq \rho_\infty(A)n,$$
where $\hat{A}$ is the pattern matrix of A, that is, $\hat{A}_{ij} = 1$ if $A_{ij} \neq 0$ and $\hat{A}_{ij} = 0$ if $A_{ij} = 0$.
7. [Bap98], [EvdD99] For all $A \in \mathbb{R}_+^{n \times n}$, we have $\lim_{k \to \infty} (\rho_\infty(A^k))^{1/k} = \rho(A)$.
8. [CG79] *Computing $\rho_{\max}(A)$ by linear programming.* For $A \in \mathbb{R}_{\max}^{n \times n}$, $\rho_{\max}(A)$ is the value of the linear program
$$\inf \lambda \text{ s.t. } \exists \mathbf{u} \in \mathbb{R}^n, \quad \forall (i,j) \in E, \quad A_{ij} + \mathbf{u}_j \leq \lambda + \mathbf{u}_i,$$
where $E = \{(i,j) \mid 1 \leq i, j \leq n, \ A_{ij} \neq \mathbb{0}\}$ is the set of arcs of $\Gamma(A)$.
9. *Dual linear program to compute $\rho_{\max}(A)$.* Let $\mathcal{C}$ denote the set of nonnegative vectors $x = (x_{ij})_{(i,j) \in E}$ such that
$$\forall 1 \leq i \leq n, \quad \sum_{1 \leq k \leq n, \ (k,i) \in E} x_{ki} = \sum_{1 \leq j \leq n, (i,j) \in E} x_{ij}, \quad \text{and} \quad \sum_{(i,j) \in E} x_{ij} = 1.$$
To every cycle c of $\Gamma(A)$ corresponds bijectively the extreme point of the polytope $\mathcal{C}$ that is given by $x_{ij} = 1/|c|$ if (i,j) belongs to c, and $x_{ij} = 0$ otherwise. Moreover, $\rho_{\max}(A) = \sup\{\sum_{(i,j) \in E} A_{ij} x_{ij} \mid x \in \mathcal{C}\}$.
10. [Kar78] *Karp's formula.* If $A \in \mathbb{R}_{\max}^{n \times n}$ is irreducible, then, for all $1 \leq i \leq n$,

$$\rho_{\max}(A) = \max_{\substack{1\leq j\leq n\\ A^n_{ij}\neq \mathbb{0}}} \min_{1\leq k\leq n} \frac{(A^n)_{ij} - (A^{n-k})_{ij}}{k}. \qquad (35.2)$$

To evaluate the right-hand side expression, compute the sequence $\mathbf{u}^0 = \mathbf{e}_i$, $\mathbf{u}^1 = \mathbf{u}^0 A$, $\mathbf{u}^n = \mathbf{u}^{n-1}A$, so that $\mathbf{u}^k = A^k_{i\cdot}$ for all $0 \leq k \leq n$. This takes a time $O(nm)$, where m is the number of arcs of $\Gamma(A)$. One can avoid storing the vectors $\mathbf{u}^0, \dots, \mathbf{u}^n$, at the price of recomputing the sequence $\mathbf{u}^0, \dots, \mathbf{u}^{n-1}$ once $\mathbf{u}^n$ is known. The time and space complexity of Karp's algorithm are $O(nm)$ and $O(n)$, respectively. The policy iteration algorithm of [CTCG$^+$98] seems experimentally more efficient than Karp's algorithm. Other algorithms are given in particular in [CGL96], [BO93], and [EvdD99]. A comparison of maximal cycle mean algorithms appears in [DGI98]. When the entries of A take only two finite values, the maximal cycle mean of A can be computed in linear time [CGB95]. The Karp and policy iteration algorithms, as well as the general max-plus operations (full and sparse matrix products, matrix residuation, etc.) are implemented in the `Maxplus toolbox` which can be used in `Scilab` and `Scicoslab`, see `www.scicoslab.org`.

Examples:

1. For the matrix A in Application 35.1.3, we have $\rho_{\max}(A) = \max(5, 4, (2{+}11)/2, (2{+}8)/2, (7+6)/2, (11+7+2)/3, (8+6+2)/3) = 20/3$, which gives the maximal reward per year. This is attained by the cycle $(1,2), (2,3), (3,1)$, corresponding to the rotation of crops: fallow, wheat, oats.

35.3 The Max-Plus Eigenproblem

The results of this section and of the next one constitute max-plus spectral theory. Early and fundamental contributions are due to Cuninghame–Green (see [CG79]), Vorobyev [Vor67], Romanovskiĭ [Rom67], Gondran and Minoux [GM77], and Cohen, Dubois, Quadrat, and Viot [CDQV83]. General presentations can be found in [CG79], [BCOQ92], [GM02], [HOvdW05], and [But10]. The infinite dimensional max-plus spectral theory (which is not covered here) has been developed particularly after Maslov, in relation with Hamilton–Jacobi partial differential equations; see [MS92] and [KM97]. See also [MPN02], [AGW05], [AGW09], [FS05], and [Fat12] for recent developments.

In this section and in the next two sections, A denotes a matrix in $\mathbb{R}^{n\times n}_{\max}$.

Definitions:

An **eigenvector** of A is a vector $\mathbf{u} \in \mathbb{R}^n_{\max} \setminus \{\mathbf{0}\}$ such that $A\mathbf{u} = \lambda\mathbf{u}$, for some scalar $\lambda \in \mathbb{R}_{\max}$, which is called the **(geometric) eigenvalue** corresponding to $\mathbf{u}$. With the notation of classical algebra, the equation $A\mathbf{u} = \lambda\mathbf{u}$ can be rewritten as

$$\max_{1\leq j\leq n} A_{ij} + \mathbf{u}_j = \lambda + \mathbf{u}_i, \quad \forall 1 \leq i \leq n.$$

If λ is an eigenvalue of A, the set of vectors $\mathbf{u} \in \mathbb{R}^n_{\max}$ such that $A\mathbf{u} = \lambda\mathbf{u}$ is the **eigenspace** of A for the eigenvalue λ.

The **saturation digraph** with respect to $\mathbf{u} \in \mathbb{R}^n_{\max}$, $\operatorname{Sat}(A, \mathbf{u})$, is the digraph with vertices $1, \dots, n$ and an arc from vertex i to vertex j when $A_{ij}\mathbf{u}_j = (A\mathbf{u})_i$.

A cycle $c = (i_1, i_2), \dots, (i_k, i_1)$ that attains the maximum in Eq. (35.1) is called **critical**. The **critical digraph** is the union of the critical cycles. The **critical vertices** are the vertices of the critical digraph.

The **normalized matrix** is $\tilde{A} = \rho_{\max}(A)^{-1}A$ (when $\rho_{\max}(A) \neq \mathbb{0}$).

For a digraph Γ, vertex i **has access** to a vertex j if there is a walk from i to j in Γ. The **(access equivalent) classes** of Γ are the equivalence classes of the set of its vertices for the relation "i has access to j and j has access to i." A class C **has access** to a class C' if some vertex of C has access to some vertex of C'. A class is **final** if it has access only to itself.

The **classes** of a matrix A are the classes of $\Gamma(A)$, and the **critical classes** of A are the classes of the critical digraph of A. A class C of A is **basic** if $\rho_{\max}(A[C,C]) = \rho_{\max}(A)$.

Facts:

The proof of most of the following facts can be found in particular in [CG79], [BCOQ92, Sect. 3.7], [HOvdW05], or [But10]; we give specific references when needed.

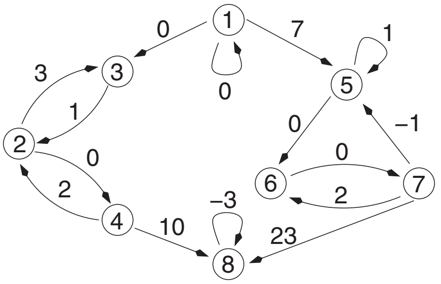
1. For any matrix A, $\rho_{\max}(A)$ is an eigenvalue of A, and any eigenvalue of A is less than or equal to $\rho_{\max}(A)$.
2. An eigenvalue of A associated with an eigenvector in $\mathbb{R}^n$ must be equal to $\rho_{\max}(A)$.
3. [ES75] *Max-plus diagonal scaling.* Assume that $\mathbf{u} \in \mathbb{R}^n$ is an eigenvector of A. Then the matrix B such that $B_{ij} = \mathbf{u}_i^{-1} A_{ij} \mathbf{u}_j$ has all its entries less than or equal to $\rho_{\max}(A)$, and the maximum of every row is equal to $\rho_{\max}(A)$.
4. If A is irreducible, then $\rho_{\max}(A) > \mathbb{0}$ and it is the only eigenvalue of A. *From now on, we assume that $\Gamma(A)$ has at least one cycle, so that $\rho_{\max}(A) > \mathbb{0}$.*
5. For all critical vertices i of A, the column $\tilde{A}^\star_{\cdot i}$ is an eigenvector of A for the eigenvalue $\rho_{\max}(A)$. Moreover, if i and j belong to the same critical class of A, then $\tilde{A}^\star_{\cdot i} = \tilde{A}^\star_{\cdot j} \tilde{A}^\star_{ji}$.
6. *Eigenspace for the eigenvalue $\rho_{\max}(A)$.* Let $C_1, \ldots, C_s$ denote the critical classes of A, and let us choose arbitrarily one vertex $i_t \in C_t$, for every $t = 1, \ldots, s$. Then, the columns $\tilde{A}^\star_{\cdot, i_t}$, $t = 1, \ldots, s$ span the eigenspace of A for the eigenvalue $\rho_{\max}(A)$. Moreover, any spanning family of this eigenspace contains some scalar multiple of every column $\tilde{A}^\star_{\cdot, i_t}$, $t = 1, \ldots, s$.
7. Let C denote the set of critical vertices, and let $T = \{1, \ldots, n\} \setminus C$. The following facts are proved in a more general setting in [AG03, Th. 3.4], with the exception of (b), which follows from Fact 35.1.4.
   (a) The restriction $\mathbf{v} \mapsto \mathbf{v}[C]$ is an isomorphism from the eigenspace of A for the eigenvalue $\rho_{\max}(A)$ to the eigenspace of $A[C,C]$ for the same eigenvalue.
   (b) An eigenvector $\mathbf{u}$ for the eigenvalue $\rho_{\max}(A)$ is determined from its restriction $\mathbf{u}[C]$ by $\mathbf{u}[T] = (\tilde{A}[T,T])^\star \tilde{A}[T,C] \mathbf{u}[C]$.
   (c) Moreover, $\rho_{\max}(A)$ is the only eigenvalue of $A[C,C]$ and the eigenspace of $A[C,C]$ is stable by infimum and by convex combination in the usual sense.
8. *Complementary slackness.* If $\mathbf{u} \in \mathbb{R}^n_{\max}$ is such that $A\mathbf{u} \leq \rho_{\max}(A)\mathbf{u}$, then $(A\mathbf{u})_i = \rho_{\max}(A)\mathbf{u}_i$, for all critical vertices i.
9. *Critical digraph vs. saturation digraph.* Let $\mathbf{u} \in \mathbb{R}^n$ be such that $A\mathbf{u} \leq \rho_{\max}(A)\mathbf{u}$. Then, the union of the cycles of $\mathrm{Sat}(A, \mathbf{u})$ is equal to the critical digraph of A.
10. [CQD90], [Gau92, Ch. IV], [BSvdD95], [BCGG09] *Spectrum of reducible matrices.* A scalar $\lambda \neq \mathbb{0}$ is an eigenvalue of A if and only if there is at least one class C of A such that $\rho_{\max}(A[C,C]) = \lambda$ and $\rho_{\max}(A[C,C]) \geq \rho_{\max}(A[C',C'])$ for all classes C' that have access to C.
11. [CQD90], [BSvdD95], [BCGG09] The matrix A has an eigenvector in $\mathbb{R}^n$ if and only if all its final classes are basic.
12. [Gau92, Ch. IV], [BCGG09] *Eigenspace for an eigenvalue λ.* Let $C^1, \ldots, C^m$ denote all the classes C of A such that $\rho_{\max}(A[C,C]) = \lambda$ and $\rho_{\max}(A[C',C']) \leq \lambda$ for all classes C' that have access to C. For every $1 \leq k \leq m$, let $C^k_1, \ldots, C^k_{s_k}$ denote the critical classes of the matrix $A[C^k, C^k]$. For all $1 \leq k \leq m$ and $1 \leq t \leq s_k$, let us choose arbitrarily an element $j_{k,t}$ in C^k_t. Then, the family of columns $(\lambda^{-1}A)^\star_{\cdot, j_{k,t}}$, indexed by all these k and t, spans the eigenspace of A for the eigenvalue λ, and any spanning family of this eigenspace contains a scalar multiple of every $(\lambda^{-1}A)^\star_{\cdot, j_{k,t}}$.

13. *Computing the eigenvectors.* Observe first that any vertex j that attains the maximum in Karp's formula (35.2) is critical. To compute one eigenvector for the eigenvalue $\rho_{\max}(A)$, it suffices to compute $\tilde{A}^{\star}_{\cdot j}$ for some critical vertex j. This is equivalent to a single source shortest path problem, which can be solved in $O(nm)$ time and $O(n)$ space. Alternatively, one may use the *policy iteration algorithm* of [CTCG$^+$98] or the improvement in [EvdD99] of the *power algorithm* [BO93]. Once a particular eigenvector is known, the critical digraph can be computed from Fact 9 in $O(m)$ additional time.

Examples:

1. For the matrix A in Application 35.1.3, the only critical cycle is $(1,2),(2,3),(3,1)$ (up to a circular permutation of vertices). The critical digraph consists of the vertices and arcs of this cycle. By Fact 6, any eigenvector $\mathbf{u}$ of A is proportional to $\tilde{A}^{\star}_{\cdot 1} = [0\ {-13/3}\ {-14/3}]^T$ (or equivalently, to $\tilde{A}^{\star}_{\cdot 2}$ or $\tilde{A}^{\star}_{\cdot 3}$). Observe that an eigenvector yields a relative price information between the different states.
2. Consider the matrix and its associated digraph:

$$A = \left[\begin{array}{c|ccc|ccc|c}
0 & \cdot & 0 & \cdot & 7 & \cdot & \cdot & \cdot \\
\hline
\cdot & \cdot & 3 & 0 & \cdot & \cdot & \cdot & \cdot \\
\cdot & 1 & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & 2 & \cdot & \cdot & \cdot & \cdot & \cdot & 10 \\
\hline
\cdot & \cdot & \cdot & \cdot & 1 & 0 & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & 0 & \cdot \\
\cdot & \cdot & \cdot & \cdot & -1 & 2 & \cdot & 23 \\
\hline
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & -3
\end{array}\right]$$



(We use $\cdot$ to represent the element $-\infty$.) The classes of A are $C^1 = \{1\}$, $C^2 = \{2,3,4\}$, $C^3 = \{5,6,7\}$, and $C^4 = \{8\}$. We have $\rho_{\max}(A) = \rho_{\max}(A[C^2,C^2]) = 2$, $\rho_{\max}(A[C^1,C^1]) = 0$, $\rho_{\max}(A[C^3,C^3]) = 1$, and $\rho_{\max}(A[C^4,C^4]) = -3$. The critical digraph is reduced to the critical cycle $(2,3)(3,2)$. By Fact 6, any eigenvector for the eigenvalue $\rho_{\max}(A)$ is proportional to $\tilde{A}^{\star}_{\cdot 2} = [-3\ 0\ -1\ 0\ -\infty\ -\infty\ -\infty\ -\infty]^T$. By Fact 10, the other eigenvalues of A are 0 and 1. By Fact 12, any eigenvector for the eigenvalue 0 is proportional to $A^{\star}_{\cdot 1} = \mathbf{e}_1$. Observe that the critical classes of $A[C^3,C^3]$ are $C^3_1 = \{5\}$ and $C^3_2 = \{6,7\}$. Therefore, by Fact 12, any eigenvector for the eigenvalue 1 is a max-plus linear combination of $(1^{-1}A)^{\star}_{\cdot 5} = [6\ -\infty\ -\infty\ -\infty\ 0\ -3\ -2\ -\infty]^T$ and $(1^{-1}A)^{\star}_{\cdot 6} = [5\ -\infty\ -\infty\ -\infty\ -1\ 0\ 1\ -\infty]^T$. The eigenvalues of A^T are $2, 1$, and -3. So A and A^T have only two eigenvalues in common.

35.4 Asymptotics of Matrix Powers

Definitions:

A sequence $s_0, s_1, \ldots$ of elements of $\mathbb{R}_{\max}$ is **recognizable** if there exists a positive integer p, vectors $\mathbf{b} \in \mathbb{R}_{\max}^{p\times 1}$ and $\mathbf{c} \in \mathbb{R}_{\max}^{1\times p}$, and a matrix $M \in \mathbb{R}_{\max}^{p\times p}$ such that $s_k = \mathbf{c}M^k\mathbf{b}$, for all nonnegative integers k.

A sequence $s_0, s_1, \ldots$ of elements of $\mathbb{R}_{\max}$ is **ultimately geometric** with **rate** $\lambda \in \mathbb{R}_{\max}$ if $s_{k+1} = \lambda s_k$ for k large enough.

The **merge** of q sequences $s^1, \ldots, s^q$ is the sequence s such that $s_{kq+i-1} = s^i_k$, for all $k \geq 0$ and $1 \leq i \leq q$.

Facts:

1. [Gun94], [CTGG99] If every row of the matrix A has at least one entry different from $\mathbb{0}$, then, for all $1 \le i \le n$ and $\mathbf{u} \in \mathbb{R}^n$, the limit

$$\chi_i(A) = \lim_{k\to\infty} (A^k \mathbf{u})_i^{1/k}$$

exists and is independent of the choice of $\mathbf{u}$. The vector $\chi(A) = (\chi_i(A))_{1\le i\le n} \in \mathbb{R}^n$ is called the *cycle-time* of A. It is given by

$$\chi_i(A) = \max\{\rho_{\max}(A[C,C]) \mid C \text{ is a class of } A \text{ to which } i \text{ has access}\}.$$

In particular, if A is irreducible, then $\chi_i(A) = \rho_{\max}(A)$ for all $i = 1, \ldots, n$.

2. The following constitutes the cyclicity theorem, due to Cohen et al. [CDQV83]. See [BCOQ92], [AGW05], and [HOvdW05] for accounts in English of this result.
   (a) If A is irreducible, there exists a positive integer γ such that $A^{k+\gamma} = \rho_{\max}(A)^\gamma A^k$ for k large enough. The minimal value of γ is called the **cyclicity** of A.
   (b) Assume again that A is irreducible. Let $C_1, \ldots, C_s$ be the critical classes of A, and for $i = 1, \ldots, s$, let γ_i denote the g.c.d. (greatest common divisor) of the lengths of the critical cycles of A belonging to C_i. Then, the cyclicity γ of A is the l.c.m. (least common multiple) of $\gamma_1, \ldots, \gamma_s$.
   (c) Assume that $\rho_{\max}(A) \neq \mathbb{0}$. The *spectral projector* of A is the matrix $P := \lim_{k\to\infty} \tilde{A}^k \tilde{A}^\star = \lim_{k\to\infty} \tilde{A}^k \oplus \tilde{A}^{k+1} \oplus \cdots$. It is given by $P = \bigoplus_{i\in C} \tilde{A}^\star_{\cdot i} \tilde{A}^\star_{i\cdot}$, where C denotes the set of critical vertices of A. When A is irreducible, the limit is attained in finite time. If, in addition, A has cyclicity one, then $A^k = \rho_{\max}(A)^k P$ for k large enough.

3. Assume that A is irreducible, and let m denote the number of arcs of its critical digraph. Then, the cyclicity of A can be computed in $O(m)$ time from the critical digraph of A, using the algorithm of Denardo [Den77].
4. The smallest integer k such that $A^{k+\gamma} = \rho_{\max}(A)^\gamma A^k$ is called the *coupling time*. It is estimated in [HA99], [BG01], [AGW05] (assuming again that A is irreducible). See [CBFN12] for a recent result.
5. [AGW05, Th. 7.5] *Turnpike theorem.* Define a walk of $\Gamma(A)$ to be optimal if it has a maximal weight among all walks with the same ends and length. If A is irreducible, then the number of noncritical vertices of an optimal walk (counted with multiplicities) is bounded by a constant depending only on A.
6. [Mol88], [Gau94], [KB94], [DeS00] A sequence of elements of $\mathbb{R}_{\max}$ is recognizable if and only if it is a merge of ultimately geometric sequences. In particular, for all $1 \le i, j \le n$, the sequence $(A^k)_{ij}$ is a merge of ultimately geometric sequences. Further results appeared in [SS12].
7. [Sim78], [Has90], [Sim94], [Gau96] Given p matrices, $A_1, \ldots, A_p \in \mathbb{Q}_{\max}^{n\times n}$, the following problem is decidable: is the semigroup $S := \{A_{i_1} \ldots A_{i_k} \mid 1 \le k,\ 1 \le i_1, \ldots, i_k \le p\}$ generated by these matrices finite? The following problem is also decidable: given $1 \le i, j \le n$, and S as above, is the set $\{M_{ij} \mid M \in S\}$ of (i,j)-entries of the matrices of S finite (limitedness problem)?
8. [Kro94] The following problem is undecidable: given matrices $A_1, \ldots, A_p$ as above, a scalar $\gamma \in \mathbb{Q}$, and $1 \le i, j \le n$, is there an integer k and a sequence $i_1, \ldots, i_k$ of elements of $\{1, \ldots, n\}$ such that $(A_{i_1} \ldots A_{i_k})_{ij} = \gamma$? Several other reachability problems are also undecidable [GK06].

Examples:

1. For the matrix A in Application 35.1.3, the cyclicity is 3, and the spectral projector is

$$P = \tilde{A}^\star_{\cdot 1}\tilde{A}^\star_{1\cdot} = \begin{bmatrix} 0 \\ -13/3 \\ -14/3 \end{bmatrix} \begin{bmatrix} 0 & 13/3 & 14/3 \end{bmatrix}^T = \begin{bmatrix} 0 & 13/3 & 14/3 \\ -13/3 & 0 & 1/3 \\ -14/3 & -1/3 & 0. \end{bmatrix}.$$

2. For the matrix A in Example 35.3.2, the cycle-time is $\chi(A) = [2\ 2\ 2\ 2\ 1\ 1\ 1\ -3]^T$. The cyclicity of $A[C^2, C^2]$ is 2 because there is only one critical cycle, which has length 2. Let $B := A[C^3, C^3]$. The critical digraph of B has two strongly connected components consisting, respectively, of the cycles $(5,5)$ and $(6,7),(7,6)$. So B has cyclicity l.c.m. $(1,2) = 2$. The sequence $s_k := (A^k)_{18}$ is such that $s_{k+2} = s_k + 4$, for $k \geq 24$, with $s_{24} = s_{25} = 51$. Hence, s_k is the merge of two ultimately geometric sequences, both with rate 4. To get an example where different rates appear, replace the entries A_{11} and A_{88} of A by $-\infty$. Then, the same sequence s_k is such that $s_{k+2} = s_k + 4$, for all even $k \geq 24$, and $s_{k+2} = s_k + 2$, for all odd $k \geq 5$, with $s_5 = 31$ and $s_{24} = 51$.

35.5 The Max-Plus Permanent

Definitions:

The (max-plus) **permanent** of A is

$$\operatorname{per} A = \sum_{\sigma \in S_n} |\sigma|_A, \quad \text{where} \quad |\sigma|_A := A_{1\sigma(1)} \cdots A_{n\sigma(n)} \ .$$

With the usual notation of classical algebra, $|\sigma|_A = A_{1\sigma(1)} + \cdots + A_{n\sigma(n)}$, so $\operatorname{per} A = \max_{\sigma \in S_n} |\sigma|_A$ is the value of the optimal assignment problem with weights A_{ij}.

A **max-plus polynomial function** P is a map $\mathbb{R}_{\max} \to \mathbb{R}_{\max}$ of the form $P(x) = \sum_{i=0}^{n} p_i x^i$ with $p_i \in \mathbb{R}_{\max}$, $i = 0, \ldots, n$. If $p_n \neq \mathbb{0}$, P is of **degree** n.

The **roots** of a nonzero max-plus polynomial function P are the points of nondifferentiability of P, together with the point $\mathbb{0}$ when the derivative of P near $-\infty$ is positive. The **multiplicity** of a root α of P is defined as the variation of the derivative of P at the point α, $P'(\alpha^+) - P'(\alpha^-)$, when $\alpha \neq \mathbb{0}$, and as its derivative nears $-\infty$, $P'(\mathbb{0}^+)$, when $\alpha = \mathbb{0}$.

The (max-plus) **characteristic polynomial function** of A is the polynomial function P_A given by $P_A(x) = \operatorname{per}(A \oplus xI)$ for $x \in \mathbb{R}_{\max}$. The **algebraic eigenvalues** of A are the roots of P_A.

Facts:

1. [CGM80] Any nonzero max-plus polynomial function P can be factored uniquely as $P(x) = a(x \oplus \alpha_1) \cdots (x \oplus \alpha_n)$, where $a \in \mathbb{R}$, n is the degree of P, and the α_i are the roots of P, counted with multiplicities.
2. [CG83], [ABG06, Th. 4.6 and 4.7] The greatest algebraic eigenvalue of A is equal to $\rho_{\max}(A)$. Its multiplicity is less than or equal to the number of critical vertices of A, with equality if and only if the critical vertices can be covered by disjoint critical cycles.
3. Any geometric eigenvalue of A is an algebraic eigenvalue of A. (This can be deduced from Fact 2 of this section and Fact 35.3.10.)
4. [Yoe61] If $A \geq I$ and $\operatorname{per} A = \mathbb{1}$, then $A^\star_{ij} = \operatorname{per} A(j,i)$, for all $1 \leq i, j \leq n$.
5. [But00] Assume that all the entries of A are different from $\mathbb{0}$. The following are equivalent: (i) there is a vector $b \in \mathbb{R}^n$ that has a unique pre-image by A; (ii) there

is only one permutation σ such that $|\sigma|_A = \operatorname{per} A$. Further characterizations can be found in [But00] and [DSS05].

6. [Bap95] *Alexandroff inequality over* $\mathbb{R}_{\max}$. Construct the matrix B with columns $A_{\cdot 1}$, $A_{\cdot 1}$, $A_{\cdot 3}, \dots, A_{\cdot n}$ and the matrix C with columns $A_{\cdot 2}$, $A_{\cdot 2}$, $A_{\cdot 3}, \dots, A_{\cdot n}$. Then $(\operatorname{per} A)^2 \geq (\operatorname{per} B)(\operatorname{per} C)$, or with the notation of classical algebra, $2 \times \operatorname{per} A \geq \operatorname{per} B + \operatorname{per} C$.
7. [BB03], [GK10] The max-plus characteristic polynomial function of A can be computed by solving $O(n)$ optimal assignment problems, or directely in $O(n^3)$ time by solving the corresponding parametric assignment problem.
8. [ABG04] The notion of algebraic eigenvalue can be extended to a max-plus matrix polynomial, $A_0 \oplus A_1 x \oplus \cdots \oplus A_d x^d$, where $A_0, \dots, A_d \in \mathbb{R}_{\max}^{n \times n}$. These eigenvalues can still be computed along the lines of [BB03], [GK10].

Examples:

1. For the matrix A in Example 35.3.2, the characteristic polynomial of A is the product of the characteristic polynomials of the matrices $A[C^i, C^i]$, for $i = 1, \dots, 4$. Thus, $P_A(x) = (x \oplus 0)(x \oplus 2)^2 x (x \oplus 1)^3 (x \oplus (-3))$, and so, the algebraic eigenvalues of A are $-\infty, -3, 0, 1,$and 2, with respective multiplicities 1, 1, 1, 3, and 2.

35.6 Linear Inequalities and Projections

Definitions:

If $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$, the **range** of A, denoted $\operatorname{range} A$, is $\{A\mathbf{x} \mid \mathbf{x} \in \overline{\mathbb{R}}_{\max}^{p}\} \subset \overline{\mathbb{R}}_{\max}^{n}$. The **kernel** of A, denoted $\ker A$, is the set of **equivalence classes modulo** A, which are the classes for the equivalence relation "$\mathbf{x} \sim \mathbf{y}$ if $A\mathbf{x} = A\mathbf{y}$."

The **support** of a vector $\mathbf{b} \in \overline{\mathbb{R}}_{\max}^{n}$ is $\operatorname{supp} \mathbf{b} := \{i \in \{1, \dots, n\} \mid \mathbf{b}_i \neq \mathbb{0}\}$.

The **orthogonal congruence** of a subset U of $\overline{\mathbb{R}}_{\max}^{n}$ is $U^{\perp} := \{(\mathbf{x}, \mathbf{y}) \in \overline{\mathbb{R}}_{\max}^{n} \times \overline{\mathbb{R}}_{\max}^{n} \mid \mathbf{u} \cdot \mathbf{x} = \mathbf{u} \cdot \mathbf{y} \ \forall \mathbf{u} \in U\}$, where "$\cdot$" denotes the max-plus scalar product. The **orthogonal space** of a subset C of $\overline{\mathbb{R}}_{\max}^{n} \times \overline{\mathbb{R}}_{\max}^{n}$ is $C^{\top} := \{\mathbf{u} \in \overline{\mathbb{R}}_{\max}^{n} \mid \mathbf{u} \cdot \mathbf{x} = \mathbf{u} \cdot \mathbf{y} \ \forall (\mathbf{x}, \mathbf{y}) \in C\}$.

The (tropical) **segment** between two points $\mathbf{u}$ and $\mathbf{v}$ of $\mathbb{R}_{\max}^{n}$ is $[\mathbf{u}, \mathbf{v}] := \{\lambda.\mathbf{u} \oplus \mu.\mathbf{v} \mid \lambda, \mu \in \mathbb{R}_{\max},\ \lambda \oplus \mu = \mathbb{1}\}$. A subset $V \subset \mathbb{R}_{\max}^{n}$ is a (tropical) **convex** set if $[\mathbf{u}, \mathbf{v}] \subset V$ for all $\mathbf{u}, \mathbf{v} \in V$. It is said to be a **cone** if for all $\mathbf{u} \in V$ and $\lambda \in \mathbb{R}_{\max}$, $\lambda.\mathbf{u} \in V$. Since every scalar $\lambda \in \mathbb{R}_{\max}$ satisfies $\lambda \geq \mathbb{0}$, this definition is analogous to the classical one. Thus, (tropical) convex cones are identical to **subsemimodules** of $\mathbb{R}_{\max}^{n}$.

If V is a convex subset of $\mathbb{R}_{\max}^{n}$, $\mathbf{u} \in M$ is an **extreme point** of V if $\mathbf{u} \in [\mathbf{v}, \mathbf{w}]$ with $\mathbf{v}, \mathbf{w} \in V$ implies $\mathbf{u} = \mathbf{v}$ or $\mathbf{u} = \mathbf{w}$.

If V is a convex cone of $\mathbb{R}_{\max}^{n}$, $\mathbf{u} \in M$ is an **extreme generator** of V, or $\mathbb{R}_{\max}\mathbf{u} := \{\lambda.\mathbf{u} \mid \lambda \in \mathbb{R}_{\max}\}$ is an **extreme ray** of V, if $\mathbf{u} \neq \mathbf{0}$ and if $\mathbf{u} = \mathbf{v} \oplus \mathbf{w}$ with $\mathbf{v}, \mathbf{w} \in V$ imply that $\mathbf{u} = \mathbf{v}$ or $\mathbf{u} = \mathbf{w}$.

Facts:

1. For all $a,\ b \in \overline{\mathbb{R}}_{\max}$, the maximal $c \in \overline{\mathbb{R}}_{\max}$ such that $ac \leq b$, denoted by $a \mathbin{\backslash\!\!\backslash} b$ (or $b \mathbin{/\!\!/} a$), is given by $a \mathbin{\backslash\!\!\backslash} b = b - a$ if $(a, b) \notin \{(-\infty, -\infty), (+\infty, +\infty)\}$, and $a \mathbin{\backslash\!\!\backslash} b = +\infty$ otherwise.
2. [BCOQ92, Eq. 4.82] If $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$ and $B \in \overline{\mathbb{R}}_{\max}^{n \times q}$, then the inequation $AX \leq B$ has

a maximal solution $X \in \overline{\mathbb{R}}_{\max}^{p\times q}$ given by the matrix $A \backslash\!\!\backslash B$ defined by $(A \backslash\!\!\backslash B)_{ij} = \bigwedge_{1\le k\le n} A_{ki} \backslash\!\!\backslash B_{kj}$. Similarly, for $A \in \overline{\mathbb{R}}_{\max}^{n\times p}$ and $C \in \overline{\mathbb{R}}_{\max}^{r\times p}$, the maximal solution $C /\!\!/ A \in \overline{\mathbb{R}}_{\max}^{r\times n}$ of $XA \le C$ exists and is given by $(C /\!\!/ A)_{ij} = \bigwedge_{1\le k\le p} C_{ik} /\!\!/ A_{jk}$.

3. The equation $AX = B$ has a solution if and only if $A(A \backslash\!\!\backslash B) = B$.
4. For $A \in \overline{\mathbb{R}}_{\max}^{n\times p}$, the map $A^\sharp :\ \mathbf{y} \in \overline{\mathbb{R}}_{\min}^{n} \to A \backslash\!\!\backslash \mathbf{y} \in \overline{\mathbb{R}}_{\min}^{p}$ is linear. It is represented by the matrix $-A^T$.
5. [BCOQ92, Table 4.1] For matrices A, B, C with entries in $\overline{\mathbb{R}}_{\max}$ and with appropriate dimensions, we have

$$\begin{aligned} A(A \backslash\!\!\backslash(AB)) = AB, &\quad A \backslash\!\!\backslash(A(A \backslash\!\!\backslash B)) = A \backslash\!\!\backslash B,\\ (A \oplus B) \backslash\!\!\backslash C = (A \backslash\!\!\backslash C) \wedge (B \backslash\!\!\backslash C), &\quad A \backslash\!\!\backslash(B \wedge C) = (A \backslash\!\!\backslash B) \wedge (A \backslash\!\!\backslash C),\\ (AB) \backslash\!\!\backslash C = B \backslash\!\!\backslash(A \backslash\!\!\backslash C), &\quad A \backslash\!\!\backslash(B /\!\!/ C) = (A \backslash\!\!\backslash B) /\!\!/ C. \end{aligned}$$

   The first five identities have dual versions, with $/\!\!/$ instead of $\backslash\!\!\backslash$. Due to the last identity, we shall write $A \backslash\!\!\backslash B /\!\!/ C$ instead of $A \backslash\!\!\backslash(B /\!\!/ C)$.
6. [CGQ97] Let $A \in \overline{\mathbb{R}}_{\max}^{n\times p}$, $B \in \overline{\mathbb{R}}_{\max}^{n\times q}$ and $C \in \overline{\mathbb{R}}_{\max}^{r\times p}$. We have $\operatorname{range} A \subset \operatorname{range} B \iff A = B(B \backslash\!\!\backslash A)$, and $\ker A \subset \ker C \iff C = (C /\!\!/ A)A$.
7. [CGQ96] Let $A \in \overline{\mathbb{R}}_{\max}^{n\times p}$. The map $\Pi_A := A \circ A^\sharp$ is a projector on the range of A, meaning that $(\Pi_A)^2 = \Pi_A$ and $\operatorname{range}\Pi_A = \operatorname{range} A$. Moreover, $\Pi_A(x)$ is the greatest element of the range of A, which is less than or equal to x. Similarly, the map $\Pi^A := A^\sharp \circ A$ is a projector on the range of $A^\sharp$, and $\Pi^A(x)$ is the smallest element of the range of $A^\sharp$ that is greater than or equal to x. Finally, every equivalence class modulo A meets the range of $A^\sharp$ at a unique point.
8. [CGQ04], [DS04] For any $A \in \overline{\mathbb{R}}_{\max}^{n\times p}$, the map $x \mapsto A(-x)$ is a bijection from $\operatorname{range}(A^T)$ to $\operatorname{range}(A)$, with inverse map $x \mapsto A^T(-x)$.
9. [CGQ96], [CGQ97] *Projection onto a range parallel to a kernel.* Let $B \in \overline{\mathbb{R}}_{\max}^{n\times p}$ and $C \in \overline{\mathbb{R}}_{\max}^{q\times n}$. For all $x \in \overline{\mathbb{R}}_{\max}^{n}$, there is a greatest ξ on the range of B such that $C\xi \le Cx$. It is given by $\Pi_B^C(x)$, where $\Pi_B^C := \Pi_B \circ \Pi^C$. We have $(\Pi_B^C)^2 = \Pi_B^C$. Assume now that every equivalence class modulo C meets the range of B at a unique point. This is the case if and only if $\operatorname{range}(CB) = \operatorname{range} C$ and $\ker(CB) = \ker B$. Then $\Pi_B^C(x)$ is the unique element of the range of B, which is equivalent to x modulo C, the map Π_B^C is a linear projector on the range of B, and it is represented by the matrix $(B /\!\!/(CB))C$, which is equal to $B((CB) \backslash\!\!\backslash C)$.
10. [CGQ97] *Regular matrices.* Let $A \in \overline{\mathbb{R}}_{\max}^{n\times p}$. The following assertions are equivalent: (i) there is a linear projector from $\overline{\mathbb{R}}_{\max}^{n}$ to $\operatorname{range} A$; (ii) $A = AXA$ for some $X \in \overline{\mathbb{R}}_{\max}^{p\times n}$; (iii) $A = A(A \backslash\!\!\backslash A /\!\!/ A)A$.
11. [Vor67], [Zim76, Ch. 3] (See also [But94], [AGK05], [DS04].) *Vorobyev–Zimmermann covering theorem.* Assume that $A \in \mathbb{R}_{\max}^{n\times p}$ and $\mathbf{b} \in \overline{\mathbb{R}}_{\max}^{n}$. For $j \in \{1,\dots,p\}$, let

$$S_j = \{i \in \{1,\dots,n\} \mid A_{ij} \ne \mathbb{0} \text{ and } A_{ij} \backslash\!\!\backslash \mathbf{b}_i = (A \backslash\!\!\backslash \mathbf{b})_j\}.$$

   The equation $A\mathbf{x} = \mathbf{b}$ has a solution if and only if $\cup_{1\le j\le p} S_j \supset \operatorname{supp}\mathbf{b}$ or equivalently $\cup_{j\in\operatorname{supp}(A \backslash\!\!\backslash \mathbf{b})} S_j \supset \operatorname{supp}\mathbf{b}$. It has a unique solution if and only if $\cup_{j\in\operatorname{supp}(A \backslash\!\!\backslash \mathbf{b})} S_j \supset \operatorname{supp}\mathbf{b}$ and $\cup_{j\in J} S_j \not\supset \operatorname{supp}\mathbf{b}$ for all strict subsets J of $\operatorname{supp}(A \backslash\!\!\backslash \mathbf{b})$.
12. [Zim77], [SS92], [CGQ04], [CGQS05], [DS04] *Separating a point from a semimodule.* Let $A \in \overline{\mathbb{R}}_{\max}^{n\times p}$ and $\mathbf{b} \in \overline{\mathbb{R}}_{\max}^{n}$. If $\mathbf{b} \notin \operatorname{range} A$, then there exists $\mathbf{c}, \mathbf{d} \in \overline{\mathbb{R}}_{\max}^{n}$ such that the **half-space** $H := \{\mathbf{x} \in \overline{\mathbb{R}}_{\max}^{n} \mid \mathbf{c}\cdot\mathbf{x} \ge \mathbf{d}\cdot\mathbf{x}\}$ contains $\operatorname{range} A$ but not $\mathbf{b}$. We can take $\mathbf{c} = -\mathbf{b}$ and $\mathbf{d} = -\Pi_A(\mathbf{b})$. Moreover, when A and $\mathbf{b}$ have entries in $\mathbb{R}_{\max}$, $\mathbf{c}, \mathbf{d}$ can be chosen with entries in $\mathbb{R}_{\max}$. A refinement of this result (separating two semimodules) appeared in [GS07].

13. [GP97] For any $A \in \overline{\mathbb{R}}_{\max}^{n\times p}$, we have $((\operatorname{range} A)^{\perp})^{\top} = \operatorname{range} A$.
14. [LMS01], [CGQ04] A linear form defined on a finitely generated subsemimodule of $\overline{\mathbb{R}}_{\max}^{n}$ can be extended to $\overline{\mathbb{R}}_{\max}^{n}$. This is a special case of a max-plus analogue of the Riesz representation theorem.
15. [BH84], [GP97] Let $A, B \in \overline{\mathbb{R}}_{\max}^{n\times p}$. The set of solutions $\mathbf{x} \in \overline{\mathbb{R}}_{\max}^{p}$ of $A\mathbf{x} = B\mathbf{x}$ is a finitely generated subsemimodule of $\overline{\mathbb{R}}_{\max}^{p}$. The same is true for the set of solutions of $A\mathbf{x} \leq B\mathbf{x}$.
16. [GP97], [Gau98], [GK11] Let X, Y be finitely generated subsemimodules of $\overline{\mathbb{R}}_{\max}^{n}$, $A \in \overline{\mathbb{R}}_{\max}^{n\times p}$ and $B \in \overline{\mathbb{R}}_{\max}^{r\times n}$. Then $X \cap Y$, $X \oplus Y := \{\mathbf{x} \oplus \mathbf{y} \mid \mathbf{x} \in X,\ \mathbf{y} \in Y\}$, and $X - Y := \{\mathbf{z} \in \overline{\mathbb{R}}_{\max}^{n} \mid \exists \mathbf{x} \in X, \mathbf{y} \in Y,\ \mathbf{x} = \mathbf{y} \oplus \mathbf{z}\}$ are finitely generated subsemimodules of $\overline{\mathbb{R}}_{\max}^{n}$. Also, $A^{-1}(X)$, $B(X)$, and $X^{\perp}$ are finitely generated subsemimodules of $\overline{\mathbb{R}}_{\max}^{p}$, $\overline{\mathbb{R}}_{\max}^{r}$, and $\overline{\mathbb{R}}_{\max}^{n} \times \overline{\mathbb{R}}_{\max}^{n}$, respectively. Similarly, if Z is a finitely generated subsemimodule of $\overline{\mathbb{R}}_{\max}^{n} \times \overline{\mathbb{R}}_{\max}^{n}$, then $Z^{\top}$ is a finitely generated subsemimodule of $\overline{\mathbb{R}}_{\max}^{n}$.
17. Facts 13 to 16 still hold if $\overline{\mathbb{R}}_{\max}$ is replaced by $\mathbb{R}_{\max}$.
18. [GK07] [BSS07] *Minkowski and Carathéodory theorems.* Let V be a convex cone of $\mathbb{R}_{\max}^{n}$, that is closed in the topology induced by the metric

    $$d(\mathbf{u}, \mathbf{v}) = \max_{1 \leq i \leq n} |\exp(\mathbf{u}_i) - \exp(\mathbf{v}_i)|,$$

    which is the case in particular if V is finitely generated. Then, every point of V can be written as a linear combination of at most n extreme generators of V.
19. [GS07], [GM10] *Helly theorem.* If $(V_i)_{1\leq i\leq m}$ is a familly of convex cones of $\mathbb{R}_{\max}^{n}$ the intersection of which is reduced to $\{\mathbf{0}\}$, then there is a subfamily consisting of at most n cones the intersection of which is still reduced to $\{\mathbf{0}\}$. Analogues of other results of discrete convexity (Radon theorem, colorful Carathéodory theorem, and Tverberg theorems) appeared in [GM10].
20. [DS04] *Tropical complex.* If $\mathbf{u}^1, \dots, \mathbf{u}^p$ are vectors in $\mathbb{R}_{\max}^{n}$ with *finite* coordinates, then the semimodule spanned by these vectors is a classical polyhedral complex, which is equivalent to a regular polyhedral subdivision of the product of two simplices. Further information can be found in [DY07, JSY07].
21. [CGQ04] [GK07] *Homogeneization.* If V is a convex subset of $\mathbb{R}_{\max}^{n}$, then $\hat{V} := \{(\mathbf{v}, \lambda\mathbf{v}) \mid \mathbf{v} \in V,\ \lambda \in \mathbb{R}_{\max}\}$ is a convex cone of $\mathbb{R}_{\max}^{n+1}$. Using this correspondence, a number of results concerning convex sets can be deduced from results concerning convex cones, and vice versa. In particular, if V is compact, the extreme points of V are in one to one correspondence with the extreme rays of $\hat{V}$.
22. [AGG12b] Let $A, B \in \mathbb{R}_{\max}^{n\times p}$. The *tropical double description* algorithm allows one to find a minimal set of generators (representatives of extreme rays) of the convex cones $\{\mathbf{x} \in \mathbb{R}_{\max}^{p} \mid A\mathbf{x} = B\mathbf{x}\}$ and $\{x \in \mathbb{R}_{\max}^{p} \mid A\mathbf{x} \leq B\mathbf{x}\}$. This is implemented in the `TPLib` `ocaml` library, `gforge.inria.fr/projects/tplib`.
23. [AGK11] *Tropical McMullen theorem.* Let $A, B \in \mathbb{R}_{\max}^{n\times p}$. The number of extreme rays of the convex cone $\{x \in \mathbb{R}_{\max}^{p} \mid A\mathbf{x} \leq B\mathbf{x}\}$ is bounded from above by $U(n+p, p-1)$, where

    $$U(m,d) := \begin{cases} \binom{m - \lfloor d/2 \rfloor}{\lfloor d/2 \rfloor} + \binom{m - \lfloor d/2 \rfloor - 1}{\lfloor d/2 \rfloor - 1} & \text{for } d \text{ even} \\ 2\binom{m - \lfloor d/2 \rfloor - 1}{\lfloor d/2 \rfloor} & \text{for } d \text{ odd.} \end{cases}$$

    This bound is asymptotically tight for a fixed n as $p \to \infty$; however, the optimal bound is not known.
24. A first algorithm to find one solution of $A\mathbf{x} = B\mathbf{x}$ when $A, B \in \mathbb{R}_{\max}^{n\times p}$, was given in [WB98]. Different algorithms appealing to *cyclic projections*, with various gener-

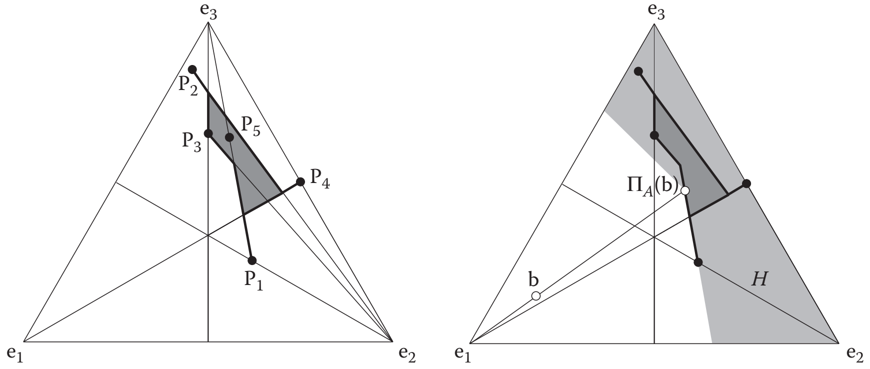


FIGURE 35.1 Projection of a point on a range.

alizations and refinements, were given in [CGB03], [GS07], and [AGNS11]. Finding a vector $\mathbf{x}$ such that $A\mathbf{x} = B\mathbf{x}$ (or $A\mathbf{x} \leq B\mathbf{x}$) is equivalent to solving a mean payoff game [AGG12a], a well-known problem for which a number of algorithms have been developped. In particular, the policy iteration algorithm of [GG98] (see [DG06] for more information) is adapted to large scale instances, although policy iteration can take an exponential time in general [Fri09]. No polynomial time algorithm is known.

Examples:

1. In order to illustrate Fact 11, consider

$$A = \begin{bmatrix} 0 & 0 & 0 & -\infty & 0.5 \\ 1 & -2 & 0 & 0 & 1.5 \\ 0 & 3 & 2 & 0 & 3 \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} 3 \\ 0 \\ 0.5 \end{bmatrix}. \tag{35.3}$$

   Let $\bar{\mathbf{x}} := A \backslash\!\!\backslash \mathbf{b}$. We have $\bar{\mathbf{x}}_1 = \min(-0+3, -1+0, -0+0.5) = -1$, and so, $S_1 = \{2\}$ because the minimum is attained only by the second term. Similarly, $\bar{\mathbf{x}}_2 = -2.5$, $S_2 = \{3\}$, $\bar{\mathbf{x}}_3 = -1.5$, $S_3 = \{3\}$, $\bar{\mathbf{x}}_4 = 0$, $S_4 = \{2\}$, $\bar{\mathbf{x}}_5 = -2.5$, $S_5 = \{3\}$. Since $\cup_{1 \leq j \leq 5} S_j = \{2,3\} \not\supset \operatorname{supp} \mathbf{b} = \{1,2,3\}$, Fact 11 shows that the equation $Ax = \mathbf{b}$ has no solution. This also follows from the fact that $\Pi_A(\mathbf{b}) = A(A \backslash\!\!\backslash \mathbf{b}) = [-1\ 0\ 0.5]^T < \mathbf{b}$.
2. The range of the previous matrix A is represented in Figure 35.1 (left). A nonzero vector $\mathbf{x} \in \mathbb{R}^3_{\max}$ is represented by the point that is the barycenter with weights $(\exp(\beta \mathbf{x}_i))_{1 \leq i \leq 3}$ of the vertices of the simplex, where $\beta > 0$ is a fixed scaling parameter. Every vertex of the simplex represents one basis vector $\mathbf{e}_i$. Proportional vectors are represented by the same point. The i-th column of A, $A_{\cdot i}$, is represented by the point $\mathbf{p}_i$ on the figure. Observe that the broken segment from $\mathbf{p}_1$ to $\mathbf{p}_2$, which represents the semimodule generated by $A_{\cdot 1}$ and $A_{\cdot 2}$, contains $\mathbf{p}_5$. Indeed, $A_{\cdot 5} = 0.5 A_{\cdot 1} \oplus A_{\cdot 2}$. The range of A is represented by the closed region in dark grey and by the bold segments joining the points $\mathbf{p}_1, \mathbf{p}_2, \mathbf{p}_4$ to it.

   We next compute a half-space separating the point b defined in Eq. (35.3) from range A. Recall that $\Pi_A(\mathbf{b}) = [-1\ \ 0\ \ 0.5]^T$. So, by Fact 12, a half-space containing range A and not $\mathbf{b}$ is $H := \{\mathbf{x} \in \overline{\mathbb{R}}^3_{\max} (-3)\mathbf{x}_1 \oplus \mathbf{x}_2 \oplus (-0.5)\mathbf{x}_3 \geq 1\mathbf{x}_1 \oplus \mathbf{x}_2 \oplus (-0.5)\mathbf{x}_3\}$. We also have $H \cap \mathbb{R}^3_{\max} = \{\mathbf{x} \in \mathbb{R}^3_{\max} \mid \mathbf{x}_2 \oplus (-0.5)\mathbf{x}_3 \geq 1\mathbf{x}_1\}$. The set of nonzero points of $H \cap \mathbb{R}^3_{\max}$ is represented by the light gray region in Figure 35.1 (right).

35.7 Max-Plus Linear Independence and Rank

Definitions:

A family $\mathbf{u}^1, \dots, \mathbf{u}^r$ of vectors of $\mathbb{R}^n_{\max}$ is **weakly linearly independent** if for all $i \in \{1, \dots, r\}$, $J \subset \{1, \dots, r\} \setminus \{i\}$ and $\lambda_j \in \mathbb{R}_{\max}$, $j \in J$, we have $\mathbf{u}^i \neq \sum_{j \in J} \lambda_j . \mathbf{u}^j$.

It is **linearly independent in the Gondran–Minoux sense**, or Gondran–Minoux linearly independent, if for all disjoints subsets I and J of $\{1, \dots, r\}$, and all $\lambda_i \in \mathbb{R}_{\max}$, $i \in I \cup J$, we have $\sum_{i \in I} \lambda_i . \mathbf{u}^i \neq \sum_{j \in J} \lambda_j . \mathbf{u}^j$, unless $\lambda_i = \mathbb{0}$ for all $i \in I \cup J$.

It is **tropically linearly independent** if for all series of disjoints subsets I_l, J_l of $\{1, \dots, r\}$, $l = 1, \dots, n$, and all $\lambda_i \in \mathbb{R}_{\max}$, $i \in \{1, \dots, r\}$, such that $\sum_{i \in I_l} \lambda_i . \mathbf{u}^i_l = \sum_{j \in J_l} \lambda_j . \mathbf{u}^j_l$ for all $l = 1, \dots, n$, we have $\lambda_i = \mathbb{0}$ for all $i \in \{1, \dots, r\}$.

For $A \in \mathbb{R}^{n \times n}_{\max}$, we define

$$\det{}^+ A := \sum_{\sigma \in S_n^+} |\sigma|_A, \qquad \det{}^- A := \sum_{\sigma \in S_n^-} |\sigma|_A,$$

where S_n^+ and S_n^- are, respectively, the sets of even and odd permutations of $\{1, \dots, n\}$. The **bideterminant** [GM84] of A is $(\det^+ A, \det^- A)$.

For $A \in \mathbb{R}^{n \times p}_{\max} \setminus \{\mathbf{0}\}$, we define

- The **row rank** (resp. the **column rank**) of A, denoted $\mathrm{r}(A)$ (resp. $\mathrm{c}(A)$), as the number of extreme rays of $\operatorname{range} A^T$ (resp. $\operatorname{range} A$).
- The **factor** rank of A as $\mathrm{f}(A) := \min\{r \geq 1 \mid A = BC, \text{ with } B \in \mathbb{R}^{n \times r}_{\max}, C \in \mathbb{R}^{r \times p}_{\max}\}$. The factor rank is also called **Schein rank**, particularly in the case of Boolean matrices. It is called **Barvinok rank** in [DSS05], since it appeared in the work [BJW98] on the MAXTSP problem.
- The **tropical rank** of A, denoted $\mathrm{trop}(A)$, as the maximal $r \geq 1$ such that there exists an $r \times r$ submatrix B of A for which there is only one permutation σ such that $|\sigma|_B = \operatorname{per} B$.
- The **determinantal rank** of A, denoted $\mathrm{rk}_{\det}(A)$, as the maximal $r \geq 1$ such that A has an $r \times r$ submatrix B such that $\det^+ B \neq \det^- B$.
- The **maximal row rank** of A in the weak, Gondran-Minoux, or tropical sense, denoted, respectively, by $\mathrm{mr}_{\mathrm{w}}(A)$, $\mathrm{mr}_{\mathrm{GM}}(A)$, and $\mathrm{mr}_{\mathrm{t}}(A)$, as the maximal number $r \geq 1$ such that A has r weakly, Gondran-Minoux, or tropically, linearly independent rows, respectively. The maximal column ranks of A are defined similarly, and denoted $\mathrm{mc}_{\mathrm{w}}(A)$, $\mathrm{mc}_{\mathrm{GM}}(A)$, and $\mathrm{mc}_{\mathrm{t}}(A)$.

For $A \in \mathbb{Q}^{n \times p}_{\max}$, the **Kapranov rank** of A, denoted by $\mathrm{Kap}(A)$, is of a different nature. It can be defined [DSS05, Th. 3.3] as the minimal rank of a **lift** of A over the field $\mathbb{C}\{\{t\}\}$ of Puiseux series. Recall that a Puiseux series is a formal sum $f = \sum_{k \geq k_0} a_k t^{k/r}$ where $k_0 \in \mathbb{Z}$, r is a positive integer, and $a_k \in \mathbb{C}$. The valuation $\operatorname{val} f$ is defined as the opposite of the smallest exponent appearing in the expansion of f (e.g., $\operatorname{val}(t^{-1/2} - 3 + t + t^2 + \dots) = 1/2$). A matrix $M \in (\mathbb{C}\{\{t\}\})^{n \times p}$ is said to be a **lift** of A if $\operatorname{val} M_{ij} = A_{ij}$, for all $1 \leq i, j \leq p$.

Facts:

1. [Hel88], [Mol88], [Wag91], [Gau98], [DS04] Let M be a finitely generated subsemimodule of $\mathbb{R}^n_{\max}$. A subset of vectors of M spans M if and only if it contains at least one nonzero element of every extreme ray of M.
2. [GM02] The columns of $A \in \mathbb{R}^{n \times n}_{\max}$ are linearly independent in the Gondran–Minoux sense if and only if $\det^+ A \neq \det^- A$.

3. [RGST05], [AGG09] *Max-plus Cramer's formula, unsigned version.* Let $A \in \mathbb{R}_{\max}^{n\times n}$, and let $\mathbf{b} \in \mathbb{R}_{\max}^{n}$. Define the i-th Cramer's permanent by
$$D_i := \mathrm{per}(A_{\cdot 1} \dots A_{\cdot,i-1}\mathbf{b}A_{\cdot,i+1} \dots A_{\cdot n}),$$
and let $D := \mathrm{per}\, A$. If each of the $n+1$ optimal assignement problems corresponding to $D_1, \dots, D_n$ and D has a unique optimal solution, then there is a unique $\mathbf{x} \in \mathbb{R}_{\max}^{n}$ such that for all $1 \leq i \leq n$, the maximum in $\max(A_{i1}+\mathbf{x}_1, \dots, A_{in}+\mathbf{x}_n, b_i)$ is achieved at least twice. It is characterized by
$$D\mathbf{x}_i = D_i, \qquad \forall 1 \leq i \leq n \ .$$
4. [Plu90], [BCOQ92, Th. 3.78], [AGG09] *Max-plus Cramer's formula, signed version.* Let $A \in \mathbb{R}_{\max}^{n\times n}$, and let $\mathbf{b}^-, \mathbf{b}^+ \in \mathbb{R}_{\max}^{n}$. Define the i-th positive Cramer's determinant by
$$D_i^+ := \det{}^+(A_{\cdot 1} \dots A_{\cdot,i-1}\mathbf{b}^+A_{\cdot,i+1} \dots A_{\cdot n}) \oplus \det{}^-(A_{\cdot 1} \dots A_{\cdot,i-1}\mathbf{b}^-A_{\cdot,i+1} \dots A_{\cdot n}),$$
and the i-th negative Cramer's determinant, D_i^-, by exchanging $\mathbf{b}^+$ and $\mathbf{b}^-$ in the definition of D_i^+. Assume that $\mathbf{x}^+, \mathbf{x}^- \in \mathbb{R}_{\max}^{n}$ have disjoint supports. Then $A\mathbf{x}^+ \oplus \mathbf{b}^- = A\mathbf{x}^- \oplus \mathbf{b}^+$ implies that
$$(\det{}^+ A)\mathbf{x}_i^+ \oplus (\det{}^- A)\mathbf{x}_i^- \oplus D_i^- = (\det{}^- A)\mathbf{x}_i^+ \oplus (\det{}^+ A)\mathbf{x}_i^- \oplus D_i^+ \ \ \forall 1 \leq i \leq n. \qquad (35.4)$$
The converse implication holds, and the vectors $\mathbf{x}^+$ and $\mathbf{x}^-$ are uniquely determined by Eq. (35.4), if $\det^+ A \neq \det^- A$, and if $D_i^+ \neq D_i^-$ or $D_i^+ = D_i^- = \mathbb{0}$, for all $1 \leq i \leq n$. This result is formulated in a simpler way in [Plu90], [BCOQ92], [AGG09] using the *symmetrization* of the max-plus semiring, which leads to more general results. We note that the converse implication relies on the following semiring analogue of the classical adjugate identity: $A \,\mathrm{adj}^+ A \oplus \det^- A\, I = A \,\mathrm{adj}^- A \oplus \det^+ A\, I$, where $\mathrm{adj}^{\pm} A := (\det^{\pm} A(j,i))_{1\leq i,j\leq n}$. This identity, as well as analogues of many other determinantal identities, can be obtained using a general technique of [RS84] which can be formalized as a transfer principle; see [AGG09] where other identities can also be found.
5. [DSS05] The inequality $\mathrm{trop}\, A \leq \mathrm{Kap}(A) \leq \mathrm{f}(A)$ holds for all $A \in \mathbb{Q}_{\max}^{n\times p}$. Moreover, $\mathrm{Kap}(A) = \min(n,p)$ if and only if $\mathrm{trop}(A) = \min(n,p)$. (Note however that the result of [DSS05] is only stated when $A_{ij} \neq \mathbb{0}$, for all i, j.)
6. [IR09], [AGG12a] For $A \in \mathbb{R}_{\max}^{n\times p}$, we have $\mathrm{trop}(A) = \mathrm{mr_t}(A) = \mathrm{mc_t}(A)$. When $A \in \mathbb{Q}_{\max}^{n\times p}$, this result can also be deduced from the equality case in Fact 5.
7. [AGG09] For $A \in \mathbb{R}_{\max}^{n\times p}$, we have
$$\mathrm{trop}(A) \leq \mathrm{rk_{det}}(A) \leq \begin{Bmatrix} \mathrm{mr_{GM}}(A) \\ \mathrm{mc_{GM}}(A) \end{Bmatrix} \leq \mathrm{f}(A) \leq \begin{Bmatrix} \mathrm{r}(A) \\ \mathrm{c}(A) \end{Bmatrix} .$$
Moreover, all these inequalities become equalities if A is regular [CGQ06].
8. [AGG09] We also have $\mathrm{r}(A) \leq \mathrm{mr_w}(A)$, $\mathrm{c}(A) \leq \mathrm{mc_w}(A)$.
9. [KR05] Computing the tropical rank of a matrix is NP-hard. However, the problem of checking whether the tropical rank of a matrix is maximal belongs to NP $\cap$ coNP [AGG12a] (and is therefore unlikely to be NP-hard).
10. [KR06] Computing the Kapranov rank of a matrix is NP-hard.

Examples:

1. The matrix A in Example 35.6.1 has column rank 4: The extreme rays of range A are generated by the first four columns of A. All the other ranks of A are equal to 3.

Generalizations of the Perron–Frobenius theory of nonnegative matrices to linear operators leaving a cone invariant were first developed for operators on a Banach space by Krein and Rutman [KR48], Karlin [Kar59], and Schaefer [Sfr66], although there are early examples in finite dimensions, e.g., [Sch65] and [Bir67]. In this chapter, we describe a generalization that is sometimes called the geometric spectral theory of nonnegative linear operators in finite dimensions, which emerged in the late 1980s. Motivated by a search for geometric analogs of results in the previously developed combinatorial spectral theory of (reducible) nonnegative matrices (for reviews see [Sch86] and [Her99]), this area is a study of the Perron–Frobenius theory of a nonnegative matrix and its generalizations from the cone-theoretic viewpoint. The treatment is linear-algebraic and cone-theoretic (geometric) with the facial and duality concepts and occasionally certain elementary analytic tools playing the dominant role. The theory is particularly rich when the underlying cone is polyhedral (finitely generated) and it reduces to the nonnegative matrix case when the cone is simplicial.

36.1 Perron–Frobenius Theorem for Cones

We work with cones in a real vector space, as "cone" is a real concept. To deal with cones in $\mathbb{C}^n$, we can identify the latter space with $\mathbb{R}^{2n}$. For a discussion on the connection between the real and complex case of the spectral theory, see [TS94, Sect. 8].

Definitions:

A **proper cone** K in a finite-dimensional real vector space V is a closed, pointed, full convex cone, *viz.*

- $K + K \subseteq K$, viz. $\mathbf{x}, \mathbf{y} \in K \Longrightarrow \mathbf{x} + \mathbf{y} \in K$.
- $\mathbb{R}^+ K \subseteq K$, viz. $\mathbf{x} \in K, \alpha \in \mathbb{R}^+ \Longrightarrow \alpha\mathbf{x} \in K$.
- K is closed in the usual topology of V.
- $K \cap (-K) = \{\mathbf{0}\}$, viz. $\mathbf{x}, -\mathbf{x} \in K \Longrightarrow \mathbf{x} = \mathbf{0}$.
- $\text{int}K \neq \emptyset$, where $\text{int}K$ is the interior of K.

Usually, the unqualified term **cone** is defined by the first two items in the above definition. However, in this chapter we call a proper cone simply a **cone**. We denote by K a cone in $\mathbb{R}^n$, $n \geq 2$.

The vector $\mathbf{x} \in \mathbb{R}^n$ is **K-nonnegative**, written $\mathbf{x} \geq^K \mathbf{0}$, if $\mathbf{x} \in K$.

The vector $\mathbf{x}$ is **K-semipositive**, written $\mathbf{x} \gneq^K \mathbf{0}$, if $\mathbf{x} \geq^K \mathbf{0}$ and $\mathbf{x} \neq \mathbf{0}$.

The vector $\mathbf{x}$ is **K-positive**, written $\mathbf{x} >^K \mathbf{0}$, if $\mathbf{x} \in \text{int } K$.

For $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$, we write $\mathbf{x} \geq^K \mathbf{y}$ ($\mathbf{x} \gneq^K \mathbf{y},\ \mathbf{x} >^K \mathbf{y}$) if $\mathbf{x} - \mathbf{y}$ is K-nonnegative (K-semipositive, K-positive).

The matrix $A \in \mathbb{R}^{n\times n}$ is **K-nonnegative**, written $A \geq^K \mathbf{0}$, if $AK \subseteq K$.

The matrix A is **K-semipositive**, written $A \gneq^K \mathbf{0}$, if $A \geq^K \mathbf{0}$ and $A \neq \mathbf{0}$.

The matrix A is **K-positive**, written $A >^K \mathbf{0}$, if $A(K \setminus \{\mathbf{0}\}) \subseteq \text{int } K$.

For $A, B \in \mathbb{R}^{n\times n}$, $A \geq^K B$ ($A \gneq^K B,\ A >^K B$) means $A - B \geq^K \mathbf{0}$ ($A - B \gneq^K \mathbf{0},\ A - B >^K \mathbf{0}$).

A **face** F of a cone $K \subseteq \mathbb{R}^n$ is a subset of K, which is a cone in the linear span of F such that $\mathbf{x} \in F,\ \mathbf{x} \geq^K \mathbf{y} \geq^K \mathbf{0} \Longrightarrow \mathbf{y} \in F$.

(In this chapter, F will always denote a face rather than a field, since the only fields involved are $\mathbb{R}$ and $\mathbb{C}$.) Thus, F satisfies all definitions of a cone except that its interior may be empty.

A face F of K is a **trivial face** if $F = \{\mathbf{0}\}$ or $F = K$.

For a subset S of a cone K, the intersection of all faces of K including S is called the **face of** K **generated by** S and is denoted by $\Phi(S)$. If $S = \{\mathbf{x}\}$, then $\Phi(S)$ is written simply as $\Phi(\mathbf{x})$.

For faces F, G of K, their **meet** and **join** are given, respectively, by $F \wedge G = F \cap G$ and $F \vee G = \Phi(F \cup G)$.

A vector $\mathbf{x} \in K$ is an **extreme vector** if either $\mathbf{x}$ is the zero vector or $\mathbf{x}$ is nonzero and $\Phi(\mathbf{x}) = \{\lambda\mathbf{x} : \lambda \geq 0\}$; in the latter case, the face $\Phi(\mathbf{x})$ is called an **extreme ray**.

If P is K-nonnegative, then a face F of K is a **P-invariant face** if $PF \subseteq F$.

If P is K-nonnegative, then P is **K-irreducible** if the only P-invariant faces are the trivial faces.

If K is a cone in $\mathbb{R}^n$, then a cone, called the **dual cone** of K, is denoted and given by

$$K^* = \{\mathbf{z} \in \mathbb{R}^n : \mathbf{z}^T\mathbf{x} \geq 0 \text{ for all } \mathbf{x} \in K\}.$$

If A is an $n \times n$ complex matrix and $\mathbf{x}$ is a vector in $\mathbb{C}^n$, then the **local spectral radius of** A **at** $\mathbf{x}$ is denoted and given by $\rho_{\mathbf{x}}(A) = \text{lim sup}_{m\to\infty}\|A^m\mathbf{x}\|^{1/m}$, where $\|\cdot\|$ is any norm of $\mathbb{C}^n$. For $A \in \mathbb{C}^{n\times n}$, its spectral radius is denoted by $\rho(A)$ (or ρ) (cf. Section 4.4).

Facts:

Let K be a cone in $\mathbb{R}^n$.

1. The condition int$K \neq \emptyset$ in the definition of a cone is equivalent to $K - K = \mathbb{R}^n$, *viz.*, for all $\mathbf{v} \in \mathbb{R}^n$ there exist $\mathbf{x}, \mathbf{y} \in K$ such that $\mathbf{v} = \mathbf{x} - \mathbf{y}$.
2. A K-positive matrix is K-irreducible.
3. [Van68], [SV70] Let P be a K-nonnegative matrix. The following are equivalent:
   (a) P is K-irreducible.
   (b) $\sum_{i=0}^{n-1} P^i >^K \mathbf{0}$.
   (c) $(I + P)^{n-1} >^K \mathbf{0}$.
   (d) No eigenvector of P (for any eigenvalue) lies on the boundary of K.
4. (Generalization of Perron–Frobenius Theorem) [KR48], [BS75] Let P be a K-irreducible matrix with spectral radius ρ. Then
   (a) ρ is positive and is a simple eigenvalue of P.
   (b) There exists a (up to a scalar multiple) unique K-positive (right) eigenvector $\mathbf{u}$ of P corresponding to ρ.
   (c) $\mathbf{u}$ is the only K-semipositive eigenvector for P (for any eigenvalue).
   (d) $K \cap (\rho I - P)\mathbb{R}^n = \{\mathbf{0}\}$.

5. (Generalization of Perron–Frobenius Theorem) Let P be a K-nonnegative matrix with spectral radius ρ. Then
   (a) ρ is an eigenvalue of P.
   (b) There is a K-semipositive eigenvector of P corresponding to ρ.
6. If P, Q are K-nonnegative and $Q \ {}^{K}\!\!\leq P$, then $\rho(Q) \leq \rho(P)$. Further, if P is K-irreducible and $Q \ {}^{K}\!\!\lneq P$, then $\rho(Q) < \rho(P)$.
7. P is K-nonnegative (K-irreducible) if and only if P^T is K^*-nonnegative (K^*-irreducible).
8. If A is an $n \times n$ complex matrix and $\mathbf{x}$ is a vector in $\mathbf{C}^n$, then the local spectral radius $\rho_{\mathbf{x}}(A)$ of A at $\mathbf{x}$ is equal to the spectral radius of the restriction of A to the A-cyclic subspace generated by $\mathbf{x}$, i.e., $\operatorname{span}\{A^i\mathbf{x} : i = 0, 1, \ldots\}$. If $\mathbf{x}$ is nonzero and $\mathbf{x} = \mathbf{x}_1 + \cdots + \mathbf{x}_k$ is the representation of $\mathbf{x}$ as a sum of generalized eigenvectors of A corresponding, respectively, to distinct eigenvalues $\lambda_1, \ldots, \lambda_k$, then $\rho_{\mathbf{x}}(A)$ is also equal to $\max_{1 \leq i \leq k} |\lambda_i|$.
9. Barker and Schneider [BS75] developed Perron–Frobenius theory in the setting of a (possibly infinite-dimensional) vector space over a fully ordered field without topology. They introduced the concepts of irreducibility and strong irreducibility, and show that these two concepts are equivalent if the underlying cone has ascending chain condition on faces. See [ERS95] for the role of real closed-ordered fields in this theory.

Examples:

1. The nonnegative orthant $(\mathbb{R}_0^+)^n$ in $\mathbb{R}^n$ is a cone. Then $\mathbf{x} \geq^K \mathbf{0}$ if and only if $\mathbf{x} \geq \mathbf{0}$, *viz.* the entries of $\mathbf{x}$ are nonnegative, and F is a face of $(\mathbb{R}_0^+)^n$ if and only if F is of the form F_J for some $J \subseteq \{1, \ldots, n\}$, where
$$F_J = \{\mathbf{x} \in (\mathbb{R}_0^+)^n \ : \ x_i = 0, \ i \notin J\}.$$
Further, $P \geq^K \mathbf{0}$ ($P \gneq^K \mathbf{0}$, $P >^K \mathbf{0}$, P is K-irreducible) if and only if $P \geq \mathbf{0}$ ($P \gneq \mathbf{0}$, $P > \mathbf{0}$, P is irreducible) in the sense used for nonnegative matrices, cf. Chapter 10.
2. The nontrivial faces of the Lorentz (ice cream) cone K_n in $\mathbb{R}^n$, *viz.*
$$K_n = \{\mathbf{x} \in \mathbb{R}^n : (x_1^2 + \cdots + x_{n-1}^2)^{1/2} \leq x_n\},$$
are precisely its extreme rays, each generated by a nonzero boundary vector, that is, one for which the equality holds above. The matrix
$$P = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$
is K_3-irreducible [BP79, p. 22].

36.2 Collatz–Wielandt Sets and Distinguished Eigenvalues

Collatz–Wielandt sets were apparently first introduced and considered in [BS75]. They were so-called later in [TW89] because they are closely related to Wielandt's proof of the Perron–Frobenius theorem for irreducible nonnegative matrices [Wie50], which employs an inequality found in Collatz [Col42]. See also [Sch96] for further remarks on Collatz–Wielandt sets and related max-min and min-max characterizations of the spectral radius of nonnegative matrices and their generalizations.

Definitions:

Let P be a K-nonnegative matrix.

The **Collatz–Wielandt sets** associated with P ([BS75], [TW89], [TS01], [TS03], and [Tam01]) are defined by

$$\begin{aligned}\Omega(P) &= \{\omega \geq 0 : \ \exists \mathbf{x} \in K\backslash\{\mathbf{0}\},\ P\mathbf{x} \geq^K \omega\mathbf{x}\}.\\ \Omega_1(P) &= \{\omega \geq 0 : \ \exists \mathbf{x} \in \text{int } K,\ P\mathbf{x} \geq^K \omega\mathbf{x}\}.\\ \Sigma(P) &= \{\sigma \geq 0 : \ \exists \mathbf{x} \in K\backslash\{\mathbf{0}\},\ P\mathbf{x} \ {}^K\!\!\leq \sigma\mathbf{x}\}.\\ \Sigma_1(P) &= \{\sigma \geq 0 : \ \exists \mathbf{x} \in \text{int } K,\ P\mathbf{x} \ {}^K\!\!\leq \sigma\mathbf{x}\}.\end{aligned}$$

For a K-nonnegative vector $\mathbf{x}$, the **lower and upper Collatz–Wielandt numbers** of $\mathbf{x}$ with respect to P are defined by

$$\begin{aligned}r_P(x) &= \sup\ \{\omega \geq 0 : \ P\mathbf{x} \geq^K \omega\mathbf{x}\},\\ R_P(x) &= \inf\ \{\sigma \geq 0 : \ P\mathbf{x} \ {}^K\!\!\leq \sigma\mathbf{x}\},\end{aligned}$$

where we write $R_P(\mathbf{x}) = \infty$ if no σ exists such that $P\mathbf{x} \ {}^K\!\!\leq \sigma\mathbf{x}$.

A (nonnegative) eigenvalue of P is a **distinguished eigenvalue** for K if it has an associated K-semipositive eigenvector.

The **Perron space** $N_\rho^\nu(P)$ (or N_ρ^ν) is the subspace consisting of all $\mathbf{u} \in \mathbb{R}^n$ such that $(P - \rho I)^k\mathbf{u} = \mathbf{0}$ for some positive integer k. (See Section 6.1 for a more general definition of $N_\lambda^\nu(A)$.)

If F is a P-invariant face of K, then the restriction of P to span$F$ is written as $P|F$. The spectral radius of $P|F$ is written as $\rho[F]$, and if λ is an eigenvalue of $P|F$, its index is written as $\nu_\lambda[F]$.

A cone K in $\mathbb{R}^n$ is **polyhedral** if it is the set of linear combinations with nonnegative coefficients of vectors taken from a finite subset of $\mathbb{R}^n$, and is **simplicial** if the finite subset is linearly independent.

Facts:

Let P be a K-nonnegative matrix.

1. [TW89] A real number λ is a distinguished eigenvalue of P for K if and only if $\lambda = \rho_{\mathbf{b}}(P)$ for some K-semipositive vector $\mathbf{b}$.
2. [Tam90] Consider the following conditions:
   (a) ρ is the only distinguished eigenvalue of P for K.
   (b) $\mathbf{x} \geq^K \mathbf{0}$ and $P\mathbf{x} \ {}^K\!\!\leq \rho\mathbf{x}$ imply that $P\mathbf{x} = \rho\mathbf{x}$.
   (c) The Perron space of P^T contains a K^*-positive vector.
   (d) $\rho \in \Omega_1(P^T)$.

   Conditions (a), (b), and (c) are always equivalent and are implied by condition (d). When K is polyhedral, condition (d) is also an equivalent condition.
3. [Tam90] The following conditions are equivalent:
   (a) $\rho(P)$ is the only distinguished eigenvalue of P for K and the index of $\rho(P)$ is one.
   (b) For any vector $\mathbf{x} \in \mathbb{R}^n$, $P\mathbf{x} \ {}^K\!\!\leq \rho(P)\mathbf{x}$ implies that $P\mathbf{x} = \rho(P)\mathbf{x}$.
   (c) $K \cap (\rho I - P)\mathbb{R}^n = \{\mathbf{0}\}$.
   (d) P^T has a K^*-positive eigenvector (corresponding to $\rho(P)$).
4. [TW89] The following statements all hold:
   (a) [BS75] If P is K-irreducible, then
   $\sup\ \Omega(P) = \sup\ \Omega_1(P) = \inf\ \Sigma(P) = \inf\ \Sigma_1(P) = \rho(P)$.
   (b) $\sup\ \Omega(P) = \inf\ \Sigma_1(P) = \rho(P)$.
   (c) $\inf\ \Sigma(P)$ is equal to the least distinguished eigenvalue of P for K.

(d) sup $\Omega_1(P) = \inf \Sigma(P^T)$ and, hence, is equal to the least distinguished eigenvalue of P^T for K^*.

(e) sup $\Omega(P) \in \Omega(P)$ and inf $\Sigma(P) \in \Sigma(P)$.

(f) When K is polyhedral, we have sup $\Omega_1(P) \in \Omega_1(P)$. For general cones, we may have sup $\Omega_1(P) \notin \Omega_1(P)$.

(g) [Tam90] When K is polyhedral, $\rho(P) \in \Omega_1(P)$ if and only if $\rho(A)$ is the only distinguished eigenvalue of P^T for K^*.

(h) [TS03] $\rho(P) \in \Sigma_1(P)$ if and only if $\Phi((N^1_\rho(P) \cap K) \cup C) = K$, where C is the set $\{\mathbf{x} \in K : \rho_{\mathbf{x}}(P) < \rho(P)\}$ and $N^1_\rho(P)$ is the Perron eigenspace of P.

5. In the irreducible nonnegative matrix case, statement (b) of the preceding fact reduces to the well-known max-min and min-max characterizations of $\rho(P)$ due to Wielandt. Schaefer [Sfr84] generalized the result to irreducible compact operators in L^p-spaces and more recently Friedland [Fri90], [Fri91] also extended the characterizations in the settings of a Banach space or a C^*-algebra.
6. [TW89, Theorem 2.4(i)] For any $\mathbf{x} \geq^K \mathbf{0}, r_P(\mathbf{x}) \leq \rho_{\mathbf{x}}(P) \leq R_P(\mathbf{x})$. (This fact extends the well-known inequality $r_P(\mathbf{x}) \leq \rho(P) \leq R_P(\mathbf{x})$ in the nonnegative matrix case, due to Collatz [Col42] under the assumption that $\mathbf{x}$ is a positive vector and due to Wielandt [Wie50] under the assumption that P is irreducible and $\mathbf{x}$ is semipositive. For similar results concerning a nonnegative linear continuous operator in a Banach space, see [FN89].)
7. A discussion on estimating $\rho(P)$ or $\rho_x(P)$ by a convergent sequence of (lower or upper) Collatz–Wielandt numbers can be found in [TW89, Sect. 5] and [Tam01, Subsect. 3.1.4].
8. [GKT95, Corollary 3.2] If K is strictly convex (i.e., each boundary vector is extreme), then P has at most two distinguished eigenvalues. This fact supports the statement that the spectral theory of nonnegative linear operators depends on the geometry of the underlying cone.

Examples:

1. Consider the cone K in $\mathbb{R}^3$ given by

$$K = \left\{ \lambda \begin{bmatrix} \mathbf{x} \\ 1 \end{bmatrix} \in \mathbb{R}^3 : \mathbf{x} \in C, \lambda \geq 0 \right\} \cup \left\{ \begin{bmatrix} \mathbf{x} \\ 0 \end{bmatrix} \in \mathbb{R}^3 : x \in 0^+C \right\},$$

where C is the closed convex set in $\mathbb{R}^2$ with extreme points $[k(k-1)/2, k]^T, k = 0, 1, 2, \ldots$ and recession cone $0^+C = \{\lambda[1,0]^T : \lambda \geq 0\}$. The matrix $P = J_3(1)$ is K-nonnegative and $\rho(P)(=1)$ is the only distinguished eigenvalue of P for K as well as of P^T for K^*. A little calculation shows that there does not exist a vector $\mathbf{y} \in \text{int}K$ such that $(P - \rho(P)I)\mathbf{y} \in K$. So, in this case, sup$\,\Omega_1(P)$, which is $\rho(P)$ by Fact 4(d), does not belong to $\Omega_1(P)$. This illustrates the second half of Fact 4(f).

This example also shows that in Fact 2, condition (d) is not implied by the equivalent conditions (a)–(c) (by taking P^T for P and K^* for K).

In this example we also have $\rho(P) \notin \Sigma_1(P^T)$ (cf. Fact 4(h)). This is because if there exists $\mathbf{z} \in \text{int}K^*$ such that $\rho(P)z \geq^{K^*} P^T\mathbf{z}$, then since $\rho(P)$ is the only distinguished eigenvalue of P^T for K^*, by Fact 2, $\mathbf{z}$ is an eigenvector of P^T and hence is a multiple of $[0,0,1]^T$, which is a contradiction, as $\langle [0,0,1]^T, [1,0,0]^T \rangle = 0$, $[0,0,1]^T \in \text{int}K^*$ and $[1,0,0]^T \in K$.

36.3 The Peripheral Spectrum, the Core, and the Perron–Schaefer Condition

In addition to using Collatz–Wielandt sets to study Perron–Frobenius theory, we may also approach this theory by considering the core (whose definition will be given below). This geometric approach started with the work of Pullman [Pul71], who succeeded in rederiving the Frobenius theorem for irreducible nonnegative matrices. Naturally, this approach was also taken up in geometric spectral theory. It was found that there are close connections between the core, the peripheral spectrum, the Perron–Schaefer condition, and the distinguished faces of a K-nonnegative linear operator. This led to a revival of interest in the Perron–Schaefer condition and associated conditions for the existence of a cone K such that a preassigned matrix is K-nonnegative. (See [Bir67], [Sfr66], [Van68], [Sch81].) The study has also led to the identification of a necessary and sufficient condition for a collection of Jordan blocks to correspond to the peripheral eigenvalues of a nonnegative matrix. (See [McD03].) The local Perron–Schaefer condition was identified in [TS01] and has played a role in the subsequent work. In the course of this investigation, methods were found for producing invariant cones for a matrix with the Perron–Schaefer condition (see [TS94], [Tam]). These constructions may also be useful in the study of allied fields, such as linear dynamical systems. Invariant cones for matrices are often encountered there. (See, for instance, [BNS89].)

Definitions:

If P is K-nonnegative, then a nonzero P-invariant face F of K is a **distinguished face** (associated with λ) if for every P-invariant face G, with $G \subset F$, we have $\rho[G] < \rho[F]$ (and $\rho[F] = \lambda$).

If λ is an eigenvalue of $A \in \mathbf{C}^{n\times n}$, then $\ker(A - \lambda I)^k$ is denoted by $N_\lambda^k(A)$ for $k = 1, 2, \ldots$, the **index** of λ is denoted by $\nu_A(\lambda)$ (or ν_λ when A is clear), and the **generalized eigenspace** at λ is denoted by $N_\lambda^\nu(A)$. See Section 6.1 for more information.

Let $A \in \mathbb{C}^{n\times n}$.

The **order** of a generalized eigenvector $\mathbf{x}$ for λ is the smallest positive integer k such that $(A - \lambda I)^k\mathbf{x} = \mathbf{0}$. The maximal order of all K-semipositive generalized eigenvectors in $N_\lambda^\nu(A)$ is denoted by ord_λ.

The matrix A satisfies the **Perron–Schaefer condition** [Sfr66], [Sch81] if

- $\rho = \rho(A)$ is an eigenvalue of A.
- If λ is an eigenvalue of A and $|\lambda| = \rho$, then $\nu_A(\lambda) \le \nu_A(\rho)$.

If K is a cone and P is K-nonnegative, then the set $\bigcap_{i=0}^{\infty} P^i K$, denoted by $\mathrm{core}_K(P)$, is called the **core** of P relative to K.

An eigenvalue λ of A is called **a peripheral eigenvalue** if $|\lambda| = \rho(A)$. The peripheral eigenvalues of A constitute the **peripheral spectrum** of A.

Let $\mathbf{x} \in \mathbb{C}^n$. Then A satisfies the **local Perron–Schaefer condition at x** if there is a generalized eigenvector $\mathbf{y}$ of A corresponding to $\rho_{\mathbf{x}}(A)$ that appears as a term in the representation of $\mathbf{x}$ as a sum of generalized eigenvectors of A. Furthermore, the order of $\mathbf{y}$ is equal to the maximum of the orders of the generalized eigenvectors that appear in the representation and correspond to eigenvalues with modulus $\rho_{\mathbf{x}}(A)$.

Facts:

1. [Sfr66, Chap. V] Let K be a cone in $\mathbb{R}^n$ and let P be a K-nonnegative matrix. Then P satisfies the Perron–Schaefer condition.

2. [Sch81] Let K be a cone in $\mathbb{R}^n$ and let P be a K-nonnegative matrix with spectral radius ρ. Then P has at least m linearly independent K-semipositive eigenvectors corresponding to ρ, where m is the number of Jordan blocks in the Jordan form of P of maximal size that correspond to ρ.
3. [Van68] Let $A \in \mathbb{R}^{n\times n}$. Then there exists a cone K in $\mathbb{R}^n$ such that A is K-nonnegative if and only if A satisfies the Perron–Schaefer condition.
4. [TS94] Let $A \in \mathbb{R}^{n\times n}$ that satisfies the Perron–Schaefer condition. Let m be the number of Jordan blocks in the Jordan form of A of maximal size that correspond to $\rho(A)$. Then for each positive integer $k, m \leq k \leq \dim N^1_\rho(A)$, there exists a cone K in $\mathbb{R}^n$ such that A is K-nonnegative and $\dim \operatorname{span}(N^1_\rho(A) \cap K) = k$.
5. Let $A \in \mathbb{R}^{n\times n}$. Let k be a nonnegative integer and let $\omega_k(A)$ consist of all linear combinations with nonnegative coefficients of $A^k, A^{k+1}, \ldots$. The closure of $\omega_k(A)$ is a cone in its linear span if and only if A satisfies the Perron–Schaefer condition. (For this fact in the setting of complex matrices, see [Sch81].)
6. Necessary and sufficient conditions involving $\omega_k(A)$ so that $A \in \mathbb{C}^{n\times n}$ has a positive (nonnegative) eigenvalue appear in [Sch81]. For the corresponding real versions, see [Tam].
7. [Pul71], [TS94] If K is a cone and P is K-nonnegative, then $\operatorname{core}_K(P)$ is a cone in its linear span and $P(\operatorname{core}_K(P)) = \operatorname{core}_K(P)$. Furthermore, $\operatorname{core}_K(P)$ is polyhedral (or simplicial) whenever K is. So when $\operatorname{core}_K(P)$ is polyhedral, P permutes the extreme rays of $\operatorname{core}_K(P)$.
8. For a K-nonnegative matrix P, a characterization of K-irreducibility (as well as K-primitivity) of P in terms of $\operatorname{core}_K(P)$, which extends the corresponding result of Pullman for a nonnegative matrix, can be found in [TS94].
9. [Pul71] If P is an irreducible nonnegative matrix, then the permutation induced by P on the extreme rays of $\operatorname{core}_{(\mathbb{R}_0^+)^n}(P)$ is a single cycle of length equal to the number of distinct peripheral eigenvalues of P. (This fact can be regarded as a geometric characterization of the said quantity (cf. the known combinatorial characterization, see Fact 10.2.5(c)), whereas part (b) of the next fact is its extension.)
10. [TS94, Theorem 3.14] For a K-nonnegative matrix P, if $\operatorname{core}_K(P)$ is a nonzero simplicial cone, then:
    (a) There is a one-to-one correspondence between the set of distinguished faces associated with nonzero eigenvalues and the set of cycles of the permutation τ_P induced by P on the extreme rays of $\operatorname{core}_K(P)$.
    (b) If σ is a cycle of the induced permutation τ_P, then the peripheral eigenvalues of the restriction of P to the linear span of the distinguished P-invariant face F corresponding to σ are simple and are exactly $\rho[F]$ times all the d_σth roots of unity, where d_σ is the length of the cycle σ.
11. [TS94] If P is K-nonnegative and $\operatorname{core}_K(P)$ is nonzero polyhedral, then:
    (a) $\operatorname{core}_K(P)$ consists of all linear combinations with nonnegative coefficients of the distinguished eigenvectors of positive powers of P corresponding to nonzero distinguished eigenvalues.
    (b) $\operatorname{core}_K(P)$ does not contain a generalized eigenvector of any positive powers of P other than eigenvectors.

    This fact indicates that we cannot expect that the index of the spectral radius of a nonnegative linear operator can be determined from a knowledge of its core.
12. A complete description of the core of a nonnegative matrix (relative to the nonnegative orthant) can be found in [TS94, Theorem 4.2].
13. For $A \in \mathbb{R}^{n\times n}$, in order that there exists a cone K in $\mathbb{R}^n$ such that $AK = K$ and A has a K-positive eigenvector, it is necessary and sufficient that A is nonzero,

diagonalizable, all eigenvalues of A are of the same modulus, and $\rho(A)$ is an eigenvalue of A. For further equivalent conditions, see [TS94, Theorem 5.9].

14. [TS94, Theorem 5.4] Let P be a K-nonnegative matrix. If $\operatorname{core}_K(P)$ is a single ray, generated by the unit vector x, then $\lim_{i\to\infty} \dfrac{P^i y}{\|P^i y\|} = x$ for every vector $y \in K \setminus N_0^{\nu}(P)$, where $\|\cdot\|$ is any fixed norm of $\mathbb{R}^n$. The converse holds, if either $\nu_P(\rho(P)) = 1$ or $\operatorname{core}_K(P)$ is polyhedral.
15. For $A \in \mathbb{R}^{n\times n}$, an equivalent condition given in terms of the peripheral eigenvalues of A so that there exists a cone K in $\mathbb{R}^n$ such that A is K-nonnegative and (a) K is polyhedral, or (b) $\operatorname{core}_K(A)$ is polyhedral (simplicial or a single ray) can be found in [TS94, Theorems 7.9, 7.8, 7.12, 7.10].
16. [TS94, Theorem 7.12] Let $A \in \mathbb{R}^{n\times n}$ with $\rho(A) > 0$ that satisfies the Perron–Schaefer condition. Let S denote the multiset of peripheral eigenvalues of A with maximal index (i.e., $\nu_A(\rho)$), the multiplicity of each element being equal to the number of corresponding blocks in the Jordan form of A of order $\nu_A(\rho)$. Let T be the multiset of peripheral eigenvalues of A for which there are corresponding blocks in the Jordan form of A of order less than $\nu_A(\rho)$, the multiplicity of each element being equal to the number of such corresponding blocks. The following conditions are equivalent:
    (a) There exists a cone K in $\mathbb{R}^n$ such that A is K-nonnegative and $\operatorname{core}_K(A)$ is simplicial.
    (b) There exists a multisubset $\widetilde{T}$ of T such that $S \cup \widetilde{T}$ is the multiset union of certain complete sets of roots of unity multiplied by $\rho(A)$.
17. McDonald [McD03] refers to the condition (b) that appears in the preceding result as the *Tam–Schneider condition.* She also provides another condition, called the *extended Tam–Schneider condition*, which is necessary and sufficient for a collection of Jordan blocks to correspond to the peripheral spectrum of a nonnegative matrix.
18. [TS01] If P is K-nonnegative and $\mathbf{x}$ is K-semipositive, then P satisfies the local Perron–Schaefer condition at $\mathbf{x}$.
19. [Tam] Let A be an $n \times n$ real matrix, and let $\mathbf{x}$ be a given nonzero vector of $\mathbb{R}^n$. The following conditions are equivalent:
    (a) A satisfies the local Perron–Schaefer condition at $\mathbf{x}$.
    (b) The restriction of A to $\operatorname{span}\{A^i\mathbf{x} : i = 0, 1, \ldots\}$ satisfies the Perron–Schaefer condition.
    (c) For every (or, for some) nonnegative integer k, the closure of $\omega_k(A, \mathbf{x})$, where $\omega_k(A, \mathbf{x})$ consists of all linear combinations with nonnegative coefficients of $A^k\mathbf{x}$, $A^{k+1}\mathbf{x}, \ldots$, is a cone in its linear span.
    (d) There is a cone C in a subspace of $\mathbb{R}^n$ containing $\mathbf{x}$ such that $AC \subseteq C$.
20. The local Perron–Schaefer condition has played a role in the work of [TS01], [TS03], and [Tam04]. Further work involving this condition and the cones $\omega_k(A, \mathbf{x})$ (defined in the preceding fact) will appear in [Tam06].
21. One may apply results on the core of a nonnegative matrix to rederive simply many known results on the limiting behavior of Markov chains. An illustration can be found in [Tam01, Sect. 4.6].

Examples:

1. For the ice-cream cone $K = \{[\xi_1, \xi_2, \xi_3]^T \in \mathbb{R}^3 : 2\xi_1\xi_3 \geq \xi_2^2, \xi_1, \xi_3 \geq 0\}$, whose axis of

rotation is generated by the vector $[1,0,1]^T$, the matrix

$$A = \begin{bmatrix} 1 & 1 & \frac{1}{2} \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}$$

maps K onto itself; so $\text{core}_K(A) = K$. Clearly, for any nonzero vector $\mathbf{y} \in K$, we have, $\lim_{i\to\infty} \frac{A^i\mathbf{y}}{\|A^i\mathbf{y}\|} = [1,0,0]^T$. This example shows that in the converse part of Fact 14 additional assumptions are needed. Note also that K contains generalized eigenvectors of A of order two or more. So Fact 11(b) is invalid if the polyhedrality assumption on the core is dropped. Now take $\tilde{K} = \{[\xi_1, \xi_2, \xi_3]^T \in (\mathbb{R}_0^+)^3 : 2\xi_1\xi_3 \geq \xi_2^2\}$, i.e., half of an ice-cream cone. Then A is also $\tilde{K}$-nonnegative, but in this case $\text{core}_{\tilde{K}}(A)$ is equal to the single ray generated by the vector $[1,0,0]^T$.

2. Let

$$A = J_2(1) \oplus J_1(1) \oplus J_1(1) \oplus J_2(-1) \oplus J_2(-1) \oplus J_1(-1) \oplus J_2(e^{\frac{2\pi i}{3}}) \oplus J_2(e^{\frac{4\pi i}{3}}) \oplus J_1(i) \oplus J_1(-i).$$

It is clear that A satisfies the Perron–Schaefer condition and the multisets S, T considered in Fact 16 are, respectively, $\{1, -1, -1, e^{\frac{2\pi i}{3}}, e^{\frac{4\pi i}{3}}\}$ and $\{1, 1, -1, i, -i\}$. Take $\tilde{T} = \{1, 1, i, -i\}$. Since the multiset union of S and $\tilde{T}$ is $\mathbf{Z}_2 \cup \mathbf{Z}_3 \cup \mathbf{Z}_4$, where $\mathbf{Z}_m$ denotes the set of all mth roots of unity, by Fact 16 there exists a cone K in $\mathbb{R}^{15}$ such that A is K-nonnegative and $\text{core}_K(A)$ is a simplicial cone.

36.4 Spectral Theory of *K*-Reducible Matrices

In this section, we touch upon the geometric version of the extensive combinatorial spectral theory of reducible nonnegative matrices first found in [Fro12, Sect. 11] and continued in [Sch56]. Many subsequent developments are reviewed in [Sch86] and [Her99]. Results on the geometric spectral theory of reducible K-nonnegative matrices may be largely found in a series of papers by B.S. Tam, some jointly with Wu and H. Schneider [TW89], [Tam90], [TS94], [TS01], [TS03], [Tam04]. For a review containing considerably more information than this section, see [Tam01].

In some studies, the underlying cone is lattice-ordered (for a definition and more information, see [Sfr74]) and, in some studies, the Frobenius form of a reducible nonnegative matrix is generalized; see the work by Jang and Victory [JV93] on positive eventually compact linear operators on Banach lattices. However, in the geometric spectral theory the Frobenius normal form of a nonnegative reducible matrix is not generalized as the underlying cone need not be lattice-ordered. Invariant faces are considered instead of the classes that play an important role in combinatorial spectral theory of nonnegative matrices; in particular, distinguished faces and semidistinguished faces are used in place of distinguished classes and semidistinguished classes, respectively. (For definitions of the preceding terms, see [TS01].)

It turns out that the various results on a reducible nonnegative matrix are extended to a K-nonnegative matrix in different degrees of generality. In particular, the Frobenius–Victory theorem [Fro12], [Vic85] is extended to a K-nonnegative matrix on a general cone. The following are extended to a polyhedral cone: The Rothblum index theorem [Rot75], a characterization (in terms of the accessibility relation between basic classes) for the spectral radius to have geometric multiplicity 1, for the spectral radius to have index 1 [Sch56], and a majorization relation between the (spectral) height characteristic and the (combinatorial) level characteristic of a nonnegative matrix [HS91b]. Various conditions are used to generalize the theorem on equivalent conditions for equality of the two characteristics

[RiS78], [HS89], [HS91a]. Even for polyhedral cones there is no complete generalization for the nonnegative-basis theorem, not to mention the preferred-basis theorem [Rot75], [RiS78], [Sch86], [HS88]. There is a natural conjecture for the latter case [Tam04]. The attempts to carry out the extensions have also led to the identification of important new concepts or tools. For instance, the useful concepts of semidistinguished faces and of spectral pairs of faces associated with a K-nonnegative matrix are introduced in [TS01] in proving the cone version of some of the combinatorial theorems referred to previously. To achieve these ends certain elementary analytic tools are also brought in.

Definitions:

Let P be a K-nonnegative matrix.

A nonzero P-invariant face F is a **semidistinguished face** if F contains in its relative interior a generalized eigenvector of P and if F is not the join of two P-invariant faces that are properly included in F.

A **K-semipositive Jordan chain** for P of length m (corresponding to $\rho(P)$) is a sequence of m K-semipositive vectors $\mathbf{x}, (P-\rho(P)I)\mathbf{x}, \ldots, (P-\rho(P)I)^{m-1}\mathbf{x}$ such that $(P-\rho(P)I)^m\mathbf{x} = \mathbf{0}$.

A basis for $N_\rho^\nu(P)$ is called a **K-semipositive basis** if it consists of K-semipositive vectors.

A basis for $N_\rho^\nu(P)$ is called a **K-semipositive Jordan basis** for P if it is composed of K-semipositive Jordan chains for P.

The set $C(P,K) = \{\mathbf{x} \in K : (P-\rho(P)I)^i\mathbf{x} \in K$ for all positive integers $i\}$ is called the **spectral cone** of P (for K corresponding to $\rho(P)$).

Denote ν_ρ by ν.

The **height characteristic of** P is the ν-tuple $\eta(P) = (\eta_1, ..., \eta_\nu)$ given by:

$$\eta_k = \dim(N_\rho^k(P)) - \dim(N_\rho^{k-1}(P)).$$

The **level characteristic of** P is the ν-tuple $\lambda(P) = (\lambda_1, \ldots, \lambda_\nu)$ given by:

$$\lambda_k = \dim \text{span}(N_\rho^k(P) \cap K) - \dim \text{span}(N_\rho^{k-1}(P) \cap K).$$

The **peak characteristic of** P is the ν-tuple $\xi(P) = (\xi_1, ..., \xi_\nu)$ given by:

$$\xi_k = \dim(P-\rho(P)I)^{k-1}(N_\rho^k \cap K).$$

If $A \in \mathbb{C}^{n\times n}$ and $\mathbf{x}$ is a nonzero vector of $\mathbb{C}^n$, then the **order of x relative to** A, denoted by $\text{ord}_A(\mathbf{x})$, is defined to be the maximum of the orders of the generalized eigenvectors, each corresponding to an eigenvalue of modulus $\rho_{\mathbf{x}}(A)$ that appear in the representation of $\mathbf{x}$ as a sum of generalized eigenvectors of A.

The ordered pair $(\rho_{\mathbf{x}}(A), \text{ord}_A(\mathbf{x}))$ is called the **spectral pair of x relative to** A and is denoted by $\text{sp}_A(\mathbf{x})$. We also set $\text{sp}_A(\mathbf{0}) = (0,0)$ to take care of the zero vector $\mathbf{0}$.

We use $\preceq$ to denote the lexicographic ordering between ordered pairs of real numbers, i.e., $(a,b) \preceq (c,d)$ if either $a < c$, or $a = c$ and $b \leq d$. In case $(a,b) \preceq (c,d)$ but $(a,b) \neq (c,d)$, we write $(a,b) \prec (c,d)$.

Facts:

1. If $A \in \mathbb{C}^{n\times n}$ and $\mathbf{x}$ is a vector of $\mathbb{C}^n$, then $\text{ord}_A(\mathbf{x})$ is equal to the size of the largest Jordan block in the Jordan form of the restriction of A to the A-cyclic subspace generated by $\mathbf{x}$ for a peripheral eigenvalue.

   Let P be a K-nonnegative matrix.
2. In the nonnegative matrix case, the present definition of the level characteristic of P is equivalent to the usual graph-theoretic definition; see [NS94, (3.2)] or [Tam04, Remark 2.2].

3. [TS01] For any $\mathbf{x} \in K$, the smallest P-invariant face containing $\mathbf{x}$ is equal to $\Phi(\hat{\mathbf{x}})$, where $\hat{\mathbf{x}} = (I + P)^{n-1}\mathbf{x}$. Furthermore, $\mathrm{sp}_P(\mathbf{x}) = \mathrm{sp}_P(\hat{\mathbf{x}})$. In the nonnegative matrix case, the said face is also equal to F_J, where F_J is as defined in Example 36.1.1 and J is the union of all classes of P having access to $\mathrm{supp}(\mathbf{x}) = \{i : \mathbf{x}_i > 0\}$. (For definitions of classes and the accessibility relation, see Chapter 10.)
4. [TS01] For any face F of K, P-invariant or not, the value of the spectral pair $\mathrm{sp}_P(\mathbf{x})$ is independent of the choice of $\mathbf{x}$ from the relative interior of F. This common value, denoted by $\mathrm{sp}_A(F)$, is referred to as the **spectral pair of F relative to A**.
5. [TS01] For any faces F, G of K, we have
   (a) $\mathrm{sp}_P(F) = \mathrm{sp}_P(\hat{F})$, where $\hat{F}$ is the smallest P-invariant face of K, including F.
   (b) If $F \subseteq G$, then $\mathrm{sp}_P(F) \preceq \mathrm{sp}_P(G)$. If F, G are P-invariant faces and $F \subset G$, then $\mathrm{sp}_P(F) \preceq \mathrm{sp}_P(G)$; *viz.* either $\rho[F] < \rho[G]$ or $\rho[F] = \rho[G]$ and $\nu_{\rho[F]}[F] \leq \nu_{\rho[G]}[G]$.
6. [TS01] If K is a cone with the property that the dual cone of each of its faces is a facially exposed cone, for instance, when K is a polyhedral cone, a perfect cone, or equals $P(n)$ (see [TS01] for definitions), then for any nonzero P-invariant face G, G is semidistinguished if and only if $\mathrm{sp}_P(F) \prec \mathrm{sp}_P(G)$ for all P-invariant faces F properly included in G.
7. [Tam04] (Cone version of the Frobenius–Victory theorem, [Fro12], [Vic85], [Sch86])

   (a) For any real number λ, λ is a distinguished eigenvalue of P if and only if $\lambda = \rho[F]$ for some distinguished face F of K.
   (b) If F is a distinguished face, then there is (up to multiples) a unique eigenvector $\mathbf{x}$ of P corresponding to $\rho[F]$ that lies in F. Furthermore, $\mathbf{x}$ belongs to the relative interior of F.
   (c) For each distinguished eigenvalue λ of P, the extreme vectors of the cone $N^1_\lambda(P) \cap K$ are precisely all the distinguished eigenvectors of P that lie in the relative interior of certain distinguished faces of K associated with λ.
8. Let P be a nonnegative matrix. The Jordan form of P contains only one Jordan block corresponding to $\rho(P)$ if and only if any two basic classes of P are comparable (with respect to the accessibility relation); all Jordan blocks corresponding to $\rho(P)$ are of size 1 if and only if no two basic classes are comparable [Sch56]. An extension of these results to a K-nonnegative matrix on a class of cones that contains all polyhedral cones can be found in [TS01, Theorems 7.2 and 7.1].
9. [Tam90, Theorem 7.5] If K is polyhedral, then:

   (a) There is a K-semipositive Jordan chain for P of length ν_ρ; thus, there is a K-semipositive vector in $N^\nu_\rho(P)$ of order ν_ρ, *viz.* $\mathrm{ord}_\rho = \nu_\rho$.
   (b) The Perron space $N^\nu_\rho(P)$ has a basis consisting of K-semipositive vectors.

   However, when K is nonpolyhedral, there need not exist a K-semipositive vector in $N^\nu_\rho(P)$ of order ν_ρ, *viz.* $\mathrm{ord}_\rho < \nu_\rho$. For a general distinguished eigenvalue λ, we always have $\mathrm{ord}_\lambda \leq \nu_\lambda$, no matter whether K is polyhedral or not.
10. Part (b) of the preceding fact is not yet a complete cone version of the nonnegative-basis theorem, as the latter theorem guarantees the existence of a basis for the Perron space that consists of semipositive vectors that satisfy certain combinatorial properties. For a conjecture on a cone version of the nonnegative-basis theorem, see [Tam04, Conj. 9.1].
11. [TS01, Theorem 5.1] (Cone version of the (combinatorial) generalization of the Rothblum index theorem, [Rot75], [HS88]).

    Let K be a polyhedral cone. Let λ be a distinguished eigenvalue of P for K. Then there is a chain $F_1 \subset F_2 \subset \ldots \subset F_k$ of $k = \mathrm{ord}_\lambda$ distinct semidistinguished faces of K associated with λ, but there is no such chain with more than ord_λ members. When

K is a general cone, the maximum cardinality of a chain of semidistinguished faces associated with a distinguished eigenvalue λ may be less than, equal to, or greater than ord_λ; see the examples of this section.

12. For $K = (\mathbb{R}_0^+)^n$, *viz.* P is a nonnegative matrix, characterizations of different types of P-invariant faces (in particular, the distinguished and semidistinguished faces) are given in [TS01] (in terms of the concept of an initial subset for P; see [HS88] or [TS01] for definition of an initial subset).
13. [Tam04] The spectral cone $C(P, K)$ is always invariant under $P - \rho(P)I$ and satisfies:
$$N_\rho^1(P) \cap K \subseteq C(A, K) \subseteq N_\rho^\nu(P) \cap K.$$
If K is polyhedral, then $C(A, K)$ is a polyhedral cone in $N_\rho^\nu(P)$.
14. (Generalization of corresponding results on nonnegative matrices, [NS94]) We always have $\xi_k(P) \leq \eta_k(P)$ and $\xi_k(P) \leq \lambda_k(P)$ for $k = 1, \ldots, \nu_\rho$.
15. [Tam04, Theorem 5.9] Consider the following conditions:
    (a) $\eta(P) = \lambda(P)$.
    (b) $\eta(P) = \xi(P)$.
    (c) For each k, $k = 1, \ldots, \nu_\rho$, $N_\rho^k(P)$ contains a K-semipositive basis.
    (d) There exists a K-semipositive Jordan basis for P.
    (e) For each k, $k = 1, \ldots, \nu_\rho$, $N_\rho^k(P)$ has a basis consisting of vectors taken from $N_\rho^k(P) \cap C(P, K)$.
    (f) For each k, $k = 1, \ldots, \nu_\rho$, we have
$$\eta_k(P) = \dim(P - \rho(P)I)^{k-1}[N_\rho^k(P) \cap C(P, K)].$$
Conditions (a) to (c) are equivalent and so are conditions (d) to (f). Moreover, we always have (a)$\Longrightarrow$(d), and when K is polyhedral, conditions (a) to (f) are all equivalent.
16. As shown in [Tam04], the level of a nonzero vector $\mathbf{x} \in N_\rho^\nu(P)$ can be defined to be the smallest positive integer k such that $\mathbf{x} \in \mathrm{span}(N_\rho^k(P) \cap K)$; when there is no such k, the level is taken to be ∞. Then the concepts of K-semipositive level basis, height-level basis, peak vector, etc. can be introduced and further conditions can be added to the list given in the preceding result.
17. [Tam04, Theorem 7.2] If K is polyhedral, then $\lambda(P) \preceq \eta(P)$.
18. Cone-theoretic proofs for the preferred-basis theorem for a nonnegative matrix and for a result about the nonnegativity structure of the principal components of a nonnegative matrix can be found in [Tam04].

Examples:

1. Let K be the cone in $\mathbb{R}^3$ given by:
$$K = \left\{ \lambda \begin{bmatrix} \mathbf{x} \\ 1 \end{bmatrix} \in \mathbb{R}^3 : \mathbf{x} \in C, \lambda \geq 0 \right\} \cup \left\{ \begin{bmatrix} \mathbf{x} \\ 0 \end{bmatrix} \in \mathbb{R}^3 : \mathbf{x} \in 0^+C \right\},$$
where C is the closed convex set in $\mathbb{R}^2$ with extreme points $[k, \alpha^{k-1}]^T$, $k = 1, 2, \ldots$, and recession cone $0^+C = \{\lambda[1, 0]^T : \lambda \geq 0\}$, α being a given real number with $0 < \alpha < 1$. Let
$$P = \begin{bmatrix} 1 & 0 & 1 \\ 0 & \alpha & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$
Then P is K-nonnegative, $\rho(P) = 1$, and $\Phi([1, 0, 0]^T)$ and K are the only nonzero P-invariant faces of K. Since $N_{\rho(P)}^\nu(P) \cap K$ equals the extreme ray $\Phi([1, 0, 0]^T)$, we have

$\mathrm{ord}_{\rho(P)} = 1 < 2 = \nu_P(\rho(P))$, and K is not a semidistinguished face as it does not contain in its interior a generalized eigenvector of P. On the other hand, we have, $\mathrm{sp}_P(K) = (1, 2)$, as $[3, 1 + \alpha, 2]^T (= [1, 1, 1]^T + [2, \alpha, 1]^T)$ belongs to $\mathrm{int}K$ and is the sum of a generalized eigenvector of P of order two for $\rho(P)$ and an eigenvector of P for α. Also, it is clear that $\Phi([1, 0, 0]^T)$ is a semidistinguished face and $\mathrm{sp}_P(\Phi([1, 0, 0]^T)) = (1, 1)$. So K has the property that $\mathrm{sp}_P(K) \succ \mathrm{sp}_P(F)$ for all P-invariant faces F properly included in K, though K is not semidistinguished (cf. Fact 6).

2. Let K and P be as given in Example 36.2.1. Then K has only two nonzero P-invariant faces, namely, $\Phi([1, 0, 0]^T)$ and K itself, both of which are semidistinguished. In this case, every nonzero vector of K is a distinguished generalized eigenvector of P for $\rho(P)$. So $\mathrm{ord}_{\rho(P)}$ and $\nu_P(\rho(P))$ are both equal to 3, but there is no chain of three distinct semidistinguished faces of K associated with $\rho(P)$ (cf. Fact 11).
3. Let K be the cone in $\mathbb{R}^3$ whose intersection with the hyperplane $\{[\xi_1, \xi_2, \xi_3]^T \in \mathbb{R}^3 : \xi_1 + \xi_2 + \xi_3 = 1\}$ is a convex set C lying inside the simplex $\mathrm{conv}\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$, where $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ are the standard unit vectors, and with the relative boundary formed by the line segment joining $\mathbf{e}_1$ and $\mathbf{e}_2$ together with some strictly convex smooth curve. Let $P = J_2(0) \oplus J_1(0)$. Then P is K-nonnegative, and there are precisely three nonzero P-invariant faces of K, namely, $\Phi(\mathbf{e}_1), \Phi(\mathbf{e}_1 + \mathbf{e}_2)$ and K itself. Each of these faces is a semidistinguished face associated with $\rho(P)(= 0)$. So, in this case, the cardinality of a maximum chain of semidistinguished faces associated with $\rho(P)$ is 3, and is greater than $\mathrm{ord}_{\rho(P)}$, which is 2. Note that we also have
$$\mathrm{sp}_P(K) = (0, 2) = \mathrm{sp}_P(\Phi(\mathbf{e}_1 + \mathbf{e}_2)),$$
even though the P-invariant face $\Phi(\mathbf{e}_1 + \mathbf{e}_2)$ is properly included in the semidistinguished face K.

36.5 Linear Equations over Cones

Given a K-nonnegative matrix P and a vector $\mathbf{b} \in K$, in this section we consider the solvability of following two linear equations over cones and some consequences:

$$(\lambda I - P)\mathbf{x} = \mathbf{b}, \;\; \mathbf{x} \in K \tag{36.1}$$

and

$$(P - \lambda I)\mathbf{x} = \mathbf{b}, \;\; \mathbf{x} \in K. \tag{36.2}$$

Equation (36.1) has been treated by several authors in finite-dimensional as well as infinite-dimensional settings, and several equivalent conditions for its solvability have been found. (See [TS03] for a detailed historical account.) The study of Eq. (36.2) is relatively new. A treatment of the equation by graph-theoretic arguments for the special case when $\lambda = \rho(P)$ and $K = (\mathbb{R}_0^+)^n$ can be found in [TW89]. The general case is considered in [TS03]. It turns out that the solvability of Eq. (36.2) is a more delicate problem. It depends on whether λ is greater than, equal to, or less than $\rho_{\mathbf{b}}(P)$.

Facts:

Let P be a K-nonnegative matrix, let $\mathbf{0} \neq \mathbf{b} \in \mathbf{K}$, and let λ be a given positive real number.

1. [TS03, Theorem 3.1] The following conditions are equivalent:

   (a) Equation (36.1) is solvable.

   (b) $\rho_{\mathbf{b}}(P) < \lambda$.
   (c) $\lim\limits_{m\to\infty} \sum\limits_{j=0}^{m} \lambda^{-j} P^j \mathbf{b}$ exists.
   (d) $\lim\limits_{m\to\infty} (\lambda^{-1}P)^m \mathbf{b} = \mathbf{0}$.
   (e) $\langle \mathbf{z}, \mathbf{b} \rangle = 0$ for each generalized eigenvector $\mathbf{z}$ of P^T corresponding to an eigenvalue with modulus greater than or equal to λ.
   (f) $\langle \mathbf{z}, \mathbf{b} \rangle = 0$ for each generalized eigenvector $\mathbf{z}$ of P^T corresponding to a distinguished eigenvalue of P for K that is greater than or equal to λ.

2. For a fixed λ, the set $(\lambda I - P)K \cap K$, which consists of precisely all vectors $\mathbf{b} \in K$ for which Eq. (36.1) has a solution, is equal to $\{\mathbf{b} \in K : \rho_{\mathbf{b}}(P) < \lambda\}$ and is a face of K.
3. For a fixed λ, the set $(P - \lambda I)K \cap K$, which consists of precisely all vectors $\mathbf{b} \in K$ for which Eq. (36.2) has a solution, is, in general, not a face of K.
4. [TS03, Theorem 4.1] When $\lambda > \rho_{\mathbf{b}}(P)$, Eq. (36.2) is solvable if and only if λ is a distinguished eigenvalue of P for K and $\mathbf{b} \in \Phi(N^1_{\lambda}(P) \cap K)$.
5. [TS03, Theorem 4.5] When $\lambda = \rho_{\mathbf{b}}(P)$, if Eq. (36.2) is solvable, then
$$\mathbf{b} \in (P - \rho_{\mathbf{b}}(P)I)\Phi(N^{\nu}_{\rho_{\mathbf{b}}(P)}(P) \cap K).$$
6. [TS03, Theorem 4.19] Let r denote the largest real eigenvalue of P less than $\rho(P)$. (If no such eigenvalues exist, take $r = -\infty$.) Then for any λ, $r < \lambda < \rho(P)$, we have
$$\Phi((P - \lambda I)K \cap K) = \Phi(N^{\nu}_{\rho}(P) \cap K).$$
   Thus, a necessary condition for Eq. (36.2) to have a solution is that $\mathbf{b} \;{}^{K}\!\!\leq \mathbf{u}$ for some $\mathbf{u} \in N^{\nu}_{\rho}(P) \cap K$.
7. [TS03, Theorem 5.11] Consider the following conditions:
   (a) $\rho(P) \in \Sigma_1(P^T)$.
   (b) $N^{\nu}_{\rho}(P) \cap K = N^1_{\rho}(P) \cap K$, and P has no eigenvectors in $\Phi(N^1_{\rho}(P) \cap K)$ corresponding to an eigenvalue other than $\rho(P)$.
   (c) $K \cap (P - \rho(P)I)K = \{\mathbf{0}\}$ (equivalently, $\mathbf{x} \geq^K \mathbf{0}, P\mathbf{x} \geq^K \rho(P)\mathbf{x}$ imply that $P\mathbf{x} = \rho(P)\mathbf{x}$).
   We always have (a)$\Longrightarrow$ (b)$\Longrightarrow$(c). When K is polyhedral, conditions (a), (b), and (c) are equivalent. When K is nonpolyhedral, the missing implications do not hold.

36.6 Elementary Analytic Results

In geometric spectral theory, besides the linear-algebraic method and the cone-theoretic method, certain elementary analytic methods have also been called into play; for example, the use of Jordan form or the components of a matrix. This approach may have begun with the work of Birkhoff [Bir67] and it was followed by Vandergraft [Van68] and Schneider [Sch81]. Friedland and Schneider [FS80] and Rothblum [Rot81] have also studied the asymptotic behavior of the powers of a nonnegative matrix, or their variants, by elementary analytic methods. The papers [TS94] and [TS01] in the series also need a certain kind of analytic argument in their proofs; more specifically, they each make use of the K-nonnegativity of a certain matrix, either itself a component or a matrix defined in terms of the components of a given K-nonnegative matrix (see Facts 3 and 4 in this section). In [HNR90], Hartwig, Neumann, and Rose offer a (linear) algebraic-analytic approach to the Perron–Frobenius theory of a nonnegative matrix, one that utilizes the resolvent expansion, but does not involve the Frobenius normal form. Their approach is further developed by Neumann and Schneider [NS92], [NS93], [NS94]. By employing the concept of spectral cone and combining the cone-theoretic methods developed in the earlier papers of the series with this algebraic-analytic method, Tam [Tam04] offers a unified treatment to reprove or extend (or partly extend) several well-known results in the combinatorial spectral theory of nonnegative matrices. The proofs given in [Tam04] rely on the fact that if K is a cone in $\mathbb{R}^n$, then the set $\pi(K)$ that consists of all K-nonnegative matrices is a cone in the matrix space $\mathbb{R}^{n\times n}$ and if, in addition, K is polyhedral, then so is $\pi(K)$ [Fen53, p. 22], [SV70], [Tam77]. See [Tam01, Sect. 6.5] and [Tam04, Sect. 9] for further remarks on the use of the cone $\pi(K)$ in the study of the spectral properties of K-nonnegative matrices.

In this section, we collect a few elementary analytic results (whose proofs rely on the Jordan form), which have proved to be useful in the study of the geometric spectral theory. In particular, Facts 3, 4, and 5 identify members of $\pi(K)$. As such, they can be regarded as nice results, which are difficult to come by for the following reason: If K is nonsimplicial, then $\pi(K)$ must contain matrices that are not nonnegative linear combinations of its rank-one members [Tam77]. However, not much is known about such matrices [Tam92].

Definitions:

Let P be a K-nonnegative matrix. Denote ν_ρ by ν.

The **principal eigenprojection** of P, denoted by $Z_P^{(0)}$, is the projection of $\mathbb{C}^n$ onto the Perron space N_ρ^ν along the direct sum of other generalized eigenspaces of P.

For $k = 0, \dots, \nu$, the **kth principal component of P** is given by

$$Z_P^{(k)} = (P - \rho(P))^k Z_P^{(0)}.$$

The kth component of P corresponding to an eigenvalue λ is defined in a similar way.

For $k = 0, \dots, \rho$, the **kth transform principal component of P** is given by:

$$J_P^{(k)}(\varepsilon) = Z_P^{(k)} + Z_P^{(k+1)}/\varepsilon + \cdots + Z_P^{(\nu-1)}/\varepsilon^{\nu-k-1} \quad \text{for all } \ \varepsilon \in \mathbb{C}\backslash\{0\}.$$

Facts:

Let P be a K-nonnegative matrix. Denote ν_ρ by ν.

1. [Kar59], [Sch81] $Z_P^{(\nu-1)}$ is K-nonnegative.
2. [TS94, Theorem 7.1(i)] The sum of the $(\nu-1)$th components of P corresponding to its peripheral eigenvalues is K-nonnegative; it is the limit of a convergent subsequence of $((\nu-1)!P^k/[\rho^{k-\nu+1}k^{\nu-1}])$.
3. [Tam04, Theorem 3.6(i)] If K is a polyhedral cone, then for $k = 0, \dots, \nu-1$, $J_P^{(k)}(\varepsilon)$ is K-nonnegative for all sufficiently small positive ε.

36.7 Splitting Theorems and Stability

Splitting theorems for matrices have played a large role in the study of convergence of iterations in numerical linear algebra; see [Var62]. Here we present a cone version of a splitting theorem which is proven in [Sch65] and applied to stability (inertia) theorems for matrices. A closely related result is generalized to operators on a partially ordered Banach space in [DH03] and [Dam04]. There it is used to describe stability properties of (stochastic) control systems and to derive non-local convergence results for Newton's method applied to nonlinear operator equation of Riccati type. We also discuss several kinds of positivity for operators involving a cone that are relevant to the applications mentioned.

For recent splitting theorems involving cones, see [SSA05]. For applications of theorems of the alternative for cones to the stability of matrices, see [CHS97]. Cones occur in many parts of stability theory; see, for instance, [Her98].

Definitions:

Let K be a cone in $\mathbb{R}^n$ and let $A \in \mathbb{R}^{n \times n}$.

A is **positive stable** if $\operatorname{spec}(A) \subseteq \mathbb{C}^+$ *viz.* the spectrum of A is contained in the open right half-plane.

A is **K-inverse nonnegative** if A is nonsingular and A^{-1} is K-nonnegative.

A is **K-resolvent nonnegative** if there exists an $\alpha_0 \in \mathbb{R}$ such that, for all $\alpha > \alpha_0$, $\alpha I - A$ is K-inverse nonnegative.

A is **cross-positive** on K if for all $\mathbf{x} \in K$, $\mathbf{z} \in K^*$, $\mathbf{z}^T\mathbf{x} = 0$ implies $\mathbf{z}^T A\mathbf{x} \geq 0$.

A is a **Z-matrix** if all of its off-diagonal entries are nonpositive.

Facts:

Let K be a cone in $\mathbb{R}^n$.

1. A is K-resolvent nonnegative if and only if A is cross-positive on K. Other equivalent conditions and also Perron–Frobenius type theorems for the class of cross-positive matrices can be found in [Els74], [SV70], or [BNS89].
2. When K is $(\mathbb{R}_0^+)^n$, A is cross-positive on K if and only if $-A$ is a Z-matrix.
3. [Sch65], [Sch97]. Let $T = R - P$ where $R, P \in \mathbb{R}^{n \times n}$ and suppose that P is K-nonnegative. If R satisfies $R(\operatorname{int}K) \supseteq \operatorname{int}K$ or, equivalently, R is K-inverse nonnegative, then the following are equivalent:
   (a) T is K-inverse nonnegative.
   (b) For all $\mathbf{y} >^K \mathbf{0}$ there exists (unique) $\mathbf{x} >^K \mathbf{0}$ such that $\mathbf{y} = T\mathbf{x}$.
   (c) There exists $\mathbf{x} >^K \mathbf{0}$ such that $T\mathbf{x} >^K \mathbf{0}$.
   (d) There exists $\mathbf{x} \geq^K \mathbf{0}$ such that $T\mathbf{x} >^K \mathbf{0}$.
   (e) $\rho(R^{-1}P) < 1$.
4. (A consequence of [GT09, Theorem 6]). Let $T \in \mathbb{R}^{n \times n}$. If $-T$ is K-resolvent nonnegative, then T satisfies $T(\operatorname{int}K) \supseteq \operatorname{int}K$ or $T(\operatorname{int}K) \cap \operatorname{int}K = \emptyset$. But the converse is false; see Example 1 of this section.
5. [DH03, Theorem 2.11], [Dam04, Theorem 3.2.10]. Let T, R, P be as given in Fact 3. If $-R$ is K-resolvent nonnegative, then conditions (a)–(d) of Fact 3 and the following condition (e)$'$ are equivalent:
   (e)$'$ R is K-inverse nonnegative and $\rho(R^{-1}P) < 1$.
   Moreover, the following are additional equivalent conditions:
   (f) T is positive stable.
   (g) R is positive stable and $\rho(R^{-1}P) < 1$.
6. If K is $(\mathbb{R}_0^+)^n$, $R = \alpha I$ and P is a nonnegative matrix, then $T = R - P$ is a Z-matrix. The equivalent conditions considered in Fact 5 are satisfied if and only if T is an M-matrix [BP79, Chap. 6].
7. (Special case of Fact 5 with $P = 0$). Let $T \in \mathbb{R}^{n \times n}$. If $-T$ is K-resolvent nonnegetive, then conditions (a)–(d) of Fact 3 and conditions (f) of Fact 5 are equivalent.
8. [GST04],[SG06],[GT09]. A matrix T is called a **Z**-transformation on K if $-T$ is cross-positive on K. Many properties on M-matrices, such as the **P**-property, **Q**-property (which has connection with the linear complementarity problem), **S**-property, **Z**-property, positive stable property, etc., have been extended. For a **Z**-transformation, the equivalence of these properties is examined for various kinds of cones, particularly for symmetric cones in Euclidean Jordan algebras.
9. [Schn65], [Schn97]. (Special case of Fact 3 with K equal to the cone of positive semidefinite matrices in the real space of $n \times n$ Hermitian matrices, and $R(H) = AHA^*$,

$P(H) = \Sigma_{k=1}^{s} C_k H C_K^*$). Let $A, C_k, k = 1, \ldots, s$ be complex $n \times n$ matrices which can be simultaneously upper triangularized by similarity. Then there exists a natural correspondence $\alpha_i, \gamma_i^{(k)}$ of the eigenvalues of A, C_k, $k = 1, \ldots s$. For Hermitian H, let $T(H) = AHA^* - \Sigma_{k=1}^{s} C_k H C_k^*$. Then the following are equivalent:

(a) $|\alpha_i|^2 - \Sigma_{k=1}^{s} \left|\gamma_i^{(k)}\right|^2 > 0$, $i = 1, \ldots, n$.

(b) For all positive definite G there exists a (unique) positive definite H such that $T(H) = G$.

(c) There exists a positive definite H such that $T(H)$ is positive definite.

10. Gantmacher-Lyapunov [Gan59, Chapter XV] (Special case of Fact 9 with A replaced by $A + I, s = 2, C_1 = A, C_2 = I$, and special case of Fact 7 with K equal to the cone of positive semi-definite matrices in the real space of $n \times n$ Hermitian matrices and $T(H) = AH + HA^*$).
Let $A \in \mathbb{C}^{n \times n}$. The following are equivalent:

    (a) For all positive definite G there exists a (unique) positive definite H such that $AH + HA^* = G$.

    (b) There exists a positive definite H such that $AH + HA^*$ is positive definite.

    (c) A is positive stable.

11. Stein [Ste52](Special case of Fact 9 with $A = I, s = 1, C_1 = C$, and special case of Fact 7 with $T(H) = H - CHC^*$).
Let $C \in \mathbb{C}^{n \times n}$. The following are equivalent:

    (a) There exists a positive definite H such that $H - CHC^*$ is positive definite.

    (b) The spectrum of C is contained in the open unit disk.

Examples:

1. Let $K = (\mathbb{R}_0^+)^2$ and take $T = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$. Then $TK = K$ and so $T(\text{int}K) \supseteq \text{int}K$. Note that $-T$ is not K-resolvent nonnegative as $(\alpha I + T)^{-1}$ is not K-nonnegative for all $\alpha > 1$. This example shows that the converse of Fact 4 is false. Since the eigenvalues of T are -1 and 1, T is not positive stable. Thus, this example also illustrates that we cannot add condition (f) of Fact 5 to the list of equivalent conditions in Fact 3 (taking $P := 0$ and $R := T$).

Spectral sets and K-spectral sets, introduced by John von Neumann in [vNe51], offer a possibility to estimate the norm of functions of matrices in terms of the sup-norm of the function. Examples of such spectral sets include the numerical range or the pseudospectrum of a matrix, discussed in Chapters 23 and 25. Estimating the norm of functions of matrices is an essential task in numerous fields of pure and applied mathematics, such as (numerical) linear algebra [Gre97, Hig08], functional analysis [Pau02], and numerical analysis. More specific examples include probability [DD99], semi-groups and existence results for operator-valued differential equations, the study of numerical schemes for the time discretization of evolution equations [Cro08], or the convergence rate of GMRES (Section 54.7).

The notion of spectral sets involves many deep connections between linear algebra, operator theory, approximation theory, and complex analysis. For example, one requires simple criteria such that the closed unit disk, the numerical range, or another given set in the complex plane is K-spectral for a given matrix A. In order to study sharpness in matrix norm inequalities, one may look for extremal matrices or operators. It is also of interest to consider joint spectral sets of several matrices. How are notions like functional calculus, similarity, or dilation related to spectral sets? Is the intersection of spectral sets also spectral, and what are optimal constants? How is the theory of spectral sets applied to the approximate computation of matrix functions? The aim of this chapter is to give at least partial answers to these questions, and to present a survey of the modern theory of spectral and K-spectral sets for operators and matrices.

37.1 Matrices and Operators

Though many of the examples presented next are for matrices, it is more natural to present the theory of spectral sets in terms of operators acting on an abstract Hilbert space H. Those readers preferring matrices can always think of the Hilbert space $\mathbb{C}^n$ equipped with the usual scalar product.

For the convenience of the reader, some few basic properties of operator theory are collected below. Standard references are the books [RN55, SNF70, Nik02]. All definitions reduce to known ones in the case of matrices.

Definitions:

For a complex Hilbert space H with scalar product $\langle \cdot, \cdot \rangle$ we denote by $\mathcal{L}(H)$ the normed space of all bounded linear operators on H. The **operator norm** of $A \in \mathcal{L}(H)$ is defined by $\|A\| = \sup\{\|Ax\| : \|x\| = 1\}$. A **contraction** is a linear operator whose operator norm is not greater than one, while a **strict contraction** is an operator A such that $\|A\| < 1$. An operator $A \in \mathcal{L}(H)$ is **normal** if A commutes with its Hilbert space adjoint A^*. The operator A is **unitary** if $AA^* = A^*A = I$, where I represents the identity operator. The operator A is **Hermitian**, or **self-adjoint** if $A^* = A$. We say that the operator $A \in \mathcal{L}(H)$ is **positive semidefinite**, and we write $A \succeq 0$, if $\langle Ax, x \rangle \geq 0$ for each $x \in H$.

The **spectrum** $\sigma(A)$ of A is the set of all complex numbers z such that $A - zI$ is not an invertible operator. The **spectral radius** $\rho(A)$ of the operator A is given by $\rho(A) = \sup\{|\lambda| : \lambda \in \sigma(A)\}$. The **numerical range**, or field of values, of an operator A is defined by $W(A) := \{\langle Ax, x \rangle : \|x\| = 1\}$. The **numerical radius** of $A \in \mathcal{L}(H)$ is defined by $w(A) := \sup\{|\lambda| : \lambda \in W(A)\}$. An operator A is a **numerical radius contraction** if $w(A) \leq 1$.

For $s > 0$, we say that the operator $A \in \mathcal{L}(H)$ belongs to the class C_s of Sz.-Nagy and Foias if the inequality $\frac{2-s}{s}\|\zeta Ax\|^2 + 2\frac{s-1}{s}\mathrm{re}(\langle \zeta Ax, x \rangle) \leq \|x\|^2$ holds true for every $x \in H$ and every complex number ζ with $|\zeta| < 1$. The **operator radius** w_s associated with the class C_s may be defined by $w_s(A) = \inf\left\{r : r > 0, \frac{1}{r}A \in C_s\right\}$.

The following notation will be used throughout this chapter: for a set $M \subset \mathbb{C}$ we denote by ∂M its boundary and by $\overline{M}$ its closure. $\mathbb{D}$ is the open unit disk, $\mathbb{T} = \partial\mathbb{D}$ is the unit circle, and X always denotes a closed subset of $\mathbb{C}$.

Definitions:

$\mathcal{R}(X)$ and $\mathcal{C}(X)$ are the sets of complex-valued **bounded rational functions** on X, and complex-valued **bounded continuous functions** on X, respectively, equipped with the **supremum norm** $\|f\|_X = \sup\{|f(x)| : x \in X\}$.

Facts:

The following facts can be found in [SNF66, SNF70].

1. We have $\|A\|/2 \leq w(A) \leq \|A\|$, and $\|A\|/s \leq w_s(A)$. See also Chapter 25.
2. w_s is a norm on $\mathcal{L}(H)$ if and only if $0 < s \leq 2$.
3. $\lim_{s\to\infty} w_s(A) = \rho(A)$ for every $A \in \mathcal{L}(H)$.
4. The class C_1 is the class of all contractions and $w_1(A) = \|A\|$.
5. The class C_2 is the class of all numerical radius contractions and $w_2(A) = w(A)$.

Examples:

1. The space ℓ^2 of complex square summable sequences $x = (x_0, x_1, x_2, \ldots)$ with scalar product $\langle x, y \rangle = \sum_{j=0}^{\infty} x_j \overline{y_j}$ and norm $\|x\| = \sqrt{\langle x, x \rangle}$ is an example of an infinite dimensional Hilbert space. Here the action of a linear operator can be described by the matrix product Ax with an infinite matrix A. The shift operator S acting on ℓ^2 via $S(z_0, z_1, \ldots) = (0, z_0, z_1, \ldots)$ has the norm given by $\|S\| = 1$, the spectrum $\sigma(S) = \overline{\mathbb{D}}$, and the numerical range $W(S) = \mathbb{D}$.
2. We will sometimes also make use of Banach spaces like the space ℓ^p of complex sequences $x = (x_0, x_1, x_2, \ldots)$ with norm $\|x\| = \left(\sum_{j=0}^{\infty} |x_j|^p\right)^{1/p}$ where again the action of bounded linear operators is described by infinite matrices and the matrix-vector product. If one considers the subspaces of sequences where only the first n

entries are non-zero, then there is a canonical isomorphism with $\mathbb{C}^n$, equipped with the vector Hölder p-norm. Similarly, if the infinite matrix A contains non-zero entries only in the first n rows and columns, then the operator norm $\|A\|_{\mathcal{L}(\ell^p)}$ coincides with the matrix Hölder p-norm of the corresponding principal submatrix of order n.

3. Another example of an infinite dimensional Banach space is the set L^p of complex-valued functions defined on some set X, with $\|f\| := \left(\int_X |f(z)|^p \, d\mu(z)\right)^{1/p}$ for a suitable measure μ on X.
4. Since $f \in \mathcal{R}(X)$ is analytic on a neighborhood of X, we get from the maximum principle for analytic functions that

$$\|f\|_X = \sup\{|f(x)| : x \in X\} = \sup\{|f(x)| : x \in \partial X\}.$$

In particular, $\mathcal{R}(X)$ can be seen as a subalgebra of $\mathcal{C}(\partial X)$.

37.2 Basic Properties of Spectral Sets

Let H be a complex Hilbert space and suppose that A is a bounded linear operator on H. Suppose now that $\sigma(A)$ is included in the closed set X and that $f = p/q \in \mathcal{R}(X)$. As the poles of the rational function f are outside of X, the operator $f(A)$ is naturally defined as $f(A) = p(A)q(A)^{-1}$ (see Chapter 17) or, equivalently, by the Riesz holomorphic functional calculus [RN55].

We can now define the central objects of study of this chapter.

Definitions:

Let H be a complex Hilbert space and suppose that $A \in \mathcal{L}(H)$ is a bounded linear operator on H. Let X be a closed set in the complex plane.

For a fixed constant $K > 0$, the set X is said to be a K-**spectral** set for A if the spectrum $\sigma(A)$ of A is included in X and the inequality $\|f(A)\| \leq K\|f\|_X$ holds for every $f \in \mathcal{R}(X)$.

The set X is a **spectral** set for A if it is a K-spectral set with $K = 1$.

Facts:

Facts requiring proof for which no specific reference is given can be found in [RN55, Chap. XI] or [vNe51].

1. Von Neumann inequalities for closed disks of the Riemann sphere:
    (a) a closed disk $\{z \in \mathbb{C} : |z - \alpha| \leq r\}$ is a spectral set for $A \in \mathcal{L}(H)$ if and only if $\|A - \alpha I\| \leq r$.
    (b) the closed set $\{z \in \mathbb{C} : |z - \alpha| \geq r\}$ is spectral for $A \in \mathcal{L}(H)$ if and only if $\|(A - \alpha I)^{-1}\| \leq r^{-1}$.
    (c) the closed right half-plane $\mathbb{C}_0^+ = \{\mathrm{re}(z) \geq 0\}$ is a spectral set for A if and only if $\mathrm{re}(\langle Av, v\rangle) \geq 0$ for all $v \in H$. More generally, any closed half-plane is spectral for A if and only if it contains the numerical range $W(A)$.
2. Suppose that X is a spectral set for A and let $f \in \mathcal{R}(\sigma(A))$. Then $f(X)$ is spectral for $f(A)$. More generally, if $(f_n) \in \mathcal{R}(X)$, $\lim \|f_n - f\|_X = 0$, and $\lim \|f_n(A) - B\| = 0$, then $f(X)$ is a spectral set for B.
3. Any closed superset of a spectral set is again spectral. Any closed superset of a K-spectral set is again K-spectral.
4. The spectrum $\sigma(A)$ of $A \in \mathcal{L}(H)$ is the intersection of all spectral sets for A.

5. [Will67] Any spectral set contains a *minimal spectral set*, i.e., a spectral set having no proper closed subset that is spectral.
6. [vNe51] If the operator $A \in \mathcal{L}(H)$ is normal, then the spectrum $\sigma(A)$ is a (minimal) spectral set for A.
7. [Will67] Let A be a Hilbert space operator, X a set containing $\sigma(A)$, and let z_0 be an interior point of X. If $\|f(A)\| \leq \|f\|_X$ for each rational function $f \in \mathcal{R}(X)$ that vanishes at z_0, then X is a spectral set for A.
8. [Pau02, p. 18] Let A be a Hilbert space operator and let X be a closed set in the complex plane. Let $\mathcal{S} := \mathcal{R}(X) + \overline{\mathcal{R}(X)}$ regarded as a subset of $\mathcal{C}(\partial X)$. If X is spectral for A, then the functional calculus homomorphism from $\mathcal{R}(X)$ to $\mathcal{L}(H)$ defined by $f \mapsto f(A)$ extends to a well defined, *positive map* (i.e., it sends positive functions to positive semidefinite operators) Φ on $\mathcal{S}$, which sends $f + \overline{g}$ to $f(A) + g(A)^*$. Conversely, if Φ is well defined on $\mathcal{S}$, sends $f + \overline{g}$ to $f(A) + g(A)^*$, and is a positive map, then X is spectral for A.
9. Spectral sets and matrices with structure:
   (a) A complex matrix $A \in \mathbb{C}^{n\times n}$ is normal if and only if its set of eigenvalues $\sigma(A)$ is a spectral set for A.
   (b) The unit circle $\mathbb{T}$ is a spectral set for $A \in \mathcal{L}(H)$ if and only if A is unitary.
   (c) The real axis $\mathbb{R}$ is a spectral set for $A \in \mathcal{L}(H)$ if and only if A is self-adjoint (= Hermitian).
   (d) [Will67] Let A be a completely non-normal matrix; that is, the triangular factor in a Schur decomposition of A is not block diagonal. If $\|A\| = 1$, then the closed unit disk is a minimal spectral set.
10. Let $s > 0$. If A belongs to the class C_s, then the closed unit disk is K-spectral for A. [SNF66] We can take $K = 2s - 1$ if $s \geq 1$. [OA75] $K = \max(1, s)$ is the best possible constant.
11. [Nev12] Lemniscates as K-spectral sets: let p be a polynomial with distinct roots and let $A \in \mathcal{L}(H)$. Let $R \geq 0$ satisfy $\|p(A)\| \leq R$ and be such that the lemniscate $\{z \in \mathbb{C} : |p(z)| = R\}$ contains no critical points of p. Then $\{z \in \mathbb{C} : |p(z)| \leq R\}$ is a K-spectral set for A.
12. [KM66] The closed disk $3\overline{\mathbb{D}}$ of radius 3 is spectral for every Banach space contraction: if A is an operator acting on a complex Banach space E such that $\|A\|_{\mathcal{L}(E)} \leq 1$, and p is a polynomial, then $\|p(A)\|_{\mathcal{L}(E)} \leq \sup\{|p(z)| : |z| \leq 3\}$. The constant 3 is the best possible one.

Examples:

1. Suppose that -1 is not in the spectrum of the square matrix A of order n. If the right half-plane $\mathbb{C}_0^+ = \{\mathrm{re}(z) \geq 0\}$ is a spectral set for A, then $\|f(A)\| \leq \|f\|_{\mathbb{C}_0^+} = 1$ for $f(z) = \frac{z-1}{z+1}$ by definition of a spectral set. In order to see that also the converse is true, suppose that $\|f(A)\| \leq 1$. We set $\mathbf{u} = (A + I)\mathbf{v}$, and observe that

$$0 \leq \|\mathbf{u}\|^2 - \|f(A)\mathbf{u}\|^2 = \|(A + I)\mathbf{v}\|^2 - \|(A - I)\mathbf{v}\|^2 = 4\,\mathrm{re}(\langle A\mathbf{v}, \mathbf{v}\rangle).$$

   In particular, $\mathbb{C}_0^+$ contains the spectrum of A, and $\mathbb{C}_0^+$ is spectral for A by Fact 37.2.1c.
2. Let $A \in \mathcal{L}(H)$, and $\alpha, \beta, \gamma, \delta \in \mathbb{C}$, $\alpha\delta - \beta\gamma \neq 0$, $-\delta/\gamma \notin \sigma(A)$. Then both $f(z) = \frac{\alpha z+\beta}{\gamma z+\delta}$ and its inverse are rational functions. Applying twice Fact 37.2.2, we see that X is spectral for A if and only if $f(X)$ is spectral for $f(A)$. Thus, for a proof of Fact 37.2.1 one only needs to show that $\|A\| \leq 1$ implies that $\overline{\mathbb{D}}$ is spectral for A; see, for instance, [RN55, Sect. 153].

3. Let the matrix A be block diagonal with $A = \mathrm{diag}(A_1, A_2)$. Then we have $f(A) = \mathrm{diag}(f(A_1), f(A_2))$ and hence X is K-spectral for A if and only if it is K-spectral for A_1 and A_2.
4. If the matrix A can be factorized as $A = CBC^{-1}$, then $f(A) = Cf(B)C^{-1}$. In particular, if X is K-spectral for B, then it is also K'-spectral for A with $K' \leq K \, \|C\| \, \|C^{-1}\|$.
5. If the matrix A is not diagonalisable, then no finite set X can be K-spectral for A. For a proof, according to Example 37.2.3 and Example 37.2.4 we may suppose that A is a Jordan block of order ≥ 2. Suppose that $X = \{x_1, ..., x_k\}$ is finite. Direct computations show that $f(A) \neq 0$ for $f(x) = (x - x_1) \cdots (x - x_k)$, and hence X cannot be K-spectral for A.

   It follows that the spectrum $\sigma(A)$ of a matrix A is K-spectral if and only if A is diagonalisable, and in this case we can take as K the condition number of the matrix of eigenvectors. See also Example 37.5.4.
6. From Example 37.2.4 we see that a normal, Hermitian, or unitary matrix A has $\sigma(A), \mathbb{R}$, or $\mathbb{T}$, respectively, as a spectral set. Let us show the converse result claimed in Facts 37.2.9a– 37.2.9c.

   If $\mathbb{R}$ is spectral for A, then according to Facts 37.2.2 and 37.2.3 the right half-plane $\mathbb{C}_0^+$ is spectral for iA and for $-iA$, which together with Fact 37.2.1c implies that $\langle A\mathbf{u}, \mathbf{u}\rangle \in \mathbb{R}$ for all $\mathbf{u}$. Hence, A is Hermitian.

   If $\mathbb{T}$ is spectral for A, then $f(\mathbb{T}) = \mathbb{R}$ is spectral for $f(A)$, $f(z) = \frac{1}{i}\frac{z-1}{z+1}$, according to Fact 37.2.2. Hence, $f(A)$ is Hermitian, implying that A is unitary.

   Finally, suppose that $\sigma(A) = \{\lambda_1, ..., \lambda_n\}$ is spectral for A. Then, denoting by $\ell_1, ..., \ell_n$ the Lagrange interpolation polynomials for $\sigma(A)$, that is, ℓ_j a polynomial of degree $\leq n - 1$ with $\ell_j(\lambda_k) = 0$ for $j \neq k$ and $= 1$ for $j = k$, we find that

   $$z = \sum_{j=1}^{n} \lambda_j \ell_j(z) \quad \text{and hence} \quad A = \sum_{j=1}^{n} \lambda_j \ell_j(A).$$

   By Fact 37.2.2, $\ell_j(\sigma(A)) = \{0, 1\} \subset \mathbb{R}$ is spectral for $\ell_j(A)$, implying that $\ell_j(A)$ is Hermitian. From Example 37.2.5 we know that A is diagonalisable, implying that the $\ell_j(A)$ commute, and thus A is normal.
7. The closure X of the ϵ-pseudospectrum of $A \in \mathcal{L}(H)$ is a K-spectral set for $K = \frac{\mathrm{length}(\partial X)}{2\pi\epsilon}$ for any $\epsilon > 0$; see Fact 23.3.5.
8. [BS67, OA75, Cro04a] The disk $\{z \in \mathbb{C} : |z| \leq w(A)\}$ is 2-spectral for A. $K = 2$ is the best possible constant. This follows from Fact 37.2.10.

37.3 Around the von Neumann Inequality

According to Fact 37.2.1a stated for $\alpha = 0$, if A is a Hilbert space contraction and f is a rational function with poles off the closed unit disk, then $\|f(A)\| \leq \|f\|_{\mathbb{D}}$. Since polynomials are dense in the *disk algebra* (that is, the Banach algebra of all complex-valued functions which are analytic on $\mathbb{D}$ and continuous up to $\partial\mathbb{D}$), the previous inequality implies that for every contraction on Hilbert space the rational functional calculus extends to a functional calculus on the disk algebra. The inequality $\|f(A)\| \leq \|f\|_{\mathbb{D}}$ is known in Operator Theory as the *von Neumann inequality.* The aim of this section is to present several variations and generalizations.

Facts:

1. [Foi57] The von Neumann inequality characterizes Hilbert spaces: if E is a complex Banach space such that $\|p(A)\|_{\mathcal{L}(E)} \leq \|p\|_{\overline{\mathbb{D}}}$ holds for every polynomial p and every $A \in \mathcal{L}(E)$ with $\|A\|_{\mathcal{L}(E)} = 1$, then E is isometrically isomorphic to a Hilbert space (i.e., the norm of E comes from an inner product).
2. [Rov82] Another converse of von Neumann inequality: suppose that f_0 is holomorphic on an open subset G of $\mathbb{D}$ and $\|f_0(A)\| \leq 1$ for every contraction A on a Hilbert space, with spectrum contained in G (the operator $f_0(A)$ being defined by the Riesz holomorphic functional calculus). Then f_0 is the restriction to G of a holomorphic function f defined and bounded by 1 on $\mathbb{D}$.
3. [KM66] The von Neumann inequality for arbitrary matrix norms: let p be a polynomial of degree d with complex coefficients and let A be a complex matrix in $\mathbb{C}^{n\times n}$ with $\|A\| \leq 1$ for some subordinate matrix norm $\|\cdot\|$. Then $\|p(A)\| \leq (\pi n + 1)\,\|\,p\,\|_{\overline{\mathbb{D}}}$.
4. The shift as an extremal operator: define the shift S on a suitable space of sequences by $S(z_0, z_1, \ldots) = (0, z_0, z_1, \ldots)$.
    (a) [PPS02, Dix95] An operator-theoretical interpretation of H. Bohr's inequality: let $r > 0$, let E be a Banach space and let $A \in \mathcal{L}(E)$ be such that $\|A\|_{\mathcal{L}(E)} \leq r$. Then $\|p(A)\|_{\mathcal{L}(E)} \leq \|p(rS)\|_{\mathcal{L}(\ell^1)}$ for every polynomial p. We have $\|p(rS)\|_{\mathcal{L}(\ell^1)} \leq \|p\|_{\overline{\mathbb{D}}}$ if and only if $r \leq 1/3$.

    (b) [Pel81, CRW78, Nik02] Matsaev inequality for some classes of contractions: let p be a real number between 1 and ∞. Let $A : L^p \mapsto L^p$ be an isometry on a L^p space. Then A verifies the Matsaev inequality $\|f(A)\|_{\mathcal{L}(L^p)} \leq \|f(S)\|_{\mathcal{L}(\ell^p)}$ for every polynomial f. This inequality also holds for contractions on L^p which preserve positive functions, or for *disjoint contractions* ($A(f)A(g) = 0$ whenever $fg = 0$), or for operators such that $\|A\|_{\mathcal{L}(L^1)} \leq 1$ and $\|A\|_{\mathcal{L}(L^\infty)} \leq 1$.

    (c) [Dru11] Counterexample to a conjecture of Matsaev: let $f(z) = 1 + 2z - \frac{22}{5}z^2$. There is a 2×2 real matrix A with a real (or complex) Hölder 4-norm bounded above by 1 but with the Hölder 4-norm of $f(A)$ exceeding $\|f(S)\|_{\mathcal{L}(\ell^4)}$.
5. Constrained von Neumann inequalities
    (a) [PY80] Let f and g be two polynomials. Suppose that A is a Hilbert space contraction with spectrum included in $\mathbb{D}$ such that $g(A) = 0$. Then $\|f(A)\| \leq \|f(S^* \mid \ker g(S^*))\|$, where S^* is the backward shift,

    $$S^*(z_0, z_1, z_2, \ldots) = (z_1, z_2, \ldots),$$

    which is the adjoint of S acting on ℓ^2.

    (b) [HdlH92] Let A be a Hilbert space nilpotent contraction with $A^n = 0$, $n \geq 2$. Then

    $$w(A) \leq w(S^* \mid \ker(S^{n*}))) = \cos\frac{\pi}{n+1}.$$

    (c) [BC02] Let $n \geq 2$. Let $A \in \mathcal{L}(H)$ be a contraction such that $A^n = 0$. Then for each $s > 0$ and each polynomial f, we have $w_s(f(A)) \leq w_s(f(S_n^*))$. Here S_n^* denotes the nilpotent Jordan block

    $$S_n^* = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \ddots & \vdots \\ \vdots & & \ddots & \ddots & 0 \\ \vdots & & & \ddots & 1 \\ 0 & \cdots & \cdots & \cdots & 0 \end{bmatrix}$$

which is unitarily equivalent to $S^* \mid \mathbb{C}^n = S^* \mid \ker S^{n*}$. In particular, for any m we have

$$w(A^m) \leq \cos \frac{\pi}{k(m,n)+2}, \quad k(m,n) := [\frac{n-1}{m}].$$

Also, if the degree of the polynomial f is at most $n-1$, then

$$w_s(f(A)) \leq \left(\frac{2}{s}-1\right) \|f\|_{\mathbb{D}}^{s} \left[\inf_{\theta \in \mathbb{R}} \sup\{|f(\zeta)| : \zeta \in \mathbb{C}, \zeta^{2n-1} = e^{i\theta}\}\right]^{1-s}$$

if $s \in (0,1]$, and

$$w_s(f(A)) \leq \|f\|_{\mathbb{D}}^{2-s} \left[\inf_{\theta \in \mathbb{R}} \sup\{|f(\zeta)| : \zeta \in \mathbb{C}, \zeta^{2n-1} = e^{i\theta}\}\right]^{s-1}$$

if $s \in [1,2]$.

(d) [BC02] Let $A \in \mathcal{L}(H)$ be a nilpotent Hilbert space operator satisfying

$$I - A^*A \succeq 0, \quad I - 2A^*A + A^{*2}A^2 \succeq 0,$$

and $A^n = 0$, $n \geq 2$. Then

$$w_s(f(A)) \leq w_s(f(B_n^*))$$

for all $s > 0$ and all polynomials f. Here B_n^* is given by the matrix

$$B_n^* = \begin{bmatrix} 0 & \sqrt{\frac{1}{2}} & 0 & \cdots & 0 \\ 0 & 0 & \sqrt{\frac{2}{3}} & \ddots & \vdots \\ \vdots & & \ddots & \ddots & 0 \\ \vdots & & & \ddots & \sqrt{\frac{n}{n+1}} \\ 0 & \cdots & \cdots & \cdots & 0 \end{bmatrix}$$

which is unitarily equivalent to a compression of the Bergman shift.

(e) [BC02] Suppose $A \in \mathcal{L}(H)$ satisfies $\|A\| \leq 1$, $A^3 = 0$ and $I - 2A^*A + A^{*2}A^2 \succeq 0$. Then

$$w(A) \leq \sqrt{\frac{7}{24}} \quad \text{and} \quad w(A^2) \leq \sqrt{\frac{1}{12}}$$

and these constants are the best possible ones.

(f) [BC02] The link between the extremal operator in the constrained von Neumann inequalities and the Taylor coefficients of rational functions positive on the unit circle $\mathbb{T}$: let $F = P/Q$ be a rational function with no principal part and which is positive on the unit circle. Then the kth Taylor coefficient c_k satisfies $|c_k| \leq c_0 w(R^k)$, where $R = S^* \mid \ker(Q(S^*))$. In particular, if $P(e^{it}) = \sum_{j=-n+1}^{n-1} c_j e^{ijt}$ is a positive trigonometric polynomial, $n \geq 2$, then $|c_k| \leq c_0 \cos(\frac{\pi}{[\frac{n-1}{k}]+2})$ for $1 \leq k \leq n-1$ and, for every distinct numbers k and l among $\{0, \ldots, n-1\}$, there exists $\gamma \in \mathbb{R}$ such that $|c_k| + |c_l| \leq c_0 w(S_n^k + e^{i\gamma} S_n^l)$. We also have

$$|c_k| + |c_l| \leq c_0 \left(1 + \cos \frac{\pi}{[\frac{n-1}{k+l}] + 2}\right)^{1/2} \left(1 + \cos \frac{\pi}{[\frac{n-1}{|k-l|}] + 2}\right)^{1/2}.$$

Examples:

1. [RN55, p. 436] The von Neumann inequality fails for the Hölder 1-norm in $\mathbb{C}^2$ (or in ℓ^1): consider

$$A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad f(z) = \frac{z+a}{1+\overline{a}z}, \quad a = \frac{i}{2}, \quad f(A) = \begin{bmatrix} 4i/5 & 3/5 \\ 3/5 & 4i/5 \end{bmatrix},$$

then $\|A\|_1 = 1$, $\|f\|_{\overline{\mathbb{D}}} = 1$, but $\|f(A)\|_1 = \frac{7}{5} > 1$.

2. [Pau02, p. 23] The Schwarz-Pick lemma as a consequence of von Neumann inequality: Let p be a polynomial such that $\|p\|_{\overline{\mathbb{D}}} < 1$. Let a, b, and c be complex numbers such that $|a| < 1, |c| < 1$, $a \neq c$, and $|b|^2 = (1-|a|^2)(1-|c|^2)$. Consider the 2×2 matrix

$$A = \begin{bmatrix} a & b \\ 0 & c \end{bmatrix}$$

acting on the Euclidean space $\mathbb{C}^2$. Then $\|A\| = 1$,

$$p(A) = \begin{bmatrix} p(a) & b\frac{p(a)-p(c)}{a-c} \\ 0 & p(c) \end{bmatrix}$$

and the von Neumann inequality $\|p(A)\| \leq \|p\|_{\overline{\mathbb{D}}}$ implies that

$$\left| \frac{p(a)-p(c)}{a-c} \right|^2 \leq \frac{1-|p(a)|^2}{1-|a|^2} \frac{1-|p(c)|^2}{1-|c|^2}.$$

Using the identity $|1-u\overline{v}|^2 = (1-|u|^2)(1-|v|^2) + |u-v|^2$, this can be written as

$$\left| \frac{p(a)-p(c)}{1-\overline{p(c)}p(a)} \right| \leq \left| \frac{a-c}{1-\overline{c}a} \right|.$$

37.4 The Multidimensional von Neumann Inequality

Definitions:

We say that the **multidimensional von Neumann inequality** holds for a fixed n-tuple of commuting operators $A = (A_1, A_2, \ldots, A_n)$ if

$$\|p(A_1, \ldots, A_n)\| \leq \|p\|_{\overline{\mathbb{D}}^n}$$

for every polynomial p in n (commutative) variables.

Facts:

We use [Nik02] as a general reference.

1. The multidimensional von Neumann inequality holds in the following situations:
   (a) [And63] For a pair of commutative Hilbert space contractions ($n = 2$).
   (b) For a commutative family of isometries.
   (c) For a family of *doubly commuting* (i.e., $A_iA_j = A_jA_i$ for all i and j and $A_i^*A_j = A_jA_i^*$ whenever $i \neq j$) contractions.
   (d) [Bre61] For a commutative family A such that $\sum_{j=1}^{n} \|A_j\|^2 \leq 1$.

2. [AM05] Distinguished varieties: let A_1 and A_2 be two commuting contractive matrices, neither of which has eigenvalues of modulus one. Then there is a polynomial $q \in \mathbb{C}[z,w]$ such that the algebraic set $V = \{(z,w) \in \mathbb{D}^2 : q(z,w) = 0\}$ verifies $\|p(A_1, A_2)\| \leq \|p\|_V$ for any polynomial p in two variables and $\overline{V} \cap \partial(\mathbb{D}^2) = \overline{V} \cap (\partial\mathbb{D})^2$ (the variety exits the bidisk through the distinguished boundary).
3. Extremal n-tuples.
   (a) [Dru78, Pop99, Arv98] The Drury-Arveson space and the von Neumann inequality of Drury-Popescu-Arveson: let $\mathbb{B}^n = \{z \in \mathbb{C}^n : \sum_{j=1}^n |z_j|^2 < 1\}$ be the unit open ball in $\mathbb{C}^n$. Let DA_n be the Drury-Arveson space of all power series g such that
   $$g = \sum_{\alpha \geq 0} a_\alpha z^\alpha, \quad \|g\|_{DA_n}^2 = \sum_{\alpha \geq 0} |a_\alpha|^2 \frac{\alpha!}{|\alpha|!} < \infty,$$
   where $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{N}^n$, $|\alpha| = \sum_{j=1}^n \alpha_j$ and $\alpha! = \prod_{j=1}^n (\alpha_j!)$. The Drury-Arveson space DA_n can be also regarded as the reproducing kernel Hilbert space with kernel
   $$k_\lambda(z) = \frac{1}{1 - \sum_{j=1}^n z_j \overline{\lambda_j}}, \quad z, \lambda \in \mathbb{B}^n.$$
   Let $S_j g(z) = z_j g(z)$, where $z = (z_1, \ldots, z_n)$ and $g \in DA_n$. Let $A = (A_1, \ldots, A_n)$ be a commutative n-tuple on a Hilbert space H such that $I \succeq \sum_{j=1}^n A_j A_j^*$, or equivalently,
   $$\left\| \sum_{j=1}^n A_j x_j \right\|^2 \leq \sum_{j=1}^n \|x_j\|^2$$
   for all $x_j \in H$. Then
   $$\|p(A_1, \ldots, A_n)\| \leq \|p(S_1, \ldots, S_n)\|$$
   for every polynomial p.
   (b) [Dru78] A dual version: let S_j^*, $j = 1, \ldots, n$, be the backward shift operators on the Cauchy dual DA_n^* of the Drury-Arveson space. This means that $g = \sum_{\alpha \geq 0} a_\alpha z^\alpha$ with $\|g\|_{DA_n^*}^2 = \sum_{\alpha \geq 0} |a_\alpha|^2 \frac{|\alpha|!}{\alpha!} < \infty$, and $a_\alpha(S_j^* g) = a_{\alpha+\delta_j}(g)$ for all $\alpha \geq 0$, where $\delta_j = (\delta_{jk})_{1 \leq k \leq n}$. Let $A = (A_1, \ldots, A_n)$ be a commutative n-tuple on a Hilbert space H such that $I \succeq \sum_{j=1}^n A_j^* A_j$, or equivalently,
   $$\sum_{j=1}^n \|A_j x\|^2 \leq \|x\|^2$$
   for all $x \in H$. Then
   $$\|p(A_1, \ldots, A_n)\| \leq \|p(S_1^*, \ldots, S_n^*)\|$$
   for every polynomial p.
4. [Mla71] Mlak's von Neumann inequality with operator coefficients: let $C_k : H \mapsto H$ be bounded linear operators, $k = 0, \ldots, n$, and $A \in \mathcal{L}(H)$ be a contraction which double-commutes with the C_k's, i.e., $AC_k = C_k A$ and $AC_k^* = C_k^* A$ for every k. Then
$$\left\| \sum_{j=0}^n C_j A^j \right\| \leq \sup_{|z| \leq 1} \left\| \sum_{j=0}^n C_j z^j \right\|.$$

5. [Lub78] Let $(A_1, \dots, A_n)$ be commuting contractions on a Hilbert space H. Then the polydisk $\{(z_1, \dots, z_n) : |z_i| < \sqrt{n}, 1 \leq j \leq n\}$ is a spectral set for $(A_1, \dots, A_n)$.
6. [Hir72] The *Poisson radius*: let $A = (A_1, \dots, A_n)$ be an n-tuple of commuting operators on a Hilbert space H, with spectra included in $\overline{\mathbb{D}}$. Define

$$P_j(rA_j, \zeta_j) = \operatorname{re}\big(\big((\zeta_j I + rA_j)(\zeta_j I - rA_j)^{-1}\big)\big)$$

for $0 \leq r < 1$, $\zeta_j \in \mathbb{T}$, $1 \leq j \leq n$, and the Poisson radius $r_P(A)$ of A as the supremum of $r \in [0,1)$ such that

$$\frac{1}{n!} \sum_{\sigma} P_{\sigma(1)}(rA_{\sigma(1)}, \zeta_{\sigma(1)}) \dots P_{\sigma(n)}(rA_{\sigma(n)}, \zeta_{\sigma(n)})$$

is a positive operator for every $\zeta \in \mathbb{T}^n$, where σ runs over all permutations of $(1, \dots, n)$. Then $0 < r_P(A) \leq 1$ and $\|f(r_P(A)A)\| \leq \|f\|_{\overline{\mathbb{D}}^n}$ for every polynomial f.
7. [Agl90] The Schur-Agler class: let f be an analytic function of n complex variables $\lambda = (\lambda^1, \cdots, \lambda^n)$. Then $f(rA_1, \dots, rA_n)$ has norm at most 1 for any $r < 1$ and any collection of n commuting contractions $(A_1, \dots, A_n)$ on a Hilbert space if and only if there are auxiliary Hilbert spaces H_j, $1 \leq j \leq n$, and an isometry $V \in \mathcal{L}(\mathbb{C} \oplus H_1 \oplus \cdots \oplus H_n)$ such that, if $H = H_1 \oplus \cdots \oplus H_n$, V is written with respect to $\mathbb{C} \oplus H$ as $V = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$, and $\mathcal{E}_\lambda = \lambda^1 I_{H_1} \oplus \cdots \lambda^n I_{H_n}$, then $f(\lambda) = A + B\mathcal{E}_\lambda (I_H - D\mathcal{E}_\lambda)^{-1} C$.
8. [Boz89] Bożejko's von Neumann inequality for non-commuting tuples: let A_k, $1 \leq k \leq n$, be (not necessarily commuting) contractions on H. Let $f = f(x_1, \dots, x_n)$ be a polynomial in the noncommutative indeterminates $x_1, \dots, x_n$. Then

$$\|f(A_1, \dots, A_n)\| \leq \sup\{\|f(U_1, \dots, U_n)\| : U_j \text{ unitary matrices on } \mathbb{C}^{m \times m}, m \in \mathbb{N}\}.$$

Open Problems:

1. [Dix76] It is not known if for each n there exists a finite constant C_n such that for any commuting contractions $A_1, \dots, A_n$ and any polynomial f in n variables one has

$$\|f(A_1, \dots, A_n)\| \leq C_n \|f\|_{\overline{\mathbb{D}}^n}.$$

It is generally believed that such a constant C_n does not exist. One knows that C_n must increase faster than any power of n.

Examples:

1. [Var74] The multidimensional von Neumann inequality fails in general for $n \geq 3$ and matrices $A_1, \dots, A_n \in \mathbb{C}^{d \times d}$.
2. [Var74] The multidimensional von Neumann inequality can fail with $n = 3$ and $d = 5$. The three matrices $A_1, A_2, A_3 \in \mathbb{C}^{5 \times 5}$ are commuting contractions (with respect to the Euclidean norm), and the polynomial $p(z_1, z_2, z_3) = z_1^2 + z_2^2 + z_3^2 - 2z_1z_2 - 2z_1z_3 - 2z_2z_3$ satisfies $\|p\|_{\mathbb{T}^3} = 5$ and $\|f(A_1, A_2, A_3)\| > 5$:

$$A_1 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{3}} & 0 \end{bmatrix}, \quad A_2 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & -\frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{3}} & 0 \end{bmatrix},$$

$$A_3 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & -\frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} & 0 \end{bmatrix}.$$

3. [CD75] Denote by $\mathbf{e}_j$, $1 \leq j \leq 8$, the vectors of the standard orthonormal basis of $\mathbb{C}^8$. Let $p(z_1, z_2, z_3) = z_1 z_2 z_3 - z_1^3 - z_2^3 - z_3^3$. There exist three commuting matrices $A_k \in \mathbb{C}^{8\times 8}$, $k = 1, 2, 3$, such that $\|A_i\| \leq 1$ and $\|p(A_1, A_2, A_3)\| \geq 4 > \|p\|_{\mathbb{T}^3}$. The contractions A_i are acting on the orthonormal basis as follows:

$$\begin{aligned} A_1 &: \mathbf{e}_1 \longrightarrow \mathbf{e}_2 \longrightarrow (-\mathbf{e}_5) \longrightarrow (-\mathbf{e}_8) \longrightarrow 0, \mathbf{e}_3 \longrightarrow \mathbf{e}_7 \longrightarrow 0, \mathbf{e}_4 \longrightarrow \mathbf{e}_6 \longrightarrow 0 \\ A_2 &: \mathbf{e}_1 \longrightarrow \mathbf{e}_3 \longrightarrow (-\mathbf{e}_6) \longrightarrow (-\mathbf{e}_8) \longrightarrow 0, \mathbf{e}_2 \longrightarrow \mathbf{e}_7 \longrightarrow 0, \mathbf{e}_4 \longrightarrow \mathbf{e}_5 \longrightarrow 0 \\ A_3 &: \mathbf{e}_1 \longrightarrow \mathbf{e}_4 \longrightarrow (-\mathbf{e}_7) \longrightarrow (-\mathbf{e}_8) \longrightarrow 0, \mathbf{e}_2 \longrightarrow \mathbf{e}_6 \longrightarrow 0, \mathbf{e}_3 \longrightarrow \mathbf{e}_5 \longrightarrow 0 \end{aligned}$$

4. [Var74] Given $K > 0$, there exist a positive integer n, commuting operators $A_1, \ldots, A_n$, and a polynomial p such that $\sum_{j=1}^{n} \|A_j\|^2 \leq 1$ and

$$\|p(A_1, \ldots, A_n)\| > K \sup \left\{ |p(z_1, \ldots, z_n)| : \sum_{j=1}^{n} |z_j|^2 \leq 1 \right\}.$$

37.5 Dilations, Complete Bounds, and Similarity Problems

Definitions:

For a given closed set X of the complex plane, we say that $A \in \mathcal{L}(H)$ has a **normal ∂X-dilation** if there exist a Hilbert space $\mathcal{H}$ containing H and a normal operator N on $\mathcal{H}$ with $\sigma(N) \subset \partial X$ so that

$$f(A) = P_H f(N) \mid_H$$

for every rational function f with poles off X. Here P_H is the orthogonal projection of $\mathcal{H}$ onto H.

If $X = \overline{\mathbb{D}}$, then N is a unitary operator and we say that A has a **unitary (strong) dilation**. Notice that in this chapter, contrary to Chapter 25, a unitary (strong) dilation A is a common dilation of all powers of A.

For a fixed $s > 0$, we say that $A \in \mathcal{L}(H)$ has an **s-unitary dilation** if there exists a Hilbert space $\mathcal{H}$ containing H and a unitary operator U on $\mathcal{H}$ such that

$$A^n = s P_H U^n \mid_H, \quad (n \geq 1).$$

The last two definitions agree in the case $s = 1$.

We denote by $M_n(\mathcal{R}(X))$ the algebra of n by n matrices with entries from $\mathcal{R}(X)$.

Considering the (spectral) Hölder 2-norm for matrices in $\mathbb{C}^{n\times n}$, we can endow $M_n(\mathcal{R}(X))$ with the norm

$$\| \left(f_{ij}\right)_{1\leq i,j\leq n} \|_X = \sup\{\| \left(f_{ij}(x)\right)_{1\leq i,j\leq n} \| : x \in X\} = \sup\{\| \left(f_{ij}(x)\right)_{1\leq i,j\leq n} \| : x \in \partial X\}.$$

In a similar fashion we endow $M_n(\mathcal{L}(H))$ with the norm it inherits by regarding an element $(A_{ij})_{1\leq i,j\leq n}$ in $M_n(\mathcal{L}(H))$ as an operator acting on the direct sum of n copies of H.

For a fixed constant $K > 0$, the set X is said to be a **complete** K**-spectral** set for A if $\sigma(A) \subset X$ and the inequality $\|(f_{ij}(A))_{1\le i,j\le n}\| \le K\|(f_{ij})_{1\le i,j\le n}\|_X$ holds for every matrix $(f_{ij}) \in M_n(\mathcal{R}(X))$ and every n.

A **complete spectral** set is a complete K-spectral set with $K = 1$.

We also say that A is **power bounded** if $\sup_n \|A^n\| < \infty$.

Two Hilbert space operators A and B are said to be **similar** if there exists an invertible operator L such that $B = L^{-1}AL$.

Facts:

All the following facts except those with a specific reference can be found in [SNF70, Pie01, Pau02]. We denote by A a Hilbert space operator and by X a closed subset of $\mathbb{C}$.

1. [Arv69, Arv72, Pau84b] A has a normal ∂X-dilation if and only if X is a complete spectral set for A.
2. X is completely K-spectral for A if and only if X is completely spectral for an operator $B \in \mathcal{L}(H)$ similar to A, say, $B = L^{-1}AL$, with $\|L^{-1}\|\,\|L\| \le K$.
3. Each completely spectral set for A is spectral. Conversely, a spectral set for A is completely spectral in the following situations:
   (a) If X is a closed disk.
   (b) [Agl85] If X is an annulus.
   (c) [Pau02, Theorem 4.4] If $\mathbb{C}\backslash X$ has only finitely many components and the interior of X is simply connected or, more generally, if $\mathcal{R}(X) + \overline{\mathcal{R}(X)}$ is dense in $\mathcal{C}(\partial X)$.
   (d) [AHR08, DMC05] There is a closed set X in $\mathbb{C}$ having "two holes" and an operator A such that X is spectral for A but not completely spectral. [Pic10] More generally, such a counterexample exists whenever X is a symmetric domain in $\mathbb{C}$ with n holes, $2 \le n < \infty$.
   (e) [DP86, Pau02] Let the boundary of the compact $X \subset \mathbb{C}$ consist of $n+1$ disjoint Jordan curves. If X is a spectral set, then it is a complete $(2n+1)$-spectral set.
4. Each completely K-spectral set for $A \in \mathcal{L}(H)$ is K-spectral. [Pau87] The converse is true whenever A is a 2×2 matrix. [Pie97] However, there exists an example where $\overline{\mathbb{D}}$ is K-spectral for $A \in \mathcal{L}(H)$ but not completely K'-spectral for any K'.
5. A combination of these facts yields several corollaries which historically came first:
   (a) (Sz.-Nagy dilation theorem) Every Hilbert space contraction has a unitary dilation.
   (b) (Berger dilation theorem) Every numerical radius contraction has a unitary 2-dilation.
   (c) (Paulsen criterion) An operator A is similar to a contraction if and only if it has the closed unit disk as a complete K-spectral set.
6. Operators of class C_s:
   (a) [SNF66, OA75] Let $s > 0$. Every operator of class C_s has a unitary s-dilation.
   (b) Let $s > 0$. If A is of class C_s, then $\|f(A)\| \le \max\{|s\cdot f(z) + (1-s)\cdot f(0)| : |z| \le 1\}$ for every polynomial f.
   (c) Let H be a complex Hilbert space of dimension ≥ 2. Then the class C_s increases with s: we have $\mathrm{C}_s \subset \mathrm{C}_{s'}$ and $\mathrm{C}_s \ne \mathrm{C}_{s'}$ for $0 < s < s'$. The set of operators acting on H which belong to one of the classes C_s, for some $s > 0$, is dense in the strong operator topology in the set of all power bounded operators.

7. Unitary dilations for n-tuples:
   (a) [And63] Every pair of commuting contractions on a Hilbert space has a pair of commuting unitary dilations.
   (b) [GR69] Every n-tuple $A = (A_1, \dots, A_n) \in \mathcal{L}(H)^n$ which is *cyclic commutative*, i.e.,
   $$A_1 A_2 \dots A_n = A_n A_1 \dots A_{n-1} = \dots = A_2 A_3 \dots A_n A_1,$$
   has a cyclic commutative dilation to an n-tuple of unitaries.
   (c) [Ope06] Let G be an *acyclic* graph on n vertices $\{1, 2, \dots, n\}$ (this means that it does not contain a cycle as a subgraph). Let $A = (A_1, A_2, \dots, A_n)$ be an n-tuple of contractions on a Hilbert space that *commute according to* G, that is $A_i A_j = A_j A_i$ whenever (i, j) is an edge of G. Then there exists an n-tuple U of unitaries on a larger Hilbert space that commute according to G such that U dilates A. This property may fail if G contains a cycle.
8. Power boundedness and similarity to a contraction (i.e., $\overline{\mathbb{D}}$ is completely K-spectral):
   (a) [Rot60, Her76, Voi74] Rota type theorems: If $A \in \mathcal{L}(H)$ with $\sigma(A) \subset \mathbb{D}$, then A is similar to a contraction. More general results are true for some closed sets $X \subset \mathbb{C}$ and for operators A with $\sigma(A) \subset X$.
   (b) [Bad03] A Banach space Rota theorem and Matsaev inequality: Let E_1 be a Banach space and suppose that $A \in \mathcal{L}(E_1)$ has $\sigma(A) \subset \mathbb{D}$. Then, for every $p > 1$, there exists a Banach space E_2 which is a quotient of the set $\ell^p(E_1)$ of E_1-valued sequences and an isomorphism $L : E_2 \to E_1$ such that, if $B = L^{-1}AL \in \mathcal{L}(E_2)$, then
   $$\|f(B)\|_{\mathcal{L}(E_2)} \leq \|f(S)\|_{\mathcal{L}(\ell^p(E_1))}$$
   for each polynomial f and, even more generally,
   $$\|(f_{ij}(B))_{1\leq i,j\leq n}\|_{\mathcal{L}(E_2^n)} \leq \|(f_{ij}(S))_{1\leq i,j\leq n}\|_{\mathcal{L}(\ell^p(E_1)^n)}$$
   for all matrices of polynomials.
   (c) If A is compact and power bounded, then A is similar to a contraction.
   (d) [Fog64, Leb68, Pie97] There is a Hilbert space operator A which is power bounded but for which the closed unit disk is not K-spectral for any K, and thus A is not similar to a contraction. There is a Hilbert space operator A which is not similar to a contraction but for which the closed unit disk is K-spectral for A, for some K.
   (e) [Pel82, Bou86] Let $A \in \mathcal{L}(H)$ with $M = \sup_n \|A^n\| < \infty$ and let p be a polynomial of degree $d \geq 2$. Then $\|p(A)\| \leq M^2 (\log d) \, \| p \|_{\overline{\mathbb{D}}}$. A similar result holds for norms of matrices of polynomials, and the $\log d$ term in the inequality is the best one may hope for.
   (f) [Bou86] Bourgain's estimate for matrices similar to contractions: If A is a matrix such that, with the (spectral) Hölder 2-norm, $\|f(A)\| \leq C\|f\|_{\overline{\mathbb{D}}}$ for any polynomial f, then there is an invertible matrix L such that $\|L^{-1}AL\| \leq 1$ and $\|L^{-1}\| \, \|L\| \leq KC^4 \log(n+1)$, where K is a numerical constant independent of n.
   (g) [BePr98] Suppose that $\overline{\mathbb{D}}$ is K-spectral for $A \in \mathcal{L}(H)$. Then there exist Hilbert spaces H_1, H_2, contractions $A_1 \in \mathcal{L}(H_1)$, $A_2 \in \mathcal{L}(H_2)$ and injective linear operators $X_1 : H_1 \mapsto H, X_2 : H \mapsto H_2$ with dense ranges such that $X_1 A_1 = AX_1$ and $A_2 X_2 = X_2 A$. See also Example 37.5.5.

Open Problems:

1. [SNF70] What is the obstruction to an n-tuple of commuting Hilbert space contractions having commuting unitary dilation?

Examples:

1. The (unilateral) backward shift operator $S^* \in \mathcal{L}(\ell^2)$ defined by $(S^*x)_j = x_{j+1}$, $j \in \mathbb{N}$, is easily seen to be a contraction, with spectrum $\sigma(S^*) = \overline{\mathbb{D}}$. Hence, $X = \overline{\mathbb{D}}$ is a (completely) spectral set for S^*. For quadratic summable sequences x indexed by $\mathbb{Z}$, one defines the bilateral backward shift operator B through $(Bx)_j = x_{j+1}$, $j \in \mathbb{Z}$, which is clearly unitary. Since $(B^n x)_j = x_{j+n}$, $j \in \mathbb{Z}$, $n \geq 1$, we see that B is a 1-unitary dilation and thus a unitary dilation of S^*.
2. The notion of (weak or strong) unitary dilation is a nice illustration of why it is important in linear algebra sometimes to have recourse to infinite dimensions: we say that $A \in \mathbb{C}^{n\times n}$ is imbedded in $B \in \mathbb{C}^{m\times m}$ if $B = \begin{bmatrix} A & * \\ * & * \end{bmatrix}$. Given a contraction $A \in \mathbb{C}^{n\times n}$, is there a unitary $B \in \mathbb{C}^{m\times m}$ such that $p(A)$ is imbedded in $p(B)$ for any polynomial p of degree at most k? This property, related with the exactness property for Krylov spaces, reduces to (strong) unitary dilations for $k = \infty$ considered above, and for $k = 1$ to the (weak) unitary dilation considered in Section 25.6. The latter problem has the solution [Hal50]

$$B = \begin{bmatrix} A & (I - AA^*)^{1/2} \\ (I - A^*A)^{1/2} & -A^* \end{bmatrix}.$$

   Egérvary [Ege54] showed that such an imbedding is always possible with $m = (k+1)n$: for example, one may imbed the n-dimensional shift in a unitary circulant of order $m = (k+1)n$. It is also known that in general such an imbedding for finite m is impossible for $k = \infty$; see also [LS13, MS13] for more modern aspects of this question.
3. [Par70] Let U and V be two contractions in $\mathcal{L}(H)$ such that U is unitary and $UV \neq VU$. We define three commuting contractions in $\mathcal{L}(H \oplus H)$ by defining

$$A_1 = \begin{bmatrix} 0 & 0 \\ I & 0 \end{bmatrix}, A_2 = \begin{bmatrix} 0 & 0 \\ U & 0 \end{bmatrix}, A_3 = \begin{bmatrix} 0 & 0 \\ V & 0 \end{bmatrix}.$$

   Then the commuting triplet $A = (A_1, A_2, A_3)$ verifies the multidimensional von Neumann inequality but does not possess a commuting triplet of (strong) unitary dilations.
4. Let $A \in \mathbb{C}^{n\times n}$ be diagonalizable. Then A is power bounded if and only if $\sigma(A) \subset \overline{\mathbb{D}}$, and in this case A is similar to the contraction given by the Jordan canonical form. Here $\overline{\mathbb{D}}$ is (completely) K-spectral, with K the condition number of the matrix of eigenvectors.

   If $A \in \mathbb{C}^{n\times n}$ is not diagonalizable, then $\sigma(A) \subset \mathbb{D}$ still implies (through, e.g., the Cauchy integral formula and the pseudo-spectrum) that $\overline{\mathbb{D}}$ is completely K-spectral for some K. However, in general, the Jordan canonical form is no longer a contraction.
5. [MT07] Let $T \in \mathcal{L}(H)$ and $S \in \mathcal{L}(K)$ be Hilbert space operators. We say that T is a *quasiaffine transform* of S if there exists an injective operator $A : H \mapsto K$ with dense range such that $AT = SA$. We say that T is *quasisimilar* to S if each operator is a quasiaffine transform of the other.

   There exists a power bounded operator on a Hilbert space which is not quasisimilar to a contraction.

6. [Pie97, DP97, Bad03, BP01, Ric02] Let $\alpha = (\alpha_0, \alpha_1, \dots)$ be a sequence in ℓ^2 and set
$$R(\alpha) = \begin{bmatrix} S^* & Y(\alpha) \\ 0 & S \end{bmatrix} \in \mathcal{L}(\ell^2(H) \oplus \ell^2(H)),$$
where S is the shift on the Hilbert space $\ell^2(H)$ of H-valued square summable sequences, H is of infinite dimension, and $Y(\alpha) = \Big[\alpha_{i+j} C_{i+j}\Big]_{i,j\geq 0}$, where the C_j's are operators verifying the *canonical anticommutation relations* $C_iC_j + C_jC_i = 0$ and $C_iC_j^* + C_j^*C_i = \delta_{ij}I$.
Then the operator $R(\alpha)$ is polynomially bounded if and only if $\sup_{k\geq 0}(k+1)^2 \sum_{i\geq k} |\alpha_i|^2$ is finite, and $R(\alpha)$ is similar to a contraction if and only if $\sum_{k\geq 0}(k+1)^2|\alpha_k|^2$ is finite.

37.6 Intersections of Spectral and K-Spectral Sets

In this part we will discuss intersections of spectral sets, including the annulus problem of Shields [Shi74]. It is known that the intersection of two spectral sets is not necessarily a spectral set, see [Will67, Mis84, Pau02] and Example 37.6.1. However, the same question for K-spectral sets remains open, although the previous examples indicate that one may not use the same constant. We refer to [Pau88] and the book [Pau02] for modern surveys of known properties of K-spectral and complete K-spectral sets.

Facts:

1. [DP86, Pau02] If two K-spectral sets have disjoint boundaries, then their intersection is a K'-spectral set for some K'.
2. [Sta86] The intersection of a simply connected spectral set X of $A \in \mathcal{L}(H)$ whose interior has finitely many components with the closure a simply connected open set G containing the spectrum of A is a K'-spectral set for A for some K'. Weaker versions of this statement concerning the connectivity of X and/or G have been given in [Sta90, Lew90].
3. [Lew90] The intersection of a (complete) K-spectral set for a bounded linear operator A with the closure of any open set containing the spectrum of A is a (complete) K'-spectral set for A for some K'.
4. [BBC09] Let $A \in \mathcal{L}(H)$, and consider the intersection $X = D_1 \cap D_2 \cap \cdots \cap D_n$ of n disks of the Riemann sphere $\overline{\mathbb{C}}$, each of them being spectral for A. Then X is a complete K-spectral set for A, with a constant $K \leq n + n(n-1)/\sqrt{3}$.
   (a) [Cro07] If in this result we add the requirement that the disks D_j and thus X are convex, then X is a complete 11.08-spectral set for A.
   (b) For $n = 2$ we obtain the constant $K = 2 + 2/\sqrt{3}$ for various configurations as shown in Figure 37.1, in particular for a strip/sector obtained by the intersection of two half-planes and discussed in Example 37.7.3a, or the lens-shaped intersection of two disks [BC06].
5. [Shi74] For $R > 1$, consider the annulus $X = X(R) = \{z \in \mathbb{C} : R^{-1} \leq |z| \leq R\}$, and denote by $K(R)$ (and by $K_{cb}(R) \geq K(R)$, respectively), the smallest constant K such that X is a K-spectral set (and a complete K-spectral set, respectively) for any invertible $A \in \mathcal{L}(H)$ verifying $\|A\| \leq R$ and $\|A^{-1}\| \leq R$. Then
   (a) [Shi74] $K(R) \leq 2 + \sqrt{\frac{R^2+1}{R^2-1}}$;
   (b) [BBC09] $K_{cb}(R) \leq 2 + \frac{R+1}{\sqrt{R^2+R+1}} \leq 2 + \frac{2}{\sqrt{3}}$. The first upper bound is sharper than Fact 37.6.5a for $R \leq 3.1528$;

(c) [BBC09] $K(R) \geq \frac{4}{3}$.

(d) [BBC09] $K_{cb}(R) \leq \max\{3, 2 + \sum_{n=1}^{\infty} \frac{4}{R^{2n}+1}\}$, being sharper than Fact 37.6.5a for $R \geq 1.8544$, and sharper than Fact 37.6.5b whenever $R \geq 1.9879$. It follows in particular that $K(R) \leq 3$ for $R \geq 2.0953$.

(e) [Cro12a] $K_{cb}(R) \leq 2+\frac{1}{\pi}\int_0^{\pi} \left|\frac{R^2+\exp(i\theta)}{R^2-\exp(i\theta)}\right| d\theta$, being always sharper than Fact 37.6.5a, sharper than Fact 37.6.5b for $R \geq 1.6405$, and sharper than Fact 37.6.5d whenever $R \leq 2.0462$.

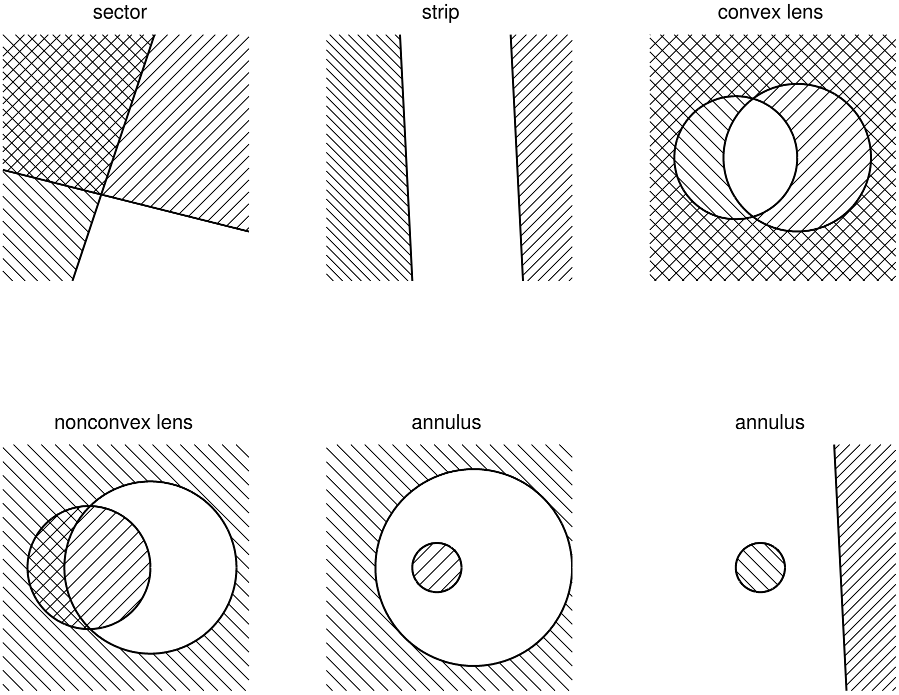

FIGURE 37.1 Six different configurations (in white) of intersections of two disks of the Riemann sphere.

Examples:

Consider the matrix

$$A = \begin{bmatrix} 1 & \gamma \\ 0 & 1 \end{bmatrix} \in \mathbb{C}^{2\times 2}, \quad \gamma = R - \frac{1}{R}, \quad R > 1,$$

with $\|A\| = \|A^{-1}\| = R$ such that both sets $\{|z| \leq R\}$ and $\{|z| \geq 1/R\}$ are spectral for A, and consider the intersection $X(R) = \{z \in \mathbb{C} : R^{-1} \leq |z| \leq R\}$.

1. [Mis84] The example of the function $f(z) = z - 1/z$, which verifies $\|f(A)\|/\|f\|_{X(R)} = 2\frac{R^2-1}{R^2+1}$, shows that $X(R)$ is not a spectral set for $R > \sqrt{3}$.
2. We get a sharper statement for the function $f(z) = g(z) - g(1/z)$, $g(z) = R\frac{z-1}{R^2-z}$, leading to

$$\|f(A)\| = 2, \quad \|f\|_{X(R)} = \frac{1+R^2+2R}{1+R^2+R} < \frac{4}{3}.$$

Thus, $X(R)$ is even not $\frac{3}{2}$-spectral for A for any $R > 1$. Compared with Fact 37.6.5c we thus have shown the improved lower bound $K(R) \geq 2\frac{1+R^2+R}{1+R^2+2R} > \frac{3}{2}$.

3. Let the boundary of the compact $X \subset \mathbb{C}$ consist of $n+1$ disjoint analytic Jordan curves. Then X is K-spectral for the above matrix A if and only if [Mis84]

$$K \geq \gamma\,\Gamma(X), \quad \Gamma(X) = \sup\Big\{\frac{|f'(1)|}{\|f\|_X} : f \text{ analytic on the interior of } X,\ f(1) = 0\Big\}.$$

For the annulus $X(R) = \{z \in \mathbb{C} : R^{-1} \leq |z| \leq R\}$ of the preceding example, the quantity $\Gamma(X(R))$ is computable [BBC09], leading to the lower bound of Fact 37.6.5c. Moreover, given $r \in (1, R)$, using the Schwarz lemma we also conclude that both sets $\{z : |z| \leq r\}$ and $\{z : |z| \geq 1/r\}$ are K-spectral for A with $K = (R - R^{-1})/(r - r^{-1})$ but not their intersection $X(r)$, at least for those r not too far from R.

37.7 The Numerical Range as a *K*-Spectral Set

Recall that the numerical range is given by $W(A) := \{\langle Ax, x\rangle : \|x\| = 1\}$. It has been conjectured [FW72] that the closure of the numerical range is a complete K-spectral set for A. This was proved in [DD99]. Here we report about recent results along these lines, including the existence of a universal such constant K shown by Crouzeix [Cro07]. For applications in numerical linear algebra of results of this type, see for instance the discussions in [Eie93, Gre97, TT99].

Facts:

1. Estimates depending on the shape of X: For every bounded linear operator $A \in \mathcal{L}(H)$, every compact convex set X containing the numerical range is a complete K-spectral set for A, where
   (a) [DD99] $K = 3 + (2\pi\,\text{diameter}(X)^2/\,\text{area}(X))^3$.
   (b) [PS05] $K = 1+2/(1-q(X))$, with $q(X) \in [0, 1]$ being C. Neumann's configuration constant of X (the oscillation norm of the underlying Neumann-Poincaré singular integral operator [Kra80]). We have $q(X) = 1$ if and only if X is a triangle or a quadrilateral.
   (c) [BCD06, Theorem 2.3] $K = 2 + \pi + TV(\log(r))$, if the boundary of X is parametrized by $[0, 2\pi] \ni t \mapsto \omega + r(t)e^{it}$, $r(t) \geq 0$.
2. Universal estimates:
   (a) [Cro07, Theorem 1] There exists a universal constant $K = K_{Crouzeix} \in [2, 11.08]$ such that for every bounded linear operator $A \in \mathcal{L}(H)$, the closure of the numerical range $\overline{W(A)}$ is a complete K-spectral set for A.
   (b) [Cro04a, Theorem 1.1] $W(A)$ is completely 2-spectral for every 2×2 matrix A.
3. Mapping theorems for the numerical range: let $A \in \mathcal{L}(H)$, and let f be analytic on $\mathbb{D}$, and continuous up to $\partial\mathbb{D}$.
   (a) [BS67] $w(A) \leq 1$ if and only if for all $z \in \mathbb{C}$

   $$\|A - zI\| \leq 1 + \sqrt{1 + |z|^2} = \left\| \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix} - zI \right\|.$$

   (b) [BS67] If $w(A) \leq 1$, $\|f\|_{\mathbb{D}} \leq 1$, and $f(0) = 0$ then $w(f(A)) \leq 1$.

(c) [Dru08] If $w(A) \leq 1$, $\|f\|_{\mathbb{D}} \leq 1$, and $|f(0)| < 1$, then $W(A)$ is a subset of the convex hull of the union of the disks $\overline{\mathbb{D}}$ and $\{z \in \mathbb{C} : |z - f(0)| \leq 1 - |f(0)|^2\}$. Furthermore, $\|f(A)\| \leq \nu(|f(0)|)$, where

$$\nu(\alpha) = \Big(2 - 3\alpha^2 + 2\alpha^4 + 2(1-\alpha^2)(1-\alpha^2+\alpha^4)^{1/2}\Big)^{1/2}.$$

(d) [Dru08] If $w(A) \leq 1$, then $w(f(A)) \leq \frac{5}{4}\|f\|_{\overline{\mathbb{D}}}$, and $\frac{5}{4}$ is the best possible constant.

(e) [Kat65] If r is a rational function with $r(\infty) = \infty$, and if $X = \{z \in \mathbb{C} : |r(z)| \leq 1\}$ is a convex set containing $W(A)$, then $w(r(A)) \leq 1$.

Open Problems:

1. [Cro07] Is $K_{Crouzeix} = 2$? At least if we restrict ourselves to 3×3 matrices?

Examples:

1. [Cla84] The spectrum of the Toeplitz operator T_ϕ acting on the Hardy space H^2 with symbol $\phi(w) = aw + bw^{-1}$, $0 < b < a$, is a convex set whose boundary is an ellipse with semi-axes $a \pm b$. The spectrum coincides with the closure of the numerical range $W(T_\phi)$. This set is not spectral but K-spectral for T_ϕ with $K = \sqrt{1 + |b/a|^2}$. Other classes of symbols with similar properties are given in [Cla84].
2. [PS05] The configuration constant of Fact 37.7.1b can be estimated for (smooth) X: $q(X) \leq 1 - \frac{1+e}{2}\sqrt{1-e^2}$ for ∂X an ellipse with eccentricity $e < 1$ and $q(X) \leq 1 - \frac{\text{length}(\partial X)}{2\pi R}$, with R the maximum radius of curvature.
3. K-spectral sets containing the numerical range: let $A \in \mathcal{L}(H)$, and let $X \subset \mathbb{C}$ be closed and convex containing $W(A)$.

   (a) [CD03, BCD06, BC07] If X is a convex sector or a strip, then X is $(2 + \frac{2}{\sqrt{3}})$-spectral for A.

   (b) [Cro04b, BC07] If the boundary of X is a parabola or a hyperbola, then X is $(2 + \frac{2}{\sqrt{3}})$-spectral for A.

   (c) [BC07, Theorem 1] If the boundary of X is an ellipse with eccentricity $e \leq 1$, then X is $(2 + \frac{2}{\sqrt{4-e^2}})$-spectral for A.

   (d) For an equilateral triangle, we have $K = 2+\pi+6\log(2)$ according to Fact 37.7.1c, and for a square $K = 2 + \pi + 4\log(2)$.

4. [Cro12b] For the 3×3 matrix

$$A = \begin{bmatrix} 0 & 2 & 0 \\ \epsilon & 0 & (1-\epsilon^2)/\sqrt{2} \\ 0 & 0 & (1-\epsilon^2)/\sqrt{2} \end{bmatrix}$$

   and sufficiently small $\epsilon > 0$, the numerical range $W(A)$ is 2-spectral for A but not completely 2-spectral for A.
5. [GC12] Crouzeix's conjecture is known to hold for generalized Jordan blocks where one replaces in a Jordan block of arbitrary size the lower left entry 0 by an arbitrary scalar.
6. For $f(z) = z$ we recover from Fact 37.7.2 the well-known link between numerical radius and Euclidean norm, namely $[1,2] \ni \|A\|/w(A) = \|f(A)\|/\sup_{z \in W(A)} |f(z)| \leq K_{Crouzeix}$.

7. Consider $A = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix} \in \mathbb{C}^{2\times 2}$, $f(A) = \begin{bmatrix} f(0) & 2f'(0) \\ 0 & f(0) \end{bmatrix}$. Here $W(A)$ is the closed unit disk and, for $f(z) = z$,

$$\|f(A)\| \Big/ \sup_{z\in W(A)} |f(z)| = 2 \leq K_{Crouzeix}.$$

8. [Cro04a, Sect. 2] Consider $A = \begin{bmatrix} 1 & \rho - \frac{1}{\rho} \\ 0 & -1 \end{bmatrix} \in \mathbb{C}^{2\times 2}$ with $\rho > 1$. According to Fact 25.1.7, $W(A)$ is compact, with its boundary given by an ellipse with foci ± 1 and minor axis $\rho - 1/\rho$. The matrix can be diagonalized as

$$A = LBL^{-1}, \quad B = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad L = \begin{bmatrix} 1 & -\frac{\rho - 1/\rho}{\rho + 1/\rho} \\ 0 & \frac{2}{\rho + 1/\rho} \end{bmatrix}, \quad \|L\|\,\|L^{-1}\| = \|A\| = \rho.$$

Thus

$$\frac{\|f(A)\|}{\sup_{z\in W(A)} |f(z)|} \leq \rho \frac{\|f(B)\|}{\sup_{z\in W(A)} |f(z)|} = \rho \frac{\max\{|f(-1)|, |f(1)|\}}{\sup_{z\in W(A)} |f(z)|}.$$

By [Cro04a, Theorem 2.1] and some elementary calculus, the right-hand side of this expression is maximized for the function f_0 mapping conformally $W(A)$ on the closed unit disk, with $f_0(0) = 0$, $f_0'(0) > 0$. Thus, $W(A)$ is a K-spectral set for A with optimal constant $K = \rho f_0(1) = \|f_0(A)\| \in (1, 2)$, the last two relations following from the fact that an explicit formula for f_0 is known [Cro04a, Eq. (2.2)].

37.8 Applications to the Approximate Computation of Matrix Functions

Facts:

Notation: $A \in \mathbb{C}^{n\times n}$, $\mathbb{E} \subset \mathbb{C}$ compact convex, being $K(\mathbb{E})$–spectral for A, f a function being analytic on $\mathbb{E}$.

1. Polynomial approximation through Taylor sums.
   A popular method [Hig08, Sect. 4.3] for approximately computing (entire) functions of matrices is to approach the Taylor series $f(z) = \sum_{j=0}^{\infty} c_j z^j$ by its mth partial sum $S_m(z) = \sum_{j=0}^{m} c_j z^j$, with the error estimate [Mat93, Cor. 2]

$$\|(f - S_m)(A)\| \leq \frac{1}{(m+1)!} \max_{0\leq t\leq 1} \|A^{m+1} f^{(m+1)}(tA)\|.$$

   Here the right-hand side can by bounded in terms of $\mathbb{E}$ by the techniques of the preceding subsections, see, e.g., Example 37.2.8 or Fact 37.7.2.

2. Polynomial approximation through Faber sums.

   Instead of Taylor sums, following [Hig08, Sect. 4.4.1] and Section 17.7 one may also consider best polynomial approximants p_m of f on $\mathbb{E}$, leading to the error estimate

$$\|(f - p_m)(A)\| \leq K(\mathbb{E})\, \rho_m(f, \mathbb{E}), \quad \rho_m(f, \mathbb{E}) = \min_{\deg p \leq m} \max_{z\in\mathbb{E}} |f(z) - p(z)|.$$

   According to [KP67, Theorem 4], this rate $\rho_m(f, \mathbb{E})$ is achieved up to some factor $\alpha \log(m) + \beta$ with explicit $\alpha, \beta > 0$ not depending on f nor on $\mathbb{E}$ by taking as p_m the

mth partial Faber series, which is defined as follows: let $\phi = \psi^{-1}$ map conformally the exterior of $\mathbb{E}$ onto the exterior of the closed unit disk $\mathbb{D}$, then the mth Faber polynomial F_m is defined as the polynomial part of the Laurent expansion of ϕ^m at ∞, and f has the Faber series

$$\sum_{j=0}^{\infty} f_j F_j(z), \quad f_m = \frac{1}{2\pi i} \int_{|w|=1} \frac{f(\psi(w))}{w^{m+1}} dw,$$

absolutely converging to f uniformly in $\mathbb{E}$ [KP67, Theorem 5]. Notice that for $\mathbb{E}$ a disk centered at 0 we recover Taylor series, and for $\mathbb{E} = [-1,1]$ Chebyshev orthogonal series [Tre12]. By [BR09, Sect. 3] one has the a posteriori bound $|f_{m+1}| \leq \rho_m(f,\mathbb{E}) \leq 2(|f_{m+1}|+|f_{m+2}|+\ldots)$. Estimates for the Faber coefficients of the exponential function can be found in [BR09, Sect. 4].
The Faber operator [Gai87]

$$\mathcal{F}(F)(z) = \sum_{j=0}^{\infty} f_j F_j(z), \quad F(w) = \frac{f_0}{2} + \sum_{j=1} f_j w^j$$

for functions F analytic on $\mathbb{D}$ maps polynomials of degree m to polynomials of degree m, in particular $\mathcal{F}(w^m)(z) = F_m(z)$ for $m \geq 1$. According to [Bec05], [BR09, Theorem 2.1]

$$\|\mathcal{F}(F)(A)\| \leq 2 \max_{w \in \mathbb{D}} |F(w)|,$$

allowing to relate best polynomial approximation of f on $\mathbb{E}$ to $\rho_m(\mathcal{F}^{-1}(f),\mathbb{D})$, and to derive error estimates for matrix functions which do not involve $K(\mathbb{E})$, e.g., for the mth partial Faber sum p_m [BR09, Theorem 3.2]

$$\|(f-p_m)(A)\| \leq 2 \sum_{j=m+1}^{\infty} |f_j|.$$

3. Polynomial Arnoldi method.

   The Arnoldi process is a popular method for approaching $f(A)b$ for some fixed vector $b \neq 0$ and large sparse A [Hig08, Sect. 13.2]. The mth approximant is given by the projection formula $V_m f(V_m^* A V_m) V_m^* b$, where $V_m \in \mathbb{C}^{n\times m}$ with columns spanning an orthonormal basis of the Krylov subspace $\mathrm{Span}\{b, Ab, \ldots, A^{m-1}b\}$. Typically, $m \ll n$, and hence $f(V_m^* A V_m)$ can be computed by some direct method. According to [Hig08, Lemma 13.4], this method is exact for f a polynomial of degree $\leq m-1$, and hence

   $$\epsilon_m := \frac{\|f(A)b - V_m f(V_m^* A V_m) V_m^* b\|}{\|b\|} \leq \|(f-p)(A)\| + \|(f-p)(V_m^* A V_m)\|$$

   for any polynomial p of degree $\leq m-1$. Supposing that $W(A) \subset \mathbb{E}$ (and thus $W(V_m^* A V_m) \subset \mathbb{E}$), we obtain by means of the techniques of Fact 37.8.2 that $\epsilon_m \leq 2\, K_{Crouzeix}\, \rho_{m-1}(f,\mathbb{E})$ or $\epsilon_m \leq 4\, \rho_{m-1}(\mathcal{F}^{-1}(f),\mathbb{D}) \leq 4 \sum_{j=m}^{\infty} |f_j|$, see [BR09, Proposition 3.1 and Theorem 3.2].

4. Rational approximants with free poles via (Faber-)Padé approximants.

   Another popular approach (see [Hig08, Sect. 4.4.2] and Section 17.7) for approaching matrix functions for functions f with singularities is to replace f by the rational function p/q with p, q polynomials of degree at most k, and m, respectively, $k \geq m-1$, such that the first $k+m+1$ terms in the Taylor expansion of $f - p/q$ at zero vanish. Here one hopes that the poles of this $[k|m]$ Padé approximant p/q do mimic the singularities of f. Though this approach is also applied for entire functions like the exponential function [Hig08, Sect. 10.7.4], the error is best understood for Markov functions

$$f(z) = c + \int_\alpha^\beta \frac{d\mu(x)}{z-x}, \quad c \in \mathbb{R}, \quad \mu \text{ some positive measure,}$$

where we suppose that $\beta < -w(A)$. This includes (up to some variable transformations) functions like $\log(z)$, $1/\sqrt{z}$ or more generally pth roots, $\operatorname{sign}(z)$, $\tanh(z)$, and others [BGM81, BR09]. By [ST92, Lemma 6.2.1], the denominator q has all its roots in $[\alpha, \beta]$, and the error may be represented as

$$f(z) - \frac{p}{q}(z) = \frac{z^{m+n+1}}{q(z)^2} \int_\alpha^\beta \frac{q(x)^2}{x^{m+n+1}} \frac{d\mu(x)}{z-x}.$$

Then the error on the disk $\{z \in \mathbb{C} : |z| \leq w(A)\}$ is minimal for $z = -w(A)$, and, using Example 37.2.8,

$$\|(f - \frac{p}{q})(A)\| \leq 2\,|(f - \frac{p}{q})(-w(A))|.$$

In general, sharper error bounds are obtained for $k \geq m$ by combining the above techniques with those of Fact 37.8.2, where we suppose in addition that $\mathbb{E}$ is symmetric with respect to the real axis. We first notice that, with f, also $\mathcal{F}^{-1}(f)$ is a Markov function [BR09, Theorem 6.1(a)]. Denoting by P/Q the $[k|m]$ Padé approximant of $\mathcal{F}^{-1}(f)$, the function $\mathcal{F}(P/Q)$ is rational with numerator degree $\leq k$ and denominator degree $\leq m$, called the $[k|m]$ Faber-Padé approximant [Ell83]. For $\mathbb{E} = [-1, 1]$ one recovers the so–called non-linear Chebyshev-Padé approximant [Sue09]. As above, we may bound for Markov functions the error through

$$\|\Big(f - \mathcal{F}(\frac{P}{Q})\Big)(A)\| \leq 2\,|\Big(\mathcal{F}^{-1}(f) - \frac{P}{Q}\Big)(-1)|.$$

5. Rational approximation with prescribed poles and rational Arnoldi.

   There exists a variant of the polynomial Arnoldi method Fact 37.8.3 where the columns of $Q_m \in \mathbb{C}^{n \times m}$ give an orthonormal basis of the rational Krylov subspace

   $$q(A)^{-1}\operatorname{Span}\{b, Ab, \ldots, A^{m-1}b\}$$

   for some fixed polynomial $q(z) = \prod_j (z - z_j)$ of degree $\leq m-1$ (and hence for $q = 1$ we recover the polynomial Arnoldi method). The computation of V_m and $V_m^* A V_m$ by some rational variant of the Arnoldi process [BR09] requires $(A - z_j I)^{-1} a$ for some vectors a, and this task of solving shifted linear systems is particularly trackable if q has a small number of multiple poles. As before we obtain

   $$\widetilde{\epsilon}_m := \frac{\|f(A)b - V_m f(V_m^* A V_m) V_m^* b\|}{\|b\|} \leq \|(f - \frac{p}{q})(A)\| + \|(f - \frac{p}{q})(V_m^* A V_m)\|$$

   for any polynomial p of degree $\leq m-1$ [BR09, Theorem 5.2]. Let $W(A) \subset \mathbb{E}$, and suppose that $\mathbb{E}$ is symmetric with respect to the real axis, and $z_j \notin \mathbb{E}$. For estimating the error we are left with the task of approaching f on $\mathbb{E}$ by a rational function with fixed denominator p/q. Notice that $p/q = \mathcal{F}(P/Q)$ with P a polynomial of degree at most $\leq m-1$, and $Q(w) = \prod_j (w - \phi(z_j))$ [Ell83]. Hence, $\widetilde{\epsilon}_m \leq 4\,\rho_{m-1}^{Q}(\mathcal{F}^{-1}(f), \mathbb{D})$, where

   $$\rho_{m-1}^{q}(f, \mathbb{E}) = \min_{\deg p \leq m-1} \max_{z \in \mathbb{E}} |f(z) - \frac{p}{q}(z)|,$$

see [BR09, Theorem 5.2]. For Markov functions f as in Fact 37.8.4, lower and upper bounds for $\rho^{Q}_{m-1}(\mathcal{F}^{-1}(f),\mathbb{D})$ are given in [BR09, Theorem 6.2], in particular the simple explicit bound

$$\rho^{Q}_{m-1}(\mathcal{F}^{-1}(f),\mathbb{D}) \leq \frac{1}{|\phi(\beta)|} \max_{z\in\mathbb{E}} |f(z)-f(\infty)| \max_{w\in[\phi(\alpha),\phi(\beta)]} \Big|\prod_j \frac{w-\phi(z_j)}{1-w\overline{\phi(z_j)}}\Big|.$$

Poles z_j minimizing the right-hand side should therefore be in $[\alpha,\beta]$, the set of singularities of f, and various configurations of poles minimizing the right-hand side have been considered in [BR09, Sect. 6].

6. Error bounds for GMRES and FOM for solving systems of linear equations.

   Both GMRES and FOM are iterative Krylov subspace methods for solving systems $Ax=b$ with A large and sparse (see Chapter 54). Here we may apply the techniques of the preceding sections for the Markov function $f(z)=1/z$ provided that $0\notin\mathbb{E}$, $\mathbb{E}$ containing $W(A)$. The residual of the mth iterate x_m^{GMRES} of GMRES with starting residual $r=b-Ax_0^{GMRES}$ satisfy [Bec05]

   $$\frac{\|b-Ax_m^{GMRES}\|}{\|r\|} = \min_{\deg p\leq m} \frac{\|p(A)r\|}{|p(0)|\,\|r\|} \leq \min\{1,\frac{2}{|F_m(0)|}\} \leq \frac{2+1/|\phi(0)|}{|\phi(0)|^m}$$

   with F_m the mth Faber polynomial of $\mathbb{E}$, and ϕ mapping conformally the exterior of $\mathbb{E}$ onto the exterior of the unit disk. The asymptotic convergence factor $1/|\phi(0)|<1$ can be computed for various shapes of $\mathbb{E}$. For instance [Bec05, BGT06], for positive definite $A+A^*$ considering the lens $\mathbb{E}=\{z\in\mathbb{C}:\mathrm{re}(z)\geq \mathrm{dist}(0,W(A)),|z|\leq w(A)\}$ we get $1/|\phi(0)|=2\sin(\beta/(4-2\beta/\pi))<\sin(\beta)$, with the angle $\beta\in(0,\pi/2)$ being defined by $\cos(\beta)=\frac{\mathrm{dist}(0,W(A))}{w(A)}$.

   The mth iterate of FOM (with starting vector x_0^{FOM} is a special case of the polynomial Arnoldi method Fact 37.8.3, namely $x_m^{FOM}=V_m(V_m^*AV_m)^{-1}V_m^*b$ or $f(z)=1/z$, and thus

   $$\frac{\|x_m^{FOM}-A^{-1}b\|}{\|b\|} \leq 4\eta_{m-1}(\mathcal{F}^{-1}(f),\mathbb{D}) \leq \frac{4|\phi(0)|^{-m}}{\mathrm{dist}(0,\mathbb{E})}.$$

38.1 Combinatorial Structure and Invariants

The **combinatorial structure of a matrix** generally refers to the locations of the nonzero entries of a matrix, or it might be used to refer to the locations of the zero entries. To study and take advantage of the combinatorial structure of a matrix, graphs are used as models. Associated with a matrix are several graphs that represent the combinatorial structure of a matrix in various ways. The type of graph (undirected graph, bipartite graph, digraph) used depends on the kind of matrices (symmetric, rectangular, square) being studied [BR91], [Bru92], [BS04]. Conversely, associated with a graph, bipartite graph, or digraph are matrices that allow one to consider it as an algebraic object. These matrices — their algebraic properties — can often be used to obtain combinatorial information about a graph that is not otherwise obtainable. These are two of three general aspects of **combinatorial matrix theory**. A third aspect concerns intrinsic combinatorial properties of matrices viewed simply as an array of numbers.

Definitions:

Let $A = [a_{ij}]$ be an $m \times n$ matrix.

A **strong combinatorial invariant** of A is a quantity or property that does not change when the rows and columns of A are permuted, that is, which is shared by all matrices of the form PAQ, where P is a permutation matrix of order m and Q is a permutation matrix of order n.

A less restrictive definition can be considered when A is a square matrix of order n.

A **weak combinatorial invariant** is a quantity or property that does not change when the rows and columns are simultaneously permuted, that is, which is shared by all matrices of the form PAP^T where P is a permutation matrix of order n.

The $(0,1)$-matrix obtained from A by replacing each nonzero entry with a 1 is the **pattern** of A. (In those situations where the actual value of the nonzero entries is unimportant, one may replace a matrix with its pattern, that is, one may assume that A itself is a $(0,1)$-matrix.)

A **line** of a matrix is a row or column.

A **zero line** is a line of all zeros.

The **term rank** of a $(0,1)$-matrix A is the largest size $\varrho(A)$ of a collection of 1s of A with no two 1s in the same line.

A **cover** of A is a collection of lines that contain all the 1s of A.

A **minimum cover** is a cover with the smallest number of lines. The number of lines in a minimum line cover of A is denoted by $c(A)$.

A **co-cover** of A is a collection of 1s of A such that each line of A contains at least one of the 1s.

A **minimum co-cover** is a co-cover with the smallest number of 1s. The number of 1s in a minimum co-cover is denoted by $c^*(A)$.

The quantity $\varrho^*(A)$ is the **largest size of a zero submatrix** of A, that is, the maximum of $r+s$ taken over all integers r and s with $0 \leq r \leq m$ and $0 \leq s \leq n$ such that A has an $r \times s$ zero (possibly vacuous) submatrix.

Facts:

The following facts are either elementary or can be found in Chapters 1 and 4 of [BR91].

1. These are strong combinatorial invariants:
   (a) The number of rows (respectively, columns) of a matrix.
   (b) The quantity $\max\{r, s\}$ taken over all $r \times s$ zero submatrices $(0 \leq r, s)$.
   (c) The maximum value of $r+s$ taken over all $r \times s$ zero submatrices $(0 \leq r, s)$.
   (d) The number of zeros (respectively, nonzeros) in a matrix.
   (e) The number of zero rows (respectively, zero columns) of a matrix.
   (f) The multiset of row sums (respectively, column sums) of a matrix.
   (g) The rank of a matrix.
   (h) The permanent (see Chapter 43) of a matrix.
   (i) The singular values of a matrix.
2. These are weak combinatorial invariants:
   (a) The largest order of a principal submatrix that is a zero matrix.
   (b) The number of A zeros on the main diagonal of a matrix.
   (c) The maximum value of $p+q$ taken over all $p \times q$ zero submatrices that do not meet the main diagonal.
   (d) Whether or not for some integer r with $1 \leq r \leq n$, the matrix A of order n has an $r \times n-r$ zero submatrix that does not meet the main diagonal of A.
   (e) Whether or not A is a symmetric matrix.
   (f) The trace $\operatorname{tr}(A)$ of a matrix A.
   (g) The determinant $\det A$ of a matrix A.
   (h) The eigenvalues of a matrix.
   (i) The multiset of elements on the main diagonal of a matrix.
3. $\varrho(A), c(A), \varrho^*(A),$ and $c^*(A)$ are all strong combinatorial invariants.
4. $\rho(A) = c(A)$.
5. A matrix A has a co-cover if and only if it does not have any zero lines. If A does not have any zero lines, then $\varrho^*(A) = c^*(A)$.
6. If A is an $m \times n$ matrix without zero lines, then $\varrho(A)+\varrho^*(A) = c(A)+c^*(A) = m+n$.
7. $\operatorname{rank}(A) \leq \varrho(A)$.
8. Let A be an $m \times n$ (0,1)-matrix. Then there are permutation matrices P and Q such that

$$PAQ = \begin{bmatrix} A_1 & X & Y & Z \\ O & A_2 & O & O \\ O & S & A_3 & O \\ O & T & O & O \end{bmatrix},$$

where A_1, A_2, and A_3 are square, possibly vacuous, matrices with only 1s on their main diagonals, and $\rho(A)$ is the sum of the orders of A_1, A_2, and A_3. The rows, respectively columns, of A that are in every minimum cover of A are the rows, respectively columns, that meet A_1, respectively A_2. These rows and columns together with either the rows that meet A_3 or the columns that meet A_3 form minimum covers of A.

Examples:

1. Let

$$A = \left[\begin{array}{cc|cc|c|cc} \mathbf{1} & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & \mathbf{1} & 0 & 1 & 0 & 0 & 1 \\ \hline 0 & 0 & \mathbf{1} & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & \mathbf{1} & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 1 & \mathbf{1} & 0 & 0 \\ \hline 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 \end{array}\right].$$

Then $\varrho(A) = c(A) = 5$ with the five **1**s in different lines, and rows 1, 2, and 5 and columns 3 and 4 forming a cover. The matrix is partitioned in the form given in Fact 8.

38.2 Square Matrices and Strong Combinatorial Invariants

In this section, we consider the strong combinatorial structure of square matrices.

Definitions:

Let A be a $(0,1)$-matrix of order n.

A collection of n nonzero entries in A no two on the same line is a **diagonal** of A (this term is also applied to nonnegative matrices).

The next definitions are concerned with the existence of certain zero submatrices in A.

A is **partly decomposable** provided there exist positive integers p and q with $p + q = n$ such that A has a $p \times q$ zero submatrix. Equivalently, there are permutation matrices P and Q and an integer k with $1 \leq k \leq n-1$ such that

$$PAQ = \begin{bmatrix} B & C \\ O_{k,n-k} & D \end{bmatrix}.$$

A is a **Hall matrix** provided there does not exist positive integers p and q with $p + q > n$ such that A has a $p \times q$ zero submatrix.

A has **total support** provided $A \neq O$ and each 1 of A is on a diagonal of A.

A is **fully indecomposable** provided it is not partly decomposable.

A is **nearly decomposable** provided it is fully indecomposable and each matrix obtained from A by replacing a 1 with a 0 is partly decomposable.

Facts:

Unless otherwise noted, the following facts can be found in Chapter 4 of [BR91].

1. [BS94] Each of the following properties is equivalent to the matrix A of order n being a Hall matrix:
   (a) $\rho(A) = n$, that is, A has a diagonal (*Frobenius–König theorem*).
   (b) For all nonempty subsets L of $\{1, 2, \ldots, n\}$, $A[\{1, 2, \ldots, n\}, L]$ has at least $|L|$ nonzero rows.

   (c) For all nonempty subsets K of $\{1, 2, \ldots, n\}$, $A[K, \{1, 2, \ldots, n\}]$ has at least $|K|$ nonzero columns.

2. Each of the following properties is equivalent to the matrix A of order n being a fully indecomposable matrix:
   (a) $\rho(A) = n$ and the only minimum line covers are the set of all rows and the set of all columns.
   (b) For all nonempty subsets L of $\{1, 2, \ldots, n\}$, $A[\{1, 2, \ldots, n\}, L]$ has at least $|L| + 1$ nonzero rows.
   (c) For all nonempty subsets K of $\{1, 2, \ldots, n\}$, $A[K, \{1, 2, \ldots, n\}]$ has at least $|K| + 1$ nonzero columns.
   (d) The term rank $\rho(A(i, j))$ of the matrix $A(i, j)$ obtained from A by deleting row i and column j equals $n - 1$ for all $i, j = 1, 2, \ldots, n$.
   (e) A^{n-1} is a positive matrix.
   (f) The determinant $\det A \circ X$ of the Hadamard product of A with a matrix $X = [x_{ij}]$ of distinct indeterminates over a field F is irreducible in the ring $F[\{x_{ij} : 1 \leq i, j \leq n\}]$.
3. Each of the following properties is equivalent to the matrix A of order n having total support:
   (a) $A \neq O$ and the term rank $\rho(A(i, j))$ equals $n - 1$ for all $i, j = 1, 2, \ldots, n$ with $a_{ij} \neq 0$.
   (b) There are permutation matrices P and Q such that PAQ is a direct sum of fully indecomposable matrices.
4. (*Dulmage–Mendelsohn Decomposition theorem*) If the matrix A of order n has term rank equal to n, then there exist permutation matrices P and Q and an integer $t \geq 1$ such that

$$PAQ = \begin{bmatrix} A_1 & A_{12} & \cdots & A_{1t} \\ O & A_2 & \cdots & A_{2t} \\ \vdots & \vdots & \ddots & \vdots \\ O & O & \cdots & A_t \end{bmatrix},$$

   where $A_1, A_2, \ldots, A_t$ are square fully indecomposable matrices. The matrices $A_1, A_2, \ldots, A_t$ are called the *fully indecomposable components* of A and they are uniquely determined up to permutations of their rows and columns. The matrix A has total support if and only if $A_{ij} = O$ for all i and j with $i < j$; A is fully indecomposable if and only if $t = 1$.
5. (*Inductive structure of fully indecomposable matrices*) If A is a fully indecomposable matrix of order n, then there exist permutation matrices P and Q and an integer $k \geq 2$ such that

$$PAQ = \begin{bmatrix} B_1 & O & \cdots & O & E_1 \\ E_2 & B_2 & \cdots & O & O \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ O & O & \cdots & B_{k-1} & O \\ O & O & \cdots & E_k & B_k \end{bmatrix},$$

   where $B_1, B_2, \ldots, B_k$ are fully indecomposable and $E_1, E_2, \ldots, E_k$ each contain at least one nonzero entry. Conversely, a matrix of such a form is fully indecomposable.
6. (*Inductive structure of nearly decomposable matrices*) If A is a nearly decomposable $(0, 1)$-matrix, then there exist permutation matrices P and Q and an integer p with

$1 \leq p \leq n-1$ such that

$$PAQ = \left[\begin{array}{cccccc|c} 1 & 0 & 0 & \cdots & 0 & 0 & \\ 1 & 1 & 0 & \cdots & 0 & 0 & \\ 0 & 1 & 1 & \cdots & 0 & 0 & \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & F_1 \\ 0 & 0 & 0 & \cdots & 1 & 0 & \\ 0 & 0 & 0 & \cdots & 1 & 1 & \\ \hline & & & F_2 & & & A' \end{array}\right],$$

where A' is a nearly decomposable matrix of order $n-p$, the matrix F_1 has exactly one 1 and this 1 occurs in its first row, and the matrix F_2 has exactly one 1 and this 1 occurs in its last column. If $n-p \geq 2$, and the 1 in F_2 is in its column j and the 1 in F_2 is in its row i, then the (i,j) entry of A' is 0.

7. The number of nonzero entries in a nearly decomposable matrix A of order $n \geq 3$ is between $2n$ and $3(n-1)$.

Examples:

1. Let

$$A_1 = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & 1 & 1 \end{bmatrix}, \; A_2 = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix}, \; A_3 = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \; A_4 = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{bmatrix}.$$

Then A_1 is partly decomposable and not a Hall matrix. The matrix A_2 is a Hall matrix and is partly decomposable, but does not have total support. The matrix A_3 has total support. The matrix A_4 is nearly decomposable.

38.3 Square Matrices and Weak Combinatorial Invariants

In this section, we restrict our attention to the weak combinatorial structure of square matrices.

Definitions:

Let A be a matrix of order n.

B is **permutation similar** to A if there exists a permutation matrix P such that $B = P^T AP$ $(= P^{-1}AP)$. A is **reducible** provided $n \geq 2$ and for some integer r with $1 \leq r \leq n-1$, there exists an $r \times (n-r)$ zero submatrix which does not meet the main diagonal of A, that is, provided there is a permutation matrix P and an integer r with $1 \leq r \leq n-1$ such that

$$PAP^T = \begin{bmatrix} B & C \\ O_{r,n-r} & D \end{bmatrix}.$$

A is **irreducible** provided that A is not reducible.

A is **completely reducible** provided there exists an integer $k \geq 2$ and a permutation matrix P such that $PAP^T = A_1 \oplus A_2 \oplus \cdots \oplus A_k$ where $A_1, A_2, \ldots, A_k$ are irreducible.

A is **nearly reducible** provided A is irreducible and each matrix obtained from A by replacing a nonzero entry with a zero is reducible.

A **Frobenius normal form** of A is a block upper triangular matrix with irreducible diagonal blocks that is permutation similar to A; the diagonal blocks are called the **irreducible components** of A. (cf. Fact 1.)

Facts:

The following facts can be found in Chapter 3 of [BR91].

1. (*Frobenius normal form*) There is a permutation matrix P and an integer $r \geq 1$ such that
$$PAP^T = \begin{bmatrix} A_1 & A_{12} & \cdots & A_{1r} \\ O & A_2 & \cdots & A_{2r} \\ \vdots & \vdots & \ddots & \vdots \\ O & O & \cdots & A_r \end{bmatrix},$$
where $A_1, A_2, \ldots, A_t$ are square irreducible matrices. The matrices $A_1, A_2, \ldots, A_r$ are the **irreducible components** of A and they are uniquely determined up to simultaneous permutations of their rows and columns.
2. There exists a permutation matrix Q such that AQ is irreducible if and only if A has at least one nonzero element in each line.
3. If A does not have any zeros on its main diagonal, then A is irreducible if and only if A is fully indecomposable. The matrix A is fully indecomposable if and only if there is a permutation matrix Q such that AQ has no zeros on its main diagonal and AQ is irreducible.
4. (*Inductive structure of irreducible matrices*) Let A be an irreducible matrix of order $n \geq 2$. Then there exists a permutation matrix P and an integer $m \geq 2$ such that
$$PAP^T = \begin{bmatrix} A_1 & O & \cdots & O & E_1 \\ E_2 & A_2 & \cdots & O & O \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ O & O & \cdots & A_{m-1} & O \\ O & O & \cdots & E_m & A_m \end{bmatrix},$$
where $A_1, A_2, \ldots, A_m$ are irreducible and $E_1, E_2, \ldots, E_m$ each have at least one nonzero entry.
5. (*Inductive structure of nearly reducible matrices*) If A is a nearly reducible $(0,1)$-matrix, then there exist permutation matrix P and an integer m with $1 \leq m \leq n-1$ such that
$$PAP^T = \left[\begin{array}{cccccc|c} 0 & 0 & 0 & \cdots & 0 & 0 & \\ 1 & 0 & 0 & \cdots & 0 & 0 & \\ 0 & 1 & 0 & \cdots & 0 & 0 & F_1 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \\ 0 & 0 & 0 & \cdots & 1 & 0 & \\ \hline & & & F_2 & & & A' \end{array}\right],$$
where A' is a nearly reducible matrix of order m, the matrix F_1 has exactly one 1 and it occurs in the first row and column j of F_1 with $1 \leq j \leq m$, and the matrix F_2 has exactly one 1 and it occurs in the last column and row i of F_2 where $1 \leq i \leq m$. The element in position (i, j) of A' is 0.
6. The number of nonzero entries in a nearly reducible matrix of order $n \geq 2$ is between n and $2(n-1)$

Examples:

1. Let
$$A_1 = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \ A_2 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \end{bmatrix}, \ A_3 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix}, \ A_4 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}.$$
Then A_1 is reducible but not completely reducible, and A_2 is irreducible. (Both A_1 and A_2 are partly decomposable.) The matrix A_3 is completely reducible. The matrix A_4 is nearly reducible.

38.4 The Class $\mathcal{A}(R, S)$ of $(0, 1)$-Matrices

In the next definition, we introduce one of the most important and widely studied classes of $(0, 1)$-matrices (see Chapter 6 of [Rys63] and [Bru80]).

Definitions:

Let $A = [a_{ij}]$ be an $m \times n$ matrix.

The **row sum vector** of A is $R = (r_1, r_2, \ldots, r_m)$, where $r_i = \sum_{j=1}^{n} a_{ij}$, $(i = 1, 2, \ldots, m)$.

The **column sum vector** of A is $S = (s_1, s_2, \ldots, s_n)$, where $s_j = \sum_{i=1}^{m} a_{ij}$, $(j = 1, 2, \ldots, n)$.

A real vector $(c_1, c_2, \ldots, c_n)$ is **monotone** provided $c_1 \geq c_2 \geq \cdots \geq c_n$.

The **class of all** $m \times n$ $(0, 1)$**-matrices with row sum vector** R **and column sum vector** S is denoted by $\mathcal{A}(R, S)$.

The class $\mathcal{A}(R, S)$ is a **monotone class** provided R and S are both monotone vectors.

An **interchange** is a transformation on a $(0, 1)$-matrix that replaces a submatrix equal to the identity matrix I_2 by the submatrix

$$L_2 = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

or vice versa.

If $\theta(A)$ is any real numerical quantity associated with a matrix A, then the **extreme values** of θ are $\bar{\theta}(R, S)$ and $\tilde{\theta}(R, S)$, defined by

$$\bar{\theta}(R, S) = \max\{\theta(A) : A \in \mathcal{A}(R, S)\} \text{ and } \tilde{\theta}(R, S) = \min\{\theta(A) : A \in \mathcal{A}(R, S)\}.$$

Let $T = [t_{kl}]$ be the $(m + 1) \times (n + 1)$ matrix defined by

$$t_{kl} = kl - \sum_{j=1}^{l} s_j + \sum_{i=k+1}^{m} r_i, \quad (k = 0, 1, \ldots, m; l = 0, 1, \ldots, n).$$

The matrix T is the **structure matrix** of $\mathcal{A}(R, S)$.

Facts:

The following facts can be found in Chapter 6 of [Rys63], [Bru80], Chapter 6 of [BR91], and Chapters 3 and 4 of [Bru06].

1. A class $\mathcal{A}(R, S)$ can be transformed into a monotone class by row and column permutations.
2. Let $U = (u_1, u_2, \ldots, u_n)$ and $V = (v_1, v_2, \ldots, v_n)$ be monotone, nonnegative integral vectors. $U \preceq V$ if and only if $V^* \preceq U^*$, and $U^{**} = U$ or U extended with 0s.
3. (*Gale–Ryser theorem*) $\mathcal{A}(R, S)$ is nonempty if and only if $S \preceq R^*$.
4. Let the monotone class $\mathcal{A}(R, S)$ be nonempty, and let A be a matrix in $\mathcal{A}(R, S)$. Let $K = \{1, 2, \ldots, k\}$ and $L = \{1, 2, \ldots, l\}$. Then t_{kl} equals the number of 0s in the submatrix $A[K, L]$ plus the number of 1s in the submatrix $A(K, L)$; in particular, we have $t_{kl} \geq 0$.
5. (*Ford–Fulkerson theorem*) The monotone class $\mathcal{A}(R, S)$ is nonempty if and only if its structure matrix T is a nonnegative matrix.
5. If A is in $\mathcal{A}(R, S)$ and B results from A by an interchange, then B is in $\mathcal{A}(R, S)$. Each matrix in $\mathcal{A}(R, S)$ can be transformed to every other matrix in $\mathcal{A}(R, S)$ by a sequence of interchanges.
6. The maximum and minimum term rank of a nonempty monotone class $\mathcal{A}(R, S)$ satisfy:
$$\bar{\rho}(R, S) = \min\{t_{kl} + k + l; k = 0, 1, \ldots, m, l = 0, 1, \ldots, n\},$$
$$\tilde{\rho}(R, S) = \min\{k + l : \phi_{kl} \geq t_{kl}, k = 0, 1, \ldots, m, l = 0, 1, \ldots, n\},$$
where
$$\phi_{kl} = \min\{t_{i_1, l+j_2} + t_{k+i_2, j_1} + (k - i_1)(l - j_1)\},$$
the minimum being taken over all integers i_1, i_2, j_1, j_2 such that $0 \leq i_1 \leq k \leq k + i_2 \leq m$ and $0 \leq j_1 \leq l \leq l + j_2 \leq n$.

8. Let $\text{tr}(A)$ denote the trace of a matrix A. The maximum and minimum trace of a nonempty monotone class $\mathcal{A}(R, S)$ satisfy:

$$\overline{\text{tr}}(R, S) = \min\{t_{kl} + \max\{k, l\} : 0 \leq k \leq m, 0 \leq l \leq n\},$$
$$\tilde{\text{tr}}(R, S) = \max\{\min\{k, l\} - t_{kl} : 0 \leq k \leq m, 0 \leq l \leq n\}.$$

7. Let k and n be integers with $0 \leq k \leq n$, and let $\mathcal{A}(n, k)$ denote the class $\mathcal{A}(R, S)$, where $R = S = (k, k, \ldots, k)$ (n k's). Let $\tilde{\nu}(n, k)$ and $\bar{\nu}(n, k)$ denote the minimum and maximum rank, respectively, of matrices in $\mathcal{A}(n, k)$.
   (a) $\bar{\nu}(n, k) = \begin{cases} 0, \text{ if } k = 0, \\ 1, \text{ if } k = n, \\ 3, \text{ if } k = 2 \text{ and } n = 4, \\ n, \text{ otherwise.} \end{cases}$
   (b) $\tilde{\nu}(n, k) = \tilde{\nu}(n, n - k)$ if $1 \leq k \leq n - 1$.
   (c) $\tilde{\nu}(n, k) \geq \lceil n/k \rceil$, $(1 \leq k \leq n - 1)$, with equality if and only if k divides n.
   (d) $\tilde{\nu}(n, k) \leq \lfloor n/k \rfloor + k$, $(1 \leq k \leq n)$.
   (e) $\tilde{\nu}(n, 2) = n/2$ if n is even, and $(n + 3)/2$ if n is odd.
   (f) $\tilde{\nu}(n, 3) = n/3$ if 3 divides n and $\lfloor n/3 \rfloor + 3$ otherwise.

Additional properties of $\mathcal{A}(R, S)$ can be found in [Bru80] and in Chapters 3 and 4 of [Bru06].

Examples:

1. Let $R = (7, 3, 2, 2, 1, 1)$ and $S = (5, 5, 3, 1, 1, 1)$. Then $R^* = (6, 4, 2, 1, 1, 1, 1)$. Since $5+5+3 > 6 + 4 + 2$, $S \not\preceq R^*$ and, by Fact 3, $\mathcal{A}(R, S) = \emptyset$.
2. Let $R = S = (2, 2, 2, 2, 2)$. The matrices

$$A = \begin{bmatrix} 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix} \text{ and } B = \begin{bmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix}$$

   are in $\mathcal{A}(R, S)$. Then A can be transformed to B by two interchanges:

$$\begin{bmatrix} 1 & \mathbf{1} & 0 & 0 & \mathbf{0} \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & \mathbf{0} & 0 & 1 & \mathbf{1} \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix} \to \begin{bmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & \mathbf{0} & \mathbf{1} & 1 & 0 \\ 0 & \mathbf{1} & \mathbf{0} & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix} \to \begin{bmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

38.5 The Class $\mathcal{T}(R)$ of Tournament Matrices

In the next definition, we introduce another important class of $(0, 1)$-matrices.

Definitions:

A $(0, 1)$-matrix $A = [a_{ij}]$ of order n is a **tournament matrix** provided $a_{ii} = 0$, $(1 \leq i \leq n)$ and $a_{ij} + a_{ji} = 1$, $(1 \leq i < j \leq n)$, that is, provided $A + A^T = J_n - I_n$.

The digraph of a tournament matrix is called a **tournament**.

Thinking of n teams $p_1, p_2, \ldots, p_n$ playing in a **round-robin tournament**, we have that $a_{ij} = 1$ signifies that team p_i beats team p_j.

The row sum vector R is also called the **score vector** of the tournament (matrix).

A **transitive tournament matrix** is one for which $a_{ij} = a_{jk} = 1$ implies $a_{ik} = 1$.

The **class of all tournament matrices with score vector** R is denoted by $\mathcal{T}(R)$.

A **δ-interchange** is a transformation on a tournament matrix that replaces a principal submatrix of order 3 equal to

$$\begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} \text{ with } \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$$

or vice versa.

Additional information on tournaments can be found in Chapter 45.

Facts:

The following facts can be found in Chapters 2 and 5 of [Bru06].

1. The row sum vector $R = (r_1, r_2, \ldots, r_n)$ and column sum vector $S = (s_1, s_2, \ldots, s_n)$ of a tournament matrix of order n satisfy $r_i + s_i = n - 1$, $(1 \leq i \leq n)$; in particular, the column sum vector is determined by the row sum vector.
2. If A is a tournament matrix and P is a permutation matrix, then PAP^T is a tournament matrix. Thus, one may assume without loss of generality that R is nondecreasing, that is, $r_1 \leq r_2 \leq \cdots \leq r_n$, so that the teams are ordered from worst to best.
3. (*Landau's theorem*) If $R = (r_1, r_2, \ldots, r_n)$ is a nondecreasing, nonnegative integral vector, then $\mathcal{T}(R)$ is nonempty if and only if

$$\sum_{i=1}^{k} r_i \geq \binom{k}{2}, \quad (1 \leq k \leq n)$$

   with equality when $k = n$. (A binomial coefficient $\binom{k}{s}$ is 0 if $k < s$.)
4. Let $R = (r_1, r_2, \ldots, r_n)$ be a nondecreasing nonnegative integral vector. The following are equivalent:
   (a) There exists an irreducible matrix in $\mathcal{T}(R)$.
   (b) $\mathcal{T}(R)$ is nonempty and every matrix in $\mathcal{T}(R)$ is irreducible.
   (c) $\sum_{i=1}^{k} r_i \geq \binom{k}{2}, (1 \leq k \leq n)$ with equality if and only if $k = n$.
5. If A is in $\mathcal{T}(R)$ and B results from A by a δ-interchange, then B is in $\mathcal{T}(R)$. Each matrix in $\mathcal{T}(R)$ can be transformed to every other matrix in $\mathcal{T}(R)$ by a sequence of δ-interchanges.
6. The rank, and so term rank, of a tournament matrix of order n is at least $n - 1$.
7. (*Strengthened Landau inequalities*) Let $R = (r_1, r_2, \ldots, r_n)$ be a nondecreasing nonnegative integral vector. Then $\mathcal{T}(R)$ is nonempty if and only if

$$\sum_{i \in I} r_i \geq \frac{1}{2} \sum_{i \in I} (i - 1) + \frac{1}{2} \binom{|I|}{2}, \quad (I \subseteq \{1, 2, \ldots, n\}),$$

   with equality if $I = \{1, 2, \ldots, n\}$.
8. Let $R = (r_1, r_2, \ldots, r_n)$ be a nondecreasing, nonnegative integral vector such that $\mathcal{T}(R)$ is nonempty. Then there exists a tournament matrix A such that the principal submatrices made out of the even-indexed and odd-indexed, respectively, rows and columns are transitive tournament matrices, that is, a matrix A in $\mathcal{T}(R)$ such that $A[\{1, 3, 5, \ldots\}]$ and $A[\{2, 4, 6, \ldots\}]$ are transitive tournament matrices.

Examples:

1. The following are tournament matrices:

$$A_1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \text{ and } A_2 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \end{bmatrix}.$$

   The matrix A_2 is a transitive tournament matrix.

2. Let $R = (2, 2, 2, 2, 3, 4)$. A tournament matrix in $\mathcal{T}(R)$ satisfying Fact 7 is

$$\begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 \\ 1 & 1 & 0 & 0 & 1 & 0 \\ 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 0 \end{bmatrix},$$

   since the two submatrices

$$A[|[1, 3, 5\}] = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \text{ and } A[\{2, 4, 6\}] = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 1 & 1 & 0 \end{bmatrix}$$

   are transitive tournament matrices.

38.6 Convex Polytopes of Doubly Stochastic Matrices

Doubly stochastic matrices (see Section 10.4) are widely studied because of their connection with probability theory, as every doubly stochastic matrix is the transition matrix of a Markov chain. The reader is referred to Chapter 39 for graph terminology.

Definitions:

Since a convex combination $cA + (1 - c)B$ of two doubly stochastic matrices A and B, where $0 \leq c \leq 1$, is doubly stochastic, the set Ω_n of doubly stochastic matrices of order n is a convex polytope in $\mathbb{R}^{n^2}$. Ω_n is also called the **assignment polytope** because of its appearance in the classical assignment problem.

If A is a $(0, 1)$-matrix of order n, then $\mathcal{F}(A)$ is the convex polytope of all doubly stochastic matrices whose patterns P satisfy $P \leq A$ (entrywise), that is, that have 0s at least wherever A has 0s.

The **dimension** of a convex polytope $\mathcal{P}$ is the smallest dimension of an affine space containing it and is denoted by $\dim \mathcal{P}$.

The **graph** $G(\mathcal{P})$ of a convex polytope $\mathcal{P}$ has the extreme points of $\mathcal{P}$ as its vertices and the pairs of extreme points of one-dimensional faces of $\mathcal{P}$ as its edges.

The **chromatic index** of a graph is the smallest integer t such that the edges can be partitioned into sets $E_1, E_2, \ldots, E_t$ such that no two edges in the same E_i meet.

A **scaling** of a matrix A is a matrix of the form $D_1 A D_2$, where D_1 and D_2 are diagonal matrices with positive diagonal entries.

If $D_1 = D_2$, then the scaling $D_1 A D_2$ is a **symmetric scaling**.

Let $A = [a_{ij}]$ have order n. A **diagonal product** of A is the product of the entries on a diagonal of A, that is, $a_{1j_1} a_{2j_2} \cdots a_{nj_n}$ where $j_1, j_2, \ldots, j_n$ is a permutation of $\{1, 2, \ldots, n\}$.

Facts:

The following facts can be found in Chapter 9 of [Bru06].

1. (*Birkhoff's theorem*) The extreme points of Ω_n are the permutation matrices of order n. Thus, each doubly stochastic matrix is a convex combination of permutation matrices.
2. The patterns of matrices in Ω_n are precisely the $(0,1)$-matrices of order n with total support.
3. The faces of Ω_n are the sets $\mathcal{F}(A)$, where A is a $(0,1)$-matrix of order n with total support. Ω_n is a face of itself with $\Omega_n = \mathcal{F}(J_n)$. The dimension of $\mathcal{F}(A)$ satisfies

   $$\dim \mathcal{F}(A) = t - 2n + k,$$

   where t is the number of 1s of A and k is the number of fully indecomposable components of A. The number of extreme points of $\mathcal{F}(A)$ (this number is the permanent $\mathrm{per}(A)$ of A), is at least $t-2n+k+1$. If A is fully indecomposable and $\dim \mathcal{F}(A) = d$, then $\mathcal{F}(A)$ has at most $2^{d-1}+1$ extreme points. In general, $\mathcal{F}(A)$ has at most 2^d extreme points.
4. The graph $G(\Omega_n)$ has the following properties:
   (a) The number of vertices of $G(\Omega_n)$ is $n!$. The degree of each vertex of $G(\Omega_n)$ is

   $$d_n = \sum_{k=2}^{n} \binom{n}{k}(k-1)!.$$

   (b) $G(\Omega_n)$ is connected and its diameter equals 1 if $n = 1, 2,$ and 3, and equals 2 if $n \geq 4$.
   (c) $G(\Omega_n)$ has a Hamilton cycle.
   (d) The chromatic index of $G(\Omega_n)$ equals d_n.
5. (*Hardy, Littlewood, Pólya theorem*) Let $U = (u_1, u_2, \ldots, u_n)$ and $V = (v_1, v_2, \ldots, v_n)$ be monotone, nonnegative integral vectors. Then $U \preceq V$ if and only if there is a doubly stochastic matrix A such that $U = VA$.
6. The set Υ_n of symmetric doubly stochastic matrices of order n is a subpolytope of Ω_n whose extreme points are those matrices A such that there is a permutation matrix P for which PAP^T is a direct sum of matrices each of which is either the identity matrix I_1 of order 1, the matrix $\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, or an odd order matrix of the type:

   $$\begin{bmatrix} 0 & 1/2 & 0 & 0 & \cdots & 0 & 1/2 \\ 1/2 & 0 & 1/2 & 0 & \cdots & 0 & 0 \\ 0 & 1/2 & 0 & 1/2 & \cdots & 0 & 0 \\ 0 & 0 & 1/2 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 0 & 1/2 \\ 1/2 & 0 & 0 & 0 & \cdots & 1/2 & 0 \end{bmatrix}.$$

7. Let A be a nonnegative matrix. Then there is a scaling $B = D_1 A D_2$ of A that is doubly stochastic if and only if A has total support. If A is fully indecomposable, then the doubly stochastic matrix B is unique and the diagonal matrices D_1 and D_2 are unique up to reciprocal scalar factors.
8. Let A be a nonnegative symmetric matrix with no zero lines. Then there is a symmetric scaling $B = DAD$ such that B is doubly stochastic if and only if A has total support. If A is fully indecomposable, then the doubly stochastic matrix B and the diagonal matrix D are unique.

9. Distinct doubly stochastic matrices of order n do not have proportional diagonal products; that is, if $A = [a_{ij}]$ and $B = [b_{ij}]$ are doubly stochastic matrices of order n with $A \neq B$, there does not exist a constant c such that $a_{1j_1}a_{2j_2}\cdots a_{nj_n} = cb_{1j_1}b_{2j_2}\cdots b_{nj_n}$ for all permutations $j_1, j_2, \ldots, j_n$ of $\{1, 2, \ldots, n\}$.

The subpolytopes of Ω_n consisting of (i) the convex combinations of the $n!-1$ nonidentity permutation matrices of order n and (ii) the permutation matrices corresponding to the even permutations of order n have been studied (see [Bru06]).

Polytopes of matrices more general than Ω_n have also been studied, for instance, the nonnegative generalizations of $\mathcal{A}(R, S)$ consisting of all nonnegative matrices with a given row sum vector R and a given column sum vector S (see Chapter 8 of [Bru06]).

Examples:

1. Ω_2 consists of all matrices of the form

$$\begin{bmatrix} a & 1-a \\ 1-a & a \end{bmatrix}, \quad (0 \leq a \leq 1).$$

All permutation matrices are doubly stochastic.

2. The matrix

$$\begin{bmatrix} 1/2 & 1/4 & 1/4 \\ 1/6 & 1/3 & 1/2 \\ 1/3 & 5/12 & 1/4 \end{bmatrix}$$

is a doubly stochastic matrix of order 3.

3. If

$$A = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix},$$

then

$$\begin{bmatrix} 1/2 & 1/2 & 0 \\ 0 & 1/2 & 1/2 \\ 1/2 & 0 & 1/2 \end{bmatrix}$$

is in $\mathcal{F}(A)$.

The first two sections of this chapter give a short introduction to graph theory. Unfortunately much graph theoretic terminology is not standard, so we had to choose. We allow, for example, graphs to have multiple edges and loops, and call a graph simple if it has none of these. On the other hand, we assume that graphs are finite.

For all nontrivial facts, references are given, sometimes to the original source, but often to textbooks or survey papers. A recent global reference for this chapter is [BH12].

39.1 Graphs: Basic Notions

Definitions:

A **graph** $G = (V, E)$ consists of a finite set $V = \{v_1, \ldots, v_n\}$ of **vertices** and a finite multiset E of **edges**, where each edge is a pair $\{v_i, v_j\}$ of vertices (not necessarily distinct). If $v_i = v_j$, the edge is called a **loop**. A vertex v_i of an edge is called an **endpoint** of the edge.

The **order** of graph G is the number of vertices of G.

A **simple graph** is a graph with no loops where each edge has multiplicity at most one.

Two graphs (V, E) and (V', E') are **isomorphic** whenever there exist bijections $\phi : V \to V'$ and $\psi : E \to E'$, such that $v \in V$ is an endpoint of $e \in E$ if and only if $\phi(v)$ is an endpoint of $\psi(e)$.

A **walk** of **length** ℓ in a graph is an alternating sequence $(v_{i_0}, e_{i_1}, v_{i_1}, e_{i_2}, \ldots, e_{i_\ell}, v_{i_\ell})$ of vertices and edges (not necessarily distinct), such that $v_{i_{j-1}}$ and v_{i_j} are endpoints of e_{i_j} for $j = 1, \ldots, \ell$.

A **path** of **length** ℓ in a graph is a walk of length ℓ with all vertices distinct.

A **cycle** of **length** ℓ in a graph is a walk $(v_{i_0}, e_{i_1}, v_{i_1}, e_{i_2}, \ldots, e_{i_\ell}, v_{i_\ell})$ with $v_{i_0} = v_{i_\ell}$, $\ell \neq 0$, and $v_{i_1}, \ldots, v_{i_\ell}$ all distinct.

A **Hamilton cycle** in a graph is a cycle that includes all vertices.

A graph (V, E) is **connected** if $V \neq \emptyset$ and there exists a walk between any two distinct vertices of V.

The **distance** between two vertices v_i and v_j of a graph G (denoted by $d_G(v_i, v_j)$ or $d(v_i, v_j)$) is the length of a shortest path between v_i and v_j. ($d(v_i, v_j) = 0$ if $i = j$, and $d(v_i, v_j)$ is infinite if there is no path between v_i and v_j.)

The **diameter** of a connected graph G is the largest distance that occurs between two vertices of G.

A **tree** is a connected graph with no cycles.

A **forest** is a graph with no cycles.

A graph (V', E') is a **subgraph** of a graph (V, E) if $V' \subseteq V$ and $E' \subseteq E$. If E' contains all edges from E with endpoints in V', (V', E') is an **induced** subgraph of (V, E).

A **spanning subgraph** of a connected graph (V, E) is a subgraph (V', E') with $V' = V$, which is connected.

A **spanning tree** of a connected graph (V, E) is a spanning subgraph, which is a tree.

A **connected component** of a graph (V, E) is an induced subgraph (V', E'), which is connected and such that there exists no edge in E with one endpoint in V' and one outside V'. A connected component with one vertex and no edge is called an **isolated vertex**.

Two graphs (V, E) and (V', E') are **disjoint** if V and V' are disjoint sets.

Two vertices u and v are **adjacent** if there exists an edge with endpoints u and v. A vertex adjacent to v is called a **neighbor** of v.

The **degree** or **valency** of a vertex v of a graph G (denoted by $\delta_G(v)$ or $\delta(v)$) is the number of times that v occurs as an endpoint of an edge (that is, the number of edges containing v, where loops count as 2).

A graph (V, E) is **bipartite** if the vertex set V admits a partition into two parts, such that no edge of E has both endpoints in one part (thus, there are no loops). More information on bipartite graphs is given in Chapter 41.

A simple graph (V, E) is **complete** if E consists of all unordered pairs from V. The (isomorphism class of the) complete graph on n vertices is denoted by K_n.

A graph (V, E) is **empty** if $E = \emptyset$. If also $V = \emptyset$, it is called the **null graph**.

A bipartite simple graph (V, E) with nonempty parts V_1 and V_2 is **complete bipartite** if E consists of all unordered pairs from V with one vertex in V_1 and one in V_2. The (isomorphism class of the) complete bipartite graph is denoted by K_{n_1,n_2}, where $n_1 = |V_1|$ and $n_2 = |V_2|$.

The (isomorphism class of the) simple graph that consists only of vertices and edges of a path of length ℓ is called **the path of length** ℓ, and denoted by $P_{\ell+1}$.

The (isomorphism class of the) simple graph that consists only of vertices and edges of a cycle of length ℓ is called **the cycle of length** ℓ, and denoted by C_ℓ.

The **complement** of a simple graph $G = (V, E)$ is the simple graph $\overline{G} = (V, \overline{E})$, where $\overline{E}$ consists of all unordered pairs from V that are not in E.

The **union** $G \cup G'$ of two graphs $G = (V, E)$ and $G' = (V', E')$ is the graph with vertex set $V \cup V'$, and edge (multi)set $E \cup E'$.

The **intersection** $G \cap G'$ of two graphs $G = (V, E)$ and $G' = (V', E')$ is the graph with vertex set $V \cap V'$, and edge (multi)set $E \cap E'$.

The **join** $G + G'$ of two disjoint graphs $G = (V, E)$ and $G' = (V', E')$ is the union of $G \cup G'$ and the complete bipartite graph with vertex set $V \cup V'$ and partition $\{V, V'\}$.

The **strong product** $G \cdot G'$ of two simple graphs $G = (V, E)$ and $G' = (V', E')$ is the simple graph with vertex set $V \times V'$, where two distinct vertices are adjacent whenever in both coordinate places the vertices are adjacent or equal in the corresponding graph. The strong product of ℓ copies of a graph G is denoted by G^ℓ.

Facts:

The facts below are elementary results that can be found in almost every introduction to graph theory, such as [Har69] or [Wes01].

1. For any graph, the sum of its degrees equals twice the number of edges; therefore, the number of vertices with odd degree is even.
2. For any simple graph, at least two vertices have the same degree.
3. A graph G is bipartite if and only if G has no cycles of odd length.

4. A tree with n vertices has $n-1$ edges.
5. A graph is a tree if and only if there is a unique path between any two vertices.
